INDEX TO VOLUME XV.

A

Acceleration: Best Method of securing [Lundie] 228
——City & South London Railway, on [McMahon] *391
——Tests in Cleveland..... 363
——See also Train Resistance.
Accidents: Amusing Letters about..... 92
——Blanks at Brisbane..... *443
——Cases, Bribery and Perjury in [Hodge].. a 239
—— Peculiar in Australia..... 352
—— Peculiar Testimony, Editorial on..... 579
——Instructions in New Orleans..... 289
——Legal Liability to Linemen [Hodge].... a 166
——Report System in Milwaukee..... 444
——Stratford, Conn., at..... a 599
Accountant's Association, Street Railway: Chicago Convention.
—— Address of President..... 804
—— Notes and Comments on [Kittredge]. 784
—— Papers and Reports of..... 797
—— Program of.....246, *674
——Collection of Blanks and Forms....32, 186, 799
——Officers and Executive Committee..... *676
Accounts: Accident, in Brisbane..... *443
—— In Milwaukee..... 444
——Balance Sheet System of..... 756
——Ideal System of [Kittredge].....30, c 91
——Repair Shop, for Small Road..... *442
——Standard System of..c 149, 521, a 536, a 596, 799 806, 807
——Store Room in Hartford..... *575
Accumulators, see Storage Batteries.
Advertising Bureau (Manufacturers)..... a 47
Air Brakes, see Brakes, Air.
Air Power, see Compressed Air.
Albany, Consolidation with Troy System.... a 600
Algiers, Electric Railways in..... *209
Allgemeine Elektricitäts Gesellschaft, Works of.....i 381, *719
Aluminum: Electrical Uses of.....113, 732
——Editorial on..... 95
America, Electric Railway Practice in..... *613
——Gross Receipts per Capita and Mile of Track in Cities of..... 227
American Street Railway Association: Chicago Convention.....540, a 597
—— Attendants at..... a 814
—— Banquet of..... 774
—— Entertainments 775
—— Exhibits at *817
—— Notice regarding Exhibits..... 261
—— Papers read at..... 789
—— Proceedings of..... 757
—— Program of 151, *674
——Editorial on..... 776
——Officers and Executive Committee of.... *675
——Standard Rules and Regulations of..c 89, c 146, c 216, c 285, c 365
American Steel & Wire Co..... 708
Among the Manufacturers.....65, 123, 196, 262, 336 418, 491, 550, 610, 752, 843, 900
Amusements, see Parks and Pleasure Resorts.
Anger, John E..... 123
Annual Reports, Atlanta Consolidated Street Railway ..... a 244
——Boston, Columbus and Chicago Railway Companies ..... a 105
——Brooklyn Rapid Transit Company..... a 604
——General Electric Co..... 331
——New York City Companies..... 898
——Sixteen British Tramway Companies..... i 170
——Washington Railways..... a 172
Arc Electric Headlight (Wellman)..... *322
Argentine Republic, see Buenos Ayres.
Armature Hoists and Jacks in Montreal.....c *221
Armatures, Repair of, see Repair Shops.
Atlanta: Atlanta Railway & Power Co., New Plans of 519
——Consolidated Street Railway Co., Annual Report of ..... a 244
——Street Railway Complications in..... 541
——Street Railway Contest in..... a 600
Australia: Accident Case in..... 352
——Brisbane, Accident Blanks in..... *443
——Light Railway Car in New South Wales.. *502
——Perth, New Plant in..... *454
——Tramway Matters in [Noyes]..... i 384
——Tramways in New South Wales, Report on ..... i 237
Austria: Czernowitz, Railway and Lighting System of [Ziffer]..... i *301
——Light Railways and Tramways in [Ziffer] i 236
——New Railways in [Ziffer]..... i *41
——Notes from ..... i 884
——Recent Decrees affecting Street Railways. i 602
——Recent Franchises in..... i 460
——Trieste, Light Railways in [Ziffer]..... i 383
——See also Hungary and Vienna.
Austria-Hungary, Electric Railway Practice in [Ziffer] *685
Automobiles: Editorial on Possibilities of... 224
——Motors for (Siemens-Halske)..... *736
Axles: Breaking of [Thompson]..... *211
——Letters on ..... c 288

B

Babbitt Melting Forge..... c 288
Baltimore: City Passenger Railway, Parlor Car for *189
——Consolidation in 52
——Feeder Conduits in..... *193
Barcelona, see Spain.
Bearings: Lubrication for (Keystone)..... 325
——Lubrication of [Hobart]..... *213
Belgium: Light Railways in Brussels..... i 380
——Tervueren-Brussels Electric Railway..... i 380
Belts, Compound to Prevent Slipping (Cling Surface) *328
Bennett, S. H..... 752
Berlin, Conn., Entertainment at..... 398
Berlin, Germany: Combination Car and Omnibus in *867
——Earnings of Railway Companies..... i 885
——Measurements of Voltage Drop in..... i 382
——New Elevated Electric Railway in..... 871
——Power Stations in..... 864
Black, Charles N..... 610
Blackwell & Co., Ltd., R. W. Organization of 897
Blanks, see Accounts.
Block Signal System for Single-Track Roads (Ramsey) *259
Boiler Tube Cleaner (Chicago B. C. Co.).... *253
——(Union) *118, 545
Boilers: Combustion, New Process of (Schlicht) *840
——Sectional (New York Safety)..... 389
——Worthington *60
Boiler Works, Reorganization of Company (Nat. W. T. Boiler Co.)..... 608
Böker, H. H., Works of..... *740
Bonds, see Rail Bonds.
Boosters or Storage Batteries [Adams]..... 214
Boston Elevated Railway Company, Annual Report of ..... a 105
——4000-h.p. Engine in.....*894
——Large Engine Shaft for..... *544
——Large Installation of Special Work in.... *868
——New Subway Proposed in..... 234
——South Terminal Station in..... *158
—— Editorial on..... 152
Boutell, F. H. Chevalier..... 491
Bowen, M. K..... *334
Braintree & Weymouth Street Railway, Car for *738
Brake Handle, Ratchet (Brill)..... *725
Brakes, Air: In Europe..... *495
——Improvements in (Standard)..... *723
——Rotary Compressor (Westinghouse)..... *707
——Storage System (Magann).....*59, 748
—— Test of *329
——Third Avenue Railway, New York, for (Standard) *257
——Works of Christensen Co..... 747
Brakes, Electric: Improvements in (G. E. Co.) *721
——New (Hubbard)..... 838
——Pittsburgh, in (G. E.)..... *138
Brakes, Mechanical: (Sterling)..... 485
——New (Duff) *255
——New (McCollum) *840
Brakes, Official Tests of, in New York..... a 303
Brake Shoes, Demand for (Compo)..... 411
——Truing Flat Wheels (Griffin)..... *62
Brazil: Bahia Electric Railway..... *207
——Para, Notes About..... 868
——Sao Paulo Electric Railway..... *449
Brill, John A. Interview with, on Foreign Practice in Rolling Stock..... 869
Brooklyn Rapid Transit Co., Annual Report. 604
——Changes in 89
——Combination Car for (Brill)..... *120
——Financial Analysis of..... 370
——New Traffic Arrangement in..... a 886
——Open Car for (Brill)..... *411
——Proportioning Feeders on Nassau Railroad [Dexter]..... *34
——Strike.....522, a 531
——Train Service on [McCormack]..... *790
Buenos Ayres: Belgrano Electric Tramway, Construction of *588
——Electric Railway Practice in [Manville].. *693
——Hand Truck in..... *62
——La Capital Traction System..... *69
Buffalo: Consolidation in.....162, 417
——Electric Welding of Rail Joints in....*362, *587
——High Speed Road from Tonawanda..... 852
——Trough for Steam Railroad Crossings.... *276
Bullock Electric Co., Works of..... *488

C

Cable, Largest in the World..... 838
Cahoon, J. B..... 550
Calendars for 1899.....52, 115
Camden, New Car for..... *476
Car Axles, see Axles.
Carbon Works, New (Speer)..... 716
Car Cleaning, Soap for (Modoc)..... 739
Car Couplers, Automatic (Van Dorn)..... *744
Car Equipments: Testing of [Herrick]..... *179
Car Houses: Car Hoists and Jacks in Brooklyn .....c *221
——Consolidated Traction Co., Pittsburgh.... *127
——Door Catch for, in Hartford..... *88
——Heating of (Sturtevant)..... *187
——New, in Hartford..... *573
Car Mileage as a Unit [Mackay]..... 797
——Editorial on 780
Cars, American Practice in..... 616
——Atlantic City, Open..... *893
——Argentina, Practice in [Manville]..... *698
——Austria-Hungary, Practice in [Ziffer].... *688
——Birmingham, Closed..... *114
——Braintree, Open..... *738
——Brooklyn, Open *411
——Camden, Closed *476
——Care of [Vander Veer]..... *796
——Chicago, in..... *632
——Chicago City Railway, Closed.....487, *569
——Cleveland, Closed..... *745
——Cleveland City Railway, Closed..... *895
——Combination (Brill).....*62, *120
——Combination Car and Omnibus (Siemens & Halske)..... *867
——Comparison of Different Types [Higgins] 313
——Convertible .....c *24, *820
——Double Deck for Bolton, Eng..... i *164
—— Hull, Eng., for..... *321
—— Syracuse, for..... *577
——France, Open..... *255
——German Practice in [Magee]..... *655
——Grab Handles, see Grab Handles.
——Great Britain, Practice in [Short]..... *671
——Hydro Carbon..... *323
——Interurban, near Detroit..... *7
——Interview with Mr. Brill on Export Trade in 869
——Lancaster, Pa., Closed..... *183
——Legal Requirements for Accommodations in [Hodge]..... a 102
——Lewiston & Youngstown Frontier Railway, Freight..... *892
——Liverpool, Large Order in..... 898
——Manufactured in 1898..... 93
——Mileage and Capitalization in America... 101
——Mexico, Closed..... *839
—— Funeral *547
——Montreal, Novel Open..... *506
——New South Wales, Light Railway..... *502
——Newton, Mass., Closed..... *56
——New York for Compressed Air Motors.. *188
——Parlor Car in Baltimore..... *189
—— New Brunswick, N. J..... *325
——Private, Rates charged in Rochester..... a 531
——Roller Bearings for, see Roller Bearings.

Abbreviations: * illustrated, c correspondence, a American edition only, i international edition only.

——St. Louis & Belleville, Closed..... *252
——Splicing in Philadelphia.....81, *571
——Trailer Connecter for (Central Electric).. *545
——Vestibules, Arguments against [McNamara]..... a 243
—— Not recommended in New York City. 194
——Width allowed in Germany..... 367
——Wilkes Barre, Trailer..... *727
Car Steps, Non-slipping (American Mason Safety Tread Co.)..... *716
Car Works: H. H. Böker, of..... *740
——Preston, England, at..... *729
——St. Louis, in (St. Louis Car Co.)..... *190
Cast Welding, see Rail Joints.
Ceylon, Electric Railway in..... i *533
Chicago: Annual Reports of Railway Companies ..... a 105
——City Railway, Car for.....487, *569
—— Repair Shops..... *565
—— Records of..... 222
—— State Street Line..... 519
——Compressed Air Cars in.....*414, 547
——Consolidated Traction Co., Organization of 333
——Consolidation in..... 52
——Convention at, see American Street Railway Association and Accountants' Street Railway Association.
——Electrical Exposition in..... 457
——Electric Traction Co. System of..... *559
——Fountain for Lincoln Park..... *327
——Franchises in..... a 107
——General Railway Company, Experiment with Low Fares..... *864
——Lake Street Elevated Railway, Tests of Railway Motors on (Chapman)..... 637
——Large Supply House in (Electric Appliance Co.)..... 327
——Northwestern Elevated Railway, Description of..... *642
—— Power Station of..... *452
——Sans Souci Park.....a *235
——South Chicago City Railway, Portable Oven *118
——South Side Elevated Railway: Feeder System *112
—— Financial Results of [Sprague]..... 470
——Street Railway Systems of..... *617
——Underground Conduits for..... 489
——Union Traction Co., Repair Shops of..*509, *562
—— Western Avenue Station, New Generator *429
——Works of Siemens-Halske Co. in..... *734
Christensen Engineering Co., Works of..... 747
Chronology of Modern Electric Railway Operation [Sprague]..... 471
Cicott, F. X..... 336
Cincinnati: Street Railway Co., Notes on.*433, *507

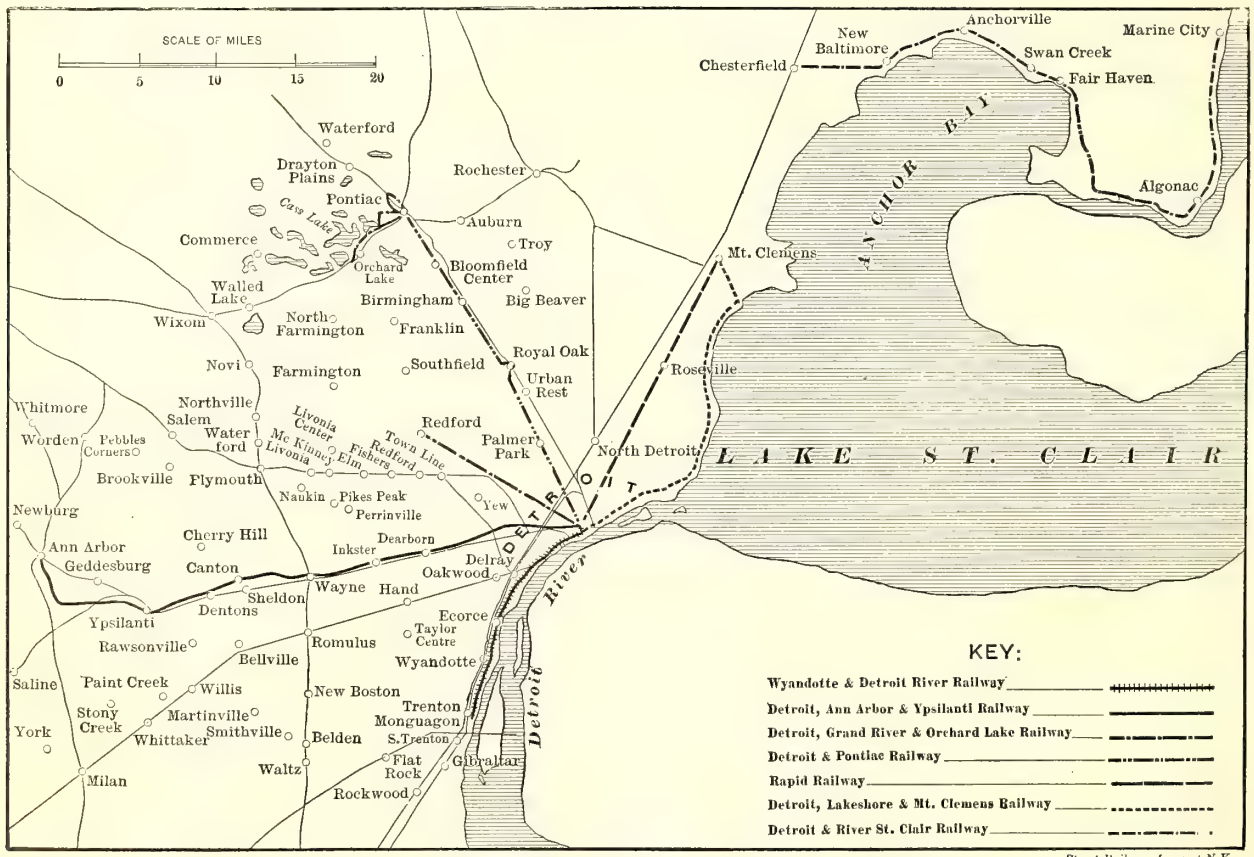
Street Railway Journal

VOL. XV. NEW YORK AND CHICAGO, JANUARY, 1899. No. 1.

THE INTERURBAN ELECTRIC RAILWAYS AROUND DETROIT

The interurban electric railway system around Detroit is more extensive than that in the neighborhood of any other city in this country, with the possible exception of Cleveland. There are no less than six interurban lines reaching out from the city in all directions, except where limited by the Detroit River, and of lengths varying from 20 to 40 miles. The cars are nearly all of the long double truck type; when outside of the city limits they run at schedule speeds of from 30 to 40 miles an hour and, in some instances, exceed this. The tracks usually follow the highway, being built at the side, so as not to occupy the portion devoted to vehicles, and, as a general thing, on toll roads during the last year, and, while the owners of all the lines prefer not to make public any financial statements of the operation of the roads, it is apparent that most of them are doing a good business, and practically all the companies are planning important extensions in the early future.

The headway on most of the lines is thirty minutes, and the cars run on regular published timetables, giving a service more closely resembling that of steam railroads than that of ordinary city electric railways. All the companies



POWER STATION—DETROIT, YPSILANTI & ANN ARBOR RAILWAY

whose owners are identical with or closely allied to those of the electric railway. Within the city the cars operate by a traffic arrangement over the lines of the Detroit Citizens' Railway Company, which controls all of the lines in that city, and all start from or near the central square in Detroit, around which they make a loop; while on the lines of this company the cars are operated by employees of the Detroit Citizens' Street Railway Company, which takes the local fares and pays the interurban railways a certain mileage for the use of the cars. Upon arriving at the city limits, or at the terminus of the Detroit Citizens' Railway lines, the crews are changed and employees of the interurban lines assume the operation of the cars.

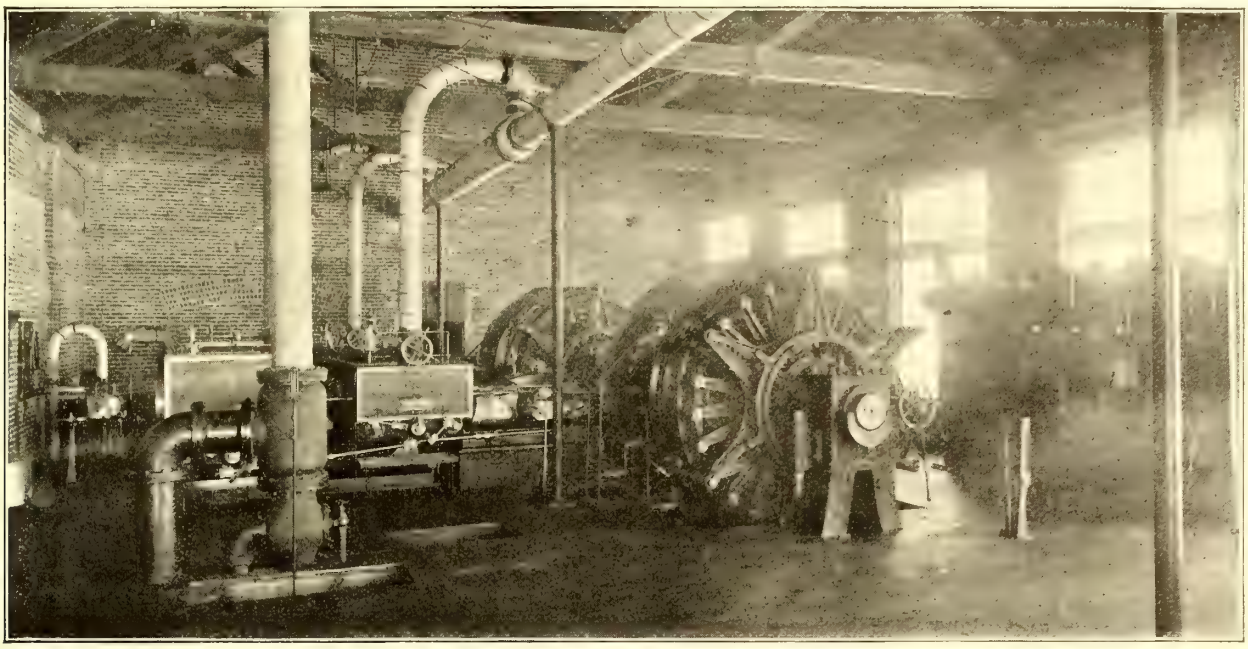
Two of the five most important lines have been built have offices in the city at which tickets can be purchased, and on one of the lines, mileage books are sold, though the coupons are detached in multiples of five. On one or two of the others duplicate fare receipts are issued by the conductor when fare is paid on the cars. All the roads are divided into 5-cent zones, and the average fare charged is about a cent a mile. Many, if not all, of the lines parallel steam railroads, and, although the running time between termini does not equal in point of speed that of the steam railroads, the frequency of the service, the ability to discharge passengers along the line and the low fares, have attracted considerable traffic from the steam rivals. The electric roads undoubtedly have also created a great deal of traffic.

Nearly all of the lines carry baggage and operate a light express system, and some operate regular freight trains, which they are entitled to do under the laws of the State of Michigan. These freight cars are of the regular box type, but neatly painted, and are run either as motor cars or as single trail cars, usually at night. Stations for the receipt of express and freight matter are located in the cities through which they pass. A considerable item of freight from the country into the city is milk, which is collected at points along the line in the early morning and delivered to depots in the city, where it is distributed in the usual way.

In spite of the long distances involved, it is interesting to note that no attempt has been yet made to transmit and distribute power by the alternating current system. The standard voltage on the trolley wire varies from 500 to 650, but the drop on the long lines is cared for by boosters, with which the stations of nearly all the companies are equipped.

MAP OF INTERURBAN ELECTRIC RAILWAYS NEAR DETROIT

One outlying line, the Detroit & River St. Clair Railway, which extends from Chesterfield to Marine City, is now operated by steam power, the trains coming in from Chesterville on the tracks of the Michigan Central Railroad. The electrical equipment of this line and its extension to Mt. Clemens at an early date, is probable, however.



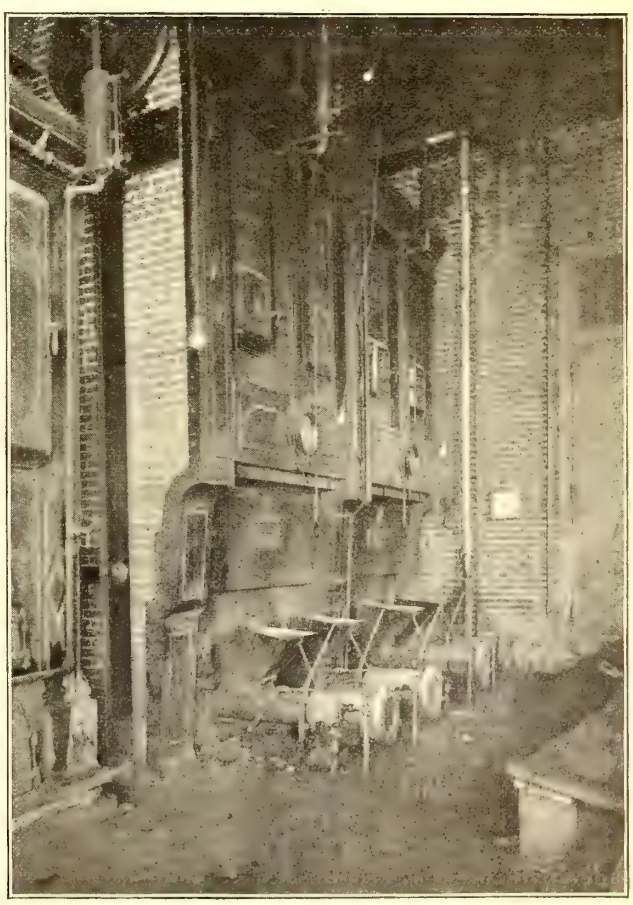
POWER STATIONS

The Detroit, Ann Arbor & Ypsilanti Railway, the longest line of the group, was put in operation last summer and takes its power from two stations, one at Dearborn, the other at Ypsilanti. The stations are identical, with the exception of the number of units in each, so that a description of the Dearborn station will suffice for that at Ypsilanti. The station is of brick, 73 ft. 6 ins. x 68 ft. 5 ins., divided into an engine room 71 ft. x 31 ft., and a boiler room 71 ft. x 35 ft. The former contains three 500-h.p. Westinghouse Kodak compound condensing units, with two boosters rated at 150 kw. each, but frequently carrying a very much higher load than this. The circuit breakers are set at 1150 amps., although the generators are rated at 392 amps. The switchboard is of the Westinghouse panel type, and a large Whiting crane runs the full length of the engine room. The gage board is of 2-in. marble, measures 4 ft. x 6 ft., and is particularly handsome. The floors are of concrete, laid with steel I-beams, with brick arches, making the station entirely fireproof. The boiler room is equipped with three batteries of 250 h.p., Babcock & Wilcox boilers, fitted with Roney mechanical stokers, which are giving excellent satisfaction. Mechanical draft is used, supplied by a duplicate set of 110-in. Detroit blowers belted to small Westinghouse Junior engines. An extra wheel is put on the stoker engine and is belted up to a shaft, by which the economizer scrapers are operated. The rest of the equipment of the boiler room includes Worthington compound duplex jet condensers, Baragwanath heaters, the Wefugo filters, and an American economizer. The feed water is first taken from the hot well, thence passes into the filter, thence to the heater, and thence to the economizers, from which point it is introduced into the boilers. The piping is extra heavy, on account of the high steam pressure used, viz., 175 lbs. to the inch. From the boilers the live steam passes by 6-in. w.i. header to a 10-in. w.i. main, from which it is fed by 8-in. pipes to the engines. The usual Westinghouse steam loop and separators are employed, and no elbows are used in the live steam piping, which is covered by Johns magnesia covering.

In the basement is a Worthington fire pump, 12 ins. x 7 ins. x 10 ins., with a capacity of 320 gals. per minute. This is also used for washing cars in the car barn, sprinkling the lawns, etc. Steam is always kept up in this pump, even when not in use, and it can be made to operate by the turning of a valve. The contractors for this station, as well as for all the electrical apparatus, were Westinghouse, Church, Kerr & Co.

The power station of the Lakeshore Railway Company

is at Lakeside, and has an entirely different equipment. It is of brick, 100 ft. x 40 ft., with metal roof, and contains two Russell compound 4-valve engines, guaranteed to develop 450 h.p. on 125 lbs. of steam, with an efficiency of 90 per cent when working at the most economical point of cut off; each engine directly connected to a 300 kw. Siemens & Halske generator. There is also a 200 h.p. Russell 4-valve engine directly connected to a 100 kw. Siemens & Halske booster. The switchboard is of the usual type. The boiler room contains two Stirling water tube boilers, each equipped with a Jones mechanical stoker. The room also contains a Laidlaw-Dunn-Gordon single-jet condenser for each engine, Wainwright closed feed water heater and the usual apliances.



ENGINE ROOM—DETROIT, LAKESHORE & MT. CLEMENS RAILWAY

On account of the great depth and mass of the coal in the stoker, forced draft was considered desirable. The pressure of air ranges from 1½ oz. to 5 oz. per sq. in., according to the steaming capacity of the boiler, and the quality of coal used. The quantity of air delivered at these pressures ranges from 6500 cu. ft. to 12,000 cu. ft. per minute, which is sufficient for a consumption of from 1600 lbs. to 3600 lbs. of coal per hour.

The blower used was made by the American Blower Company. The wheel is 34 ins. in diameter, and the discharge outlet 20 ins. in diameter. When running 830 r.p.m. this blower will produce 1½ oz. pressure, and at 1525 r.p.m. will produce a 5-oz. pressure, with an expenditure of about 2 per cent of the total output of steam from the boilers, for power to drive the blower when running at maximum speed. The blast piping runs along the front of the boilers over the fire doors with branches extending down between them and discharges into what is ordinarily the ash pit, but with these stokers it is an air chamber beneath the stokers. This piping is made of heavy galvanized iron, soldered and riveted to make it air tight. In each branch pipe from the main pipe is fitted a blast gate to control the volume of air delivered to each boiler, according to how the fire burns under each. The air finds egress through long narrow slits or openings in a row of tuyere blocks, running the entire length of the stokers. This brings the blast beneath the ignited coal and causes the fire to burn with equal force at the front, middle and back of fire-bed.

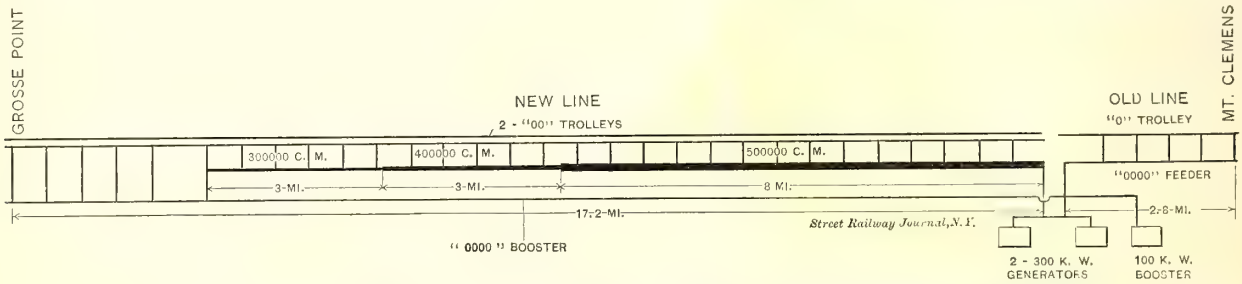
The well from which the feed water is taken holds 39,000 gals., and is fed by an 18-in. intake pipe from the lake and an overflow pipe of the same size from the engines. The station, with the car house adjoining it, was built by the Arbuckle-Ryan Company, of Toledo, under the supervision of the engineers of the company, Van De Mark & Hill. The road was financed by the International Construction Company, of Detroit.

The power station of the Detroit & Pontiac Railway is at Birmingham. It contains two Westinghouse compound condensing engines with Worthington pump and condenser, a Westinghouse generator belted to one engine and two Detroit generators belted to the other engine.

BOILER ROOM—LAKESHORE & MT. CLEMENS RAILWAY

The boilers are of the horizontal return tubular type with vertical open heaters and New York filter. The total power capacity of the station is 600 h.p.

The power station of the Wyandotte & Detroit River Railway is at Ecorce, and contains two 150 Dick & Church compound condensing engines, built by the Phœnix Iron Works, each belted to a Westinghouse 4-pole 100 kw. generator. The boilers are of the Manning vertical tubular type, with Conover condensers and closed heaters.



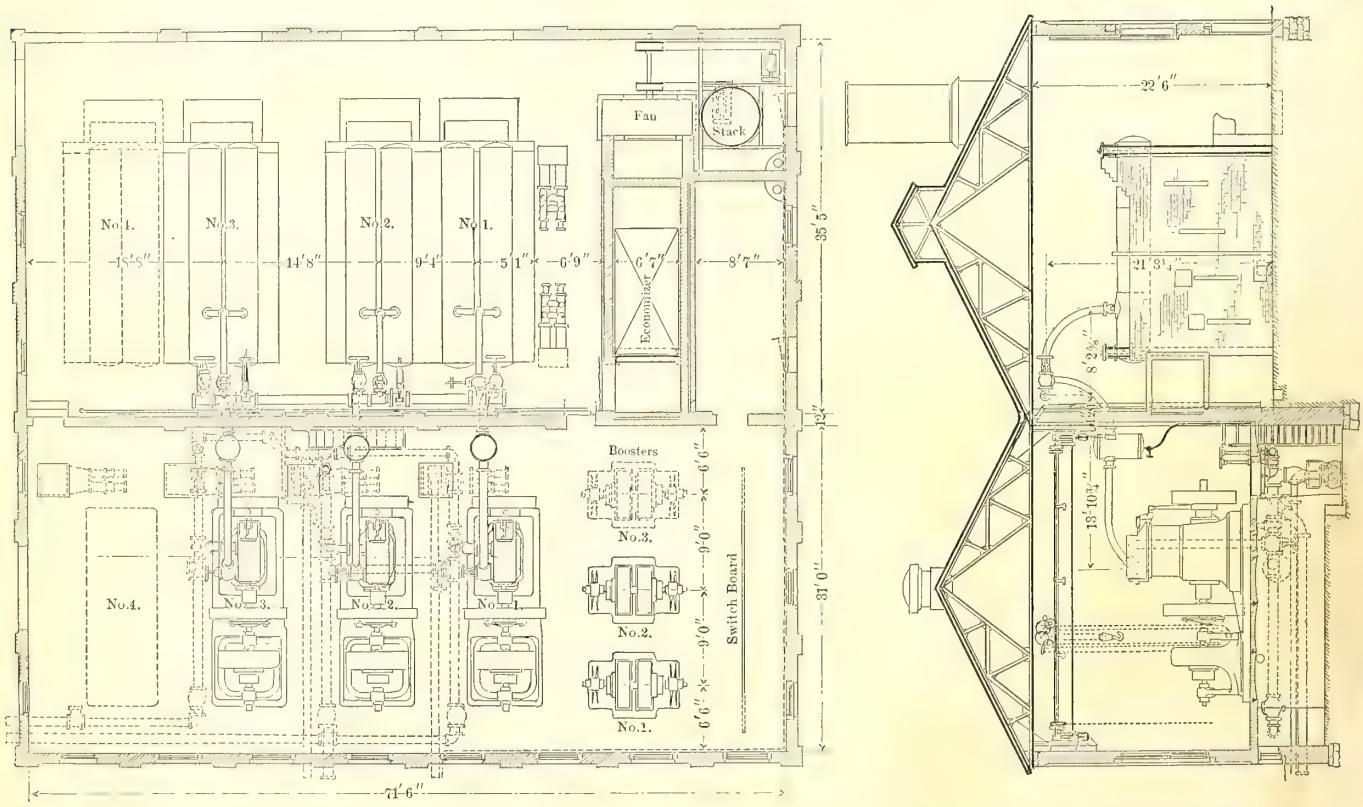


DIAGRAM OF FEEDER SYSTEM—DETROIT, LAKESHORE & MT. CLEMENS RAILWAY

The power station of the Rapid Railway contains two 250 kw. and one 400 kw. Walker generators, driven by Dick & Church engines. The boilers are of the horizontal tubular type.

The Grand River & Orchard Lake Railway power station is at Pontiac, and contains an American engine belted to a Walker generator.

OVERHEAD CONSTRUCTION

The overhead construction employed on all the roads is generally of the bracket type with flexible suspension. It is universal to use two trolley wires on all the single-track roads to avoid frogs, which have been found undesirable when running at high speeds. These trolley wires are connected together electrically at intervals of every five or ten poles, so that they reinforce each other and reduce by the amount of their cross sections the amount of feeder required. The two latest roads built employ No. 00 Fig. 8 trolley wire, equipped with Ohio Brass Company appliances. The poles are universally wooden and the specifications for those on the Lakeshore Railway, which are good samples of those employed, require that they shall be from 30 ft. to 35 ft. in length, depending upon whether they are side poles or curve poles, 7 ins. in diameter at the top, of cedar, and set one-sixth of their length in the ground. The poles have all rock setting, are spaced 115 ft. apart, and are 6 ft. 9 ins. from the center of the track. On the Pontiac and the Wyandotte lines every pole is numbered by miles; thus, those in the first mile are numbered from 0 to 42 or 43, in the next mile from 100 to 142, etc. The Wyandotte line was originally equipped with rigid brackets, but they were found undesirable for this service, as the wire would break at the hanger. On these two lines, which were for a long time under the same management and which are among the oldest of the interurban lines, pine, hemlock and cedar poles have all been used, and but little difference has been found in their life, each kind having to be replaced at the end of six years. The Lakeshore Railway is employing bare feeder wires and its feeder system is shown diagrammatically above. This distribution is based on a service of six cars, each of which takes on an average about 150 amps. when running at 30 miles per hour on a level.

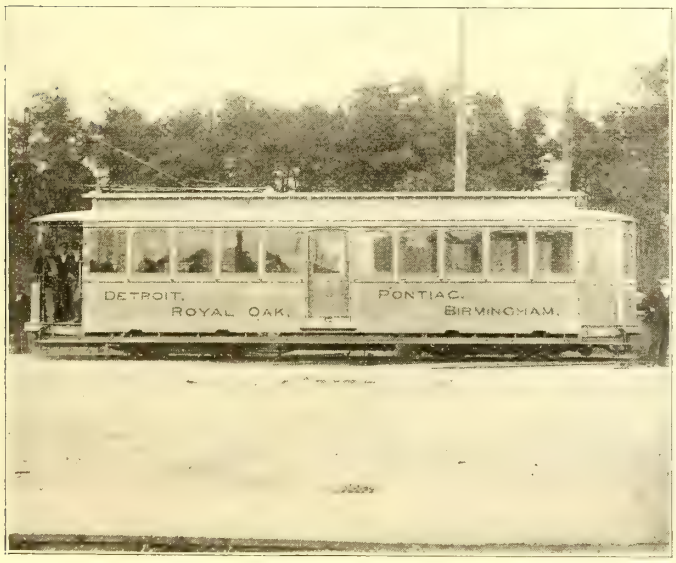
PLAN AND SECTION OF POWER STATION—DETROIT, YPSILANTI & ANN ARBOR RAILWAY

Quite a little difference exists in the use of trolley wheels. The Lakeshore cars are fitted with two trolleys, one immediately in the rear of the other, but the two are used only in the case of heavy loads. The wheel has a diameter

of 6 ins., with a groove 2 ins. in width and flange 1¼ ins. in height. Wilson-Thompson trolley pole catchers are employed on this line. Practically all the lines employ the Kalamazoo trolley wheel, the hub of which is hollow and contains oil, providing excellent lubriction. This wheel

VIEW ON PONTIAC RAILWAY SHOWING TRACKS AT SIDE OF HIGHWAY

seems to answer well the requirements of high-speed service.



Practically all of the lines maintain a telephone service throughout the entire line. Every car carries a telephone and connection can be made with the telephone wires at turnouts by means of junction boxes. If the conductor should desire to send a message between turnouts, he makes connection with the telephone wires by means of a flexible connection, and jointed poles furnished with hooks are hooked over the telephone wires.

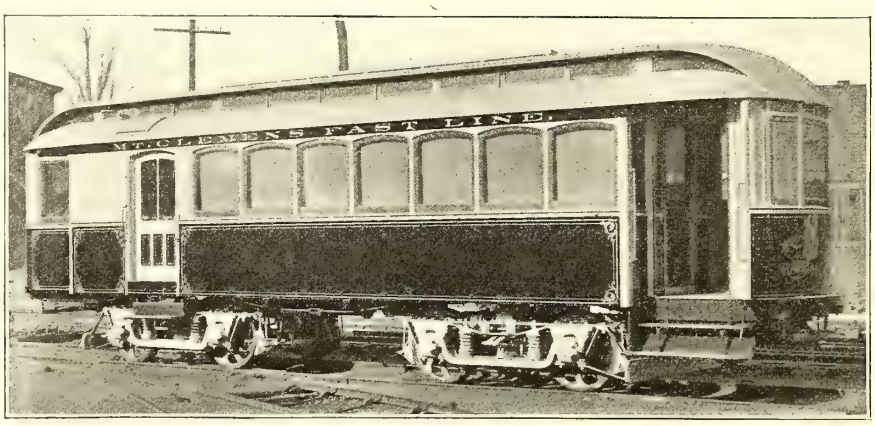
TRACK CONSTRUCTION

The T-rail is used throughout and the section of the American Society of Civil Engineers is popular. The rails weigh from 70 lbs. to 75 lbs. per yard on the lines lately equipped. On the earlier lines they are from 56 lbs. to 60 lbs. The ties are usually steam railroad standard, 6 ins. x 8 ins. x 8 ft., and spaced 2 ft. centers. The ties are usually set in gravel, and where the rail is carried through the towns, the side is packed with gravel. The Ypsilanti & Ann Arbor road and the Lakeshore road employ Forest City protected bonds; Washburn & Moen bonds are used on the Pontiac line. On the Lakeshore line American rail joints are used throughout; on the road, the special work was supplied by the Cleveland Frog & Crossing Company.

ROLLING STOCK

The tendency in rolling stock on the interurban roads around Detroit is unquestionably toward long, heavy cars. On the Lakeshore Railway they reach a maximum in being 50 ft. 6 ins. over all. This line has six motor cars and four trail cars, and will place an order for ten more cars for spring business. The Detroit, Ypsilanti & Ann Arbor Railway has fourteen long cars in use on its interurban line and twenty short cars belonging to the old Ann Arbor & Ypsilanti Railway and in use on the city lines in that city. The interurban cars on this railway and on the Lakeshore Railway were built by the Barney & Smith Company. The Rapid Railway has seventeen 42-ft. cars, supplied by

EXTERIOR AND INTERIOR OF DETROIT & PONTIAC CAR

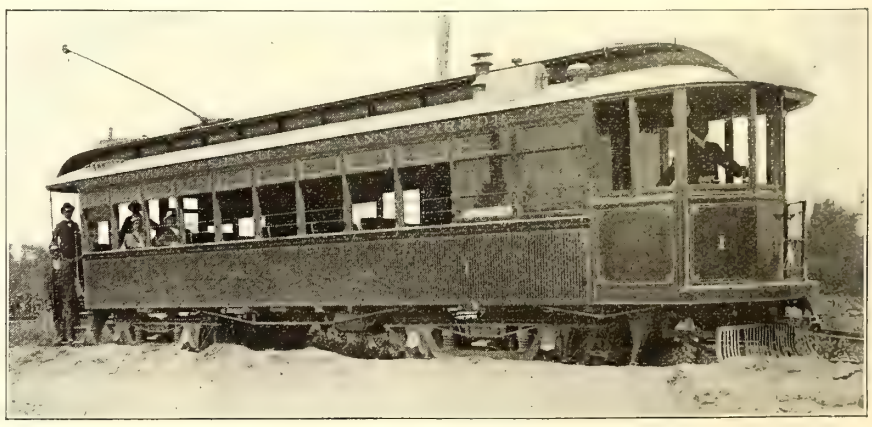


the Barney & Smith Company; one 47-ft. and eight 32-ft. cars, built by the Jackson & Sharp Company. In addition, it has sixteen freight cars, all trail cars. The Detroit & Pontiac Railway has twelve Kuhlman cars, 42 ft. over all, for passenger service. The Wyandotte & Detroit River Railway is equipped with Jackson & Sharp single-truck cars measuring 30 ft. over all. The Grand River Railroad has on its Grand River section five motor cars and four trail cars, built by the Brill Company and the Wells-French Company. The Detroit & River St. Clair Railway, being equipped at present with standard steam equipment, will not be considered in this connection.

The number of miles run per day by each car on the different electric roads averages about 300. All the recently

LAKESHORE CAR

built cars are similar in appearance to steam railroad cars, and have straight sides. Views of a number of these cars are given herewith. Those on the Lakeshore will attract attention as being the most novel in floor-plan and general arrangement. Each car contains a baggage and smoking compartment, which is fitted with foldable seats; a state-room, containing four seats, which are rented for the trip for ten cents additional fare; complete toilet, water cooler, etc., besides regular passenger compartment seating about fifty passengers. These cars are lighted with twenty-five 16-c.p. lamps each, and carry a Wagenhall's electric headlight. The weight of these cars without electrical equipment is: body, 25,320 lbs.; truck, 13,140 lbs.; total, 38,460 lbs. The state-room idea is a novel one in electric railroading, and has proved extremely popular with the patrons of the line; it is often rented to a party of four commuters, who wish to play cards on the trip, or who desire special seclusion. The weight of the convertible on the same line is: body, 18,600 lbs.; trucks, 12,600 lbs.; total, 31,200 lbs. The floor plans of these cars give full information as to dimensions.

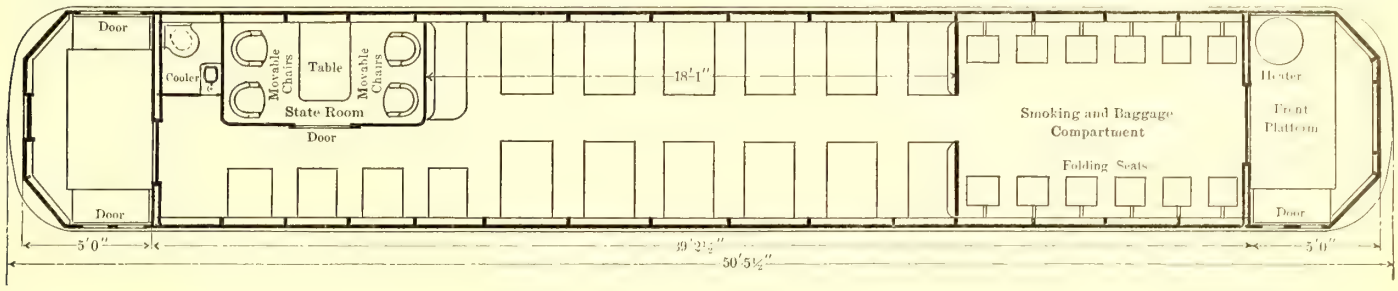


RAPID RAILWAY CAR

The Detroit, Ypsilanti & Ann Arbor cars were also built by the Barney & Smith Company, and are very complete. They are of two types, one of which is illustrated. Both are equipped with combination baggage and smoking compartments, toilet, etc. The long car weighs: body, 25,500 lbs.; trucks, 13,600 lbs.; total, 38,100 lbs. The shorter car weighs: body, 22,900 lbs.; trucks, 13,600 lbs.; total, 36,500 lbs. The trail cars on this line weigh: body, 20,500 lbs.; trucks, 13,600 lbs.; total, 34,100 lbs.; all without electrical and air-brake equipment. An interesting feature of these cars is the novel arrangement of the vestibule. Owing to the length of these cars the passengers are allowed to enter and leave the car at either end, and to prevent their passing through the motorman's compartment, the front of platform is only half vestibuled. On some of the cars which the company is proposing to install, the center of the front platform only will be vestibuled, leaving exits on each side for passengers without entering the motorman's compartment.

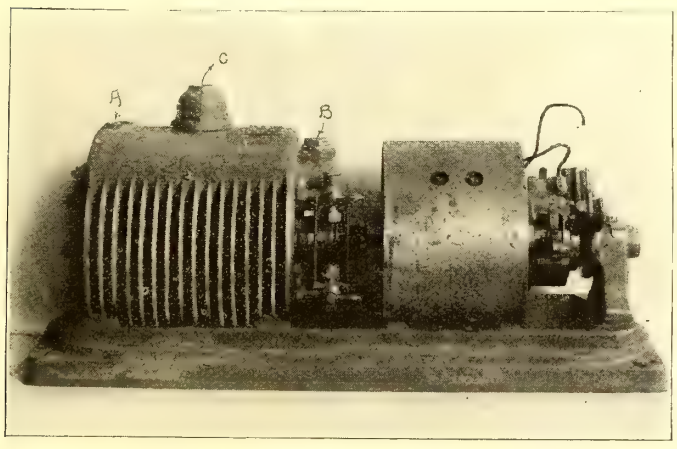
The Detroit & Pontiac cars, which are also illustrated, were built by the G. C. Kuhlman Company, with a side aisle on what is commonly known as the Kuhlman pattern, and a number of them are fitted with baggage and smoking compartments. They measure inside 33 ft., and over all 42 ft. One characteristic of these cars, besides their extremely handsome appearance, is that they are very low, in spite of the fact that 33-in. wheels are used. This result is accomplished by making the wheels swing inside the side sills of the car.

The Rapid Railway cars, built by the Jackson & Sharp Company, also deserve special mention. The motor cars are of two lengths, one with 24-ft. body and 32 ft. over all, finished in cherry, with cross seats upholstered and rattaned, and a passenger and baggage car with 37-ft. body and 47 ft. over platforms, finished in quartered oak. The Jackson & Sharp Company also supplied this company



YPSILANTI & ANN ARBOR CAR

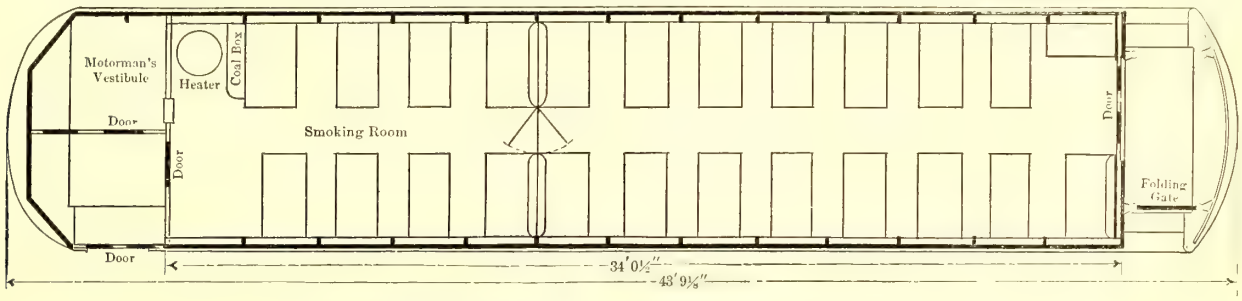
with eight ten-bench open trail cars, with six reversible and four permanent seats, finished inside with white ash, with cherry moulding and white birch veneer ceilings.



The motorman's vestibule in all these cars contains quite a variety of apparatus. A list of these as carried on the Lakeshore cars, which are a good sample of all, includes

a long-distance telephone, with flexible connections, for communicating with the central office from any point of the line; a G. E. circuit breaker, the Christensen airbrake controller with gage, fuse-box and automatic controller for the motor compressor; sand-box, bell, handbrake, and hot-water heater, besides the regular motor controller and appliances.

PLAN OF DETROIT, LAKESHORE & MT. CLEMENS CAR



The heaters employed are generally of the hot-water type, Baker heaters being the most generally used. These heaters are of the "Mighty Midget" type, in which the heater is carried on the front platform, and the interior of the car is warmed by hot-water pipes fed from it. The heater occupies but little room on the platform, and is cared for entirely by the motorman. Full particulars of this heater are given elsewhere in this issue, and it seems to be giving excellent satisfaction. On the Lakeshore and on the Pontiac cars the heater is carried on the front platform; in the Ann Arbor cars, in a closet in the regular passenger compartment.

MOTOR COMPRESSOR

AIR BRAKES

There is a wide divergence in the practice in the use of air brakes, four different kinds being in use. The Detroit, Ypsilanti & Ann Arbor Railway employs the Westinghouse airbrake with automatically controlled electric motor and compressor, this being the first application of this system to any electric road. The general diagram of the arrangement of the system, together with a view of the motor and compressor directly connected and mounted on a single base, is given on this page. The compressor is of the rotary type, and the cast iron housing in which it is placed forms an oil reservoir, the upper portion of which is a suction chamber. The ribbed construction of the housing is for providing greater cooling surface for the compressor. The course of the air is from inlet *A* to the suction chamber, thence through a valve suitably arranged at *B* for allowing the air to pass into the pump and out at either of the reservoirs. The compression is effected in two separate cylinders, one for high pressure, and the other for low pressure.

PLAN OF DETROIT, YPSILANTI & ANN ARBOR CAR

The Pontiac Railway employs the Magann air brake, in which no compressor of any kind is in use on the car, but the air is stored to a pressure of about 225 lbs. in reservoirs carried on the car. These reservoirs are connected through a reducing valve with a working reservoir of about 40 lbs. pressure, from which the jam cylinder is operated. The compressor for storing the reservoirs on the cars is located at the power station, in Birmingham. Connection is made by a flexible coupling, the cars are stored and disconnected from the coupling in less than half a minute.

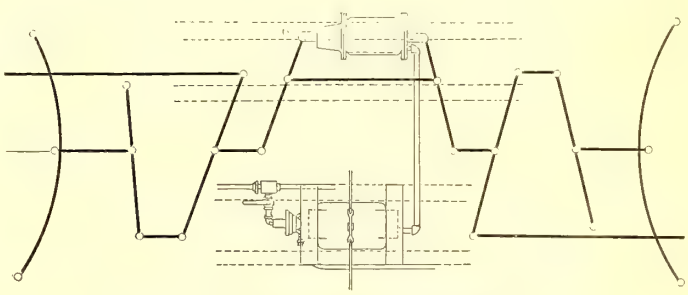


DIAGRAM OF AIR BRAKE EQUIPMENT

Full particulars of this air brake are given elsewhere in this issue.

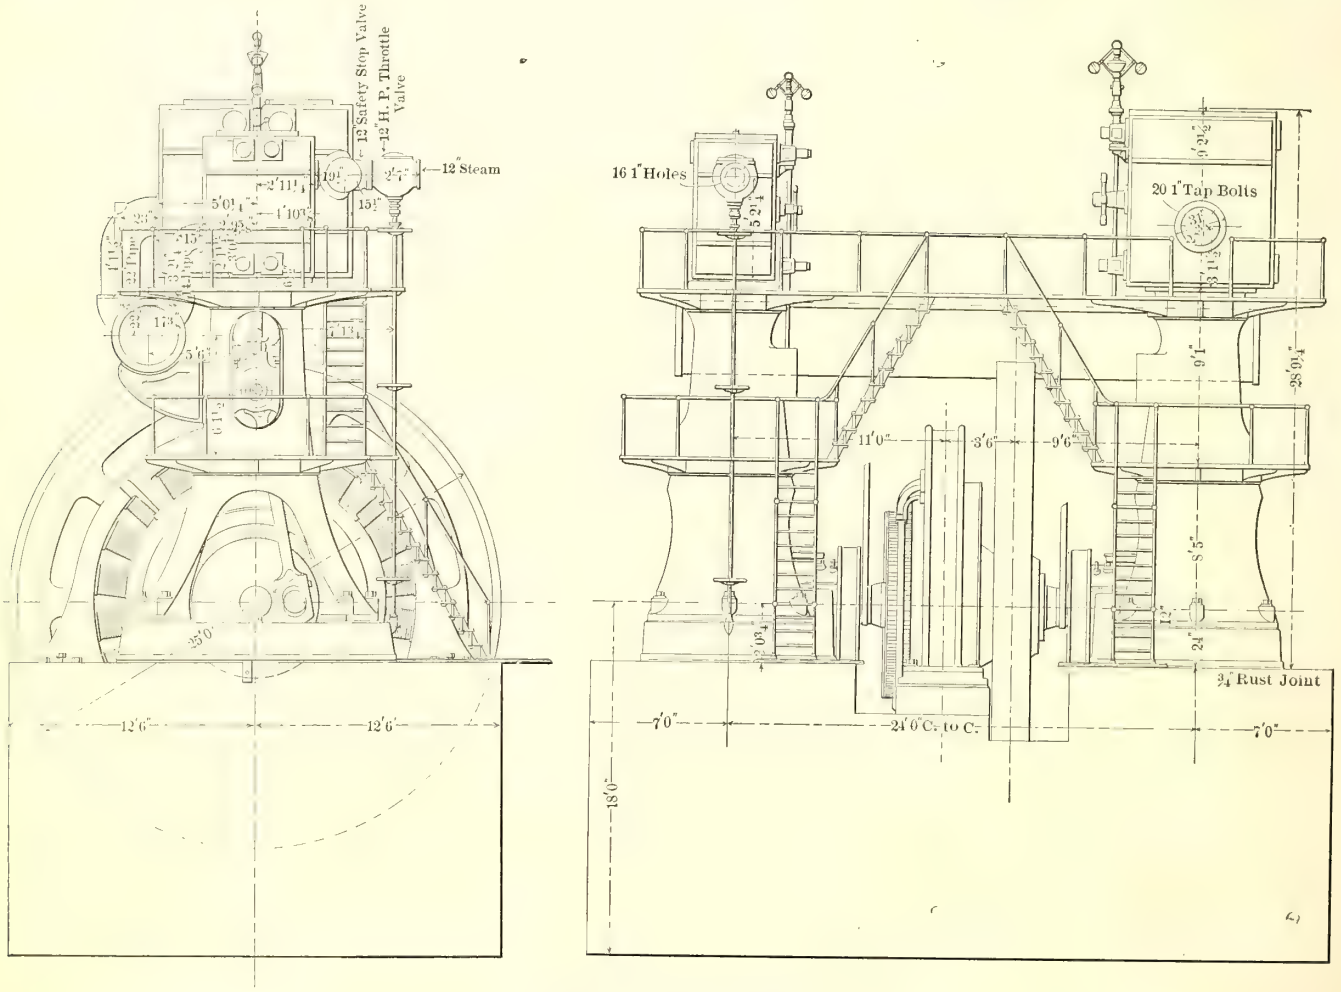
The Lakeshore cars are equipped with the Christensen air brake, with motor compressor, which is carried under the car between the trucks. This system is working very satisfactorily.

On the Rapid Railway twelve of the cars are equipped with Hunt air brakes, with motor compressors, and two with Sellers, Beamer & Nauger air brakes, with compressors of the axle driven type with automatic cut-outs. Both are reported to be giving satisfaction.

MISCELLANEOUS CAR EQUIPMENT

The car wheels are usually of the plate type and vary from 500 lbs. to 350 lbs. each, depending upon the weight of the car. On the Pontiac Railway a spoke wheel weighing 480 lbs. is employed, the management of this line thinking that these wheels are more noiseless than the plate wheels.

Brill 27 trucks are used on the Pontiac line, Barney & Smith trucks on the Ypsilanti and Lakeshore lines, Du Pont trucks on the Wyandotte lines, and Barney & Smith and Jackson & Sharp trucks on the Rapid Railway.



The Ann Arbor & Ypsilanti and Lakeshore lines use four motors for each car, the type employed being 50-h.p. Westinghouse, with Westinghouse 4-motor controller. The Pontiac line (double-truck cars 42 ft. over all) and the Wyandotte line (single-truck cars 32 ft. over all) use two motors on each car. On the Pontiac line the two motors are carried on the rear truck, the bolster of which is set 1 ft. nearer the center of the car than is the bolster on the front truck. The motors on the first line are mostly Steel motors, that on the latter Westinghouse No. 3, with old type resistance controllers. The Rapid Railway employs both practices on its long 42-ft. cars. The motors are mostly of the Walker type, and the general manager states that he finds two 75-h.p. motors more desirable than four 50-h.p. motors, and as easy to obtain traction with them. On this road, where two motors are employed, a motor is carried on the rear axle of each truck.

Our experience has been that if the conductors and the passengers will use the transfers as we intended they should use them, we can afford to give them.—From address at the Montreal Convention, 1895.

Large Engine for Louisville

The accompanying illustration shows side and end elevations of one of the largest engines, if not the largest, yet built for electric railway service. It is a vertical compound, with cylinders 40 ins. and 78 ins. x 48 ins. stroke, and was constructed for the Louisville Railway Company of Louisville, Ky., by the E. P. Allis Company. It is direct connected to a 1600 kw. General Electric generator, and the large size of cylinders was necessary on account of the low steam pressure used, about 100 lbs.

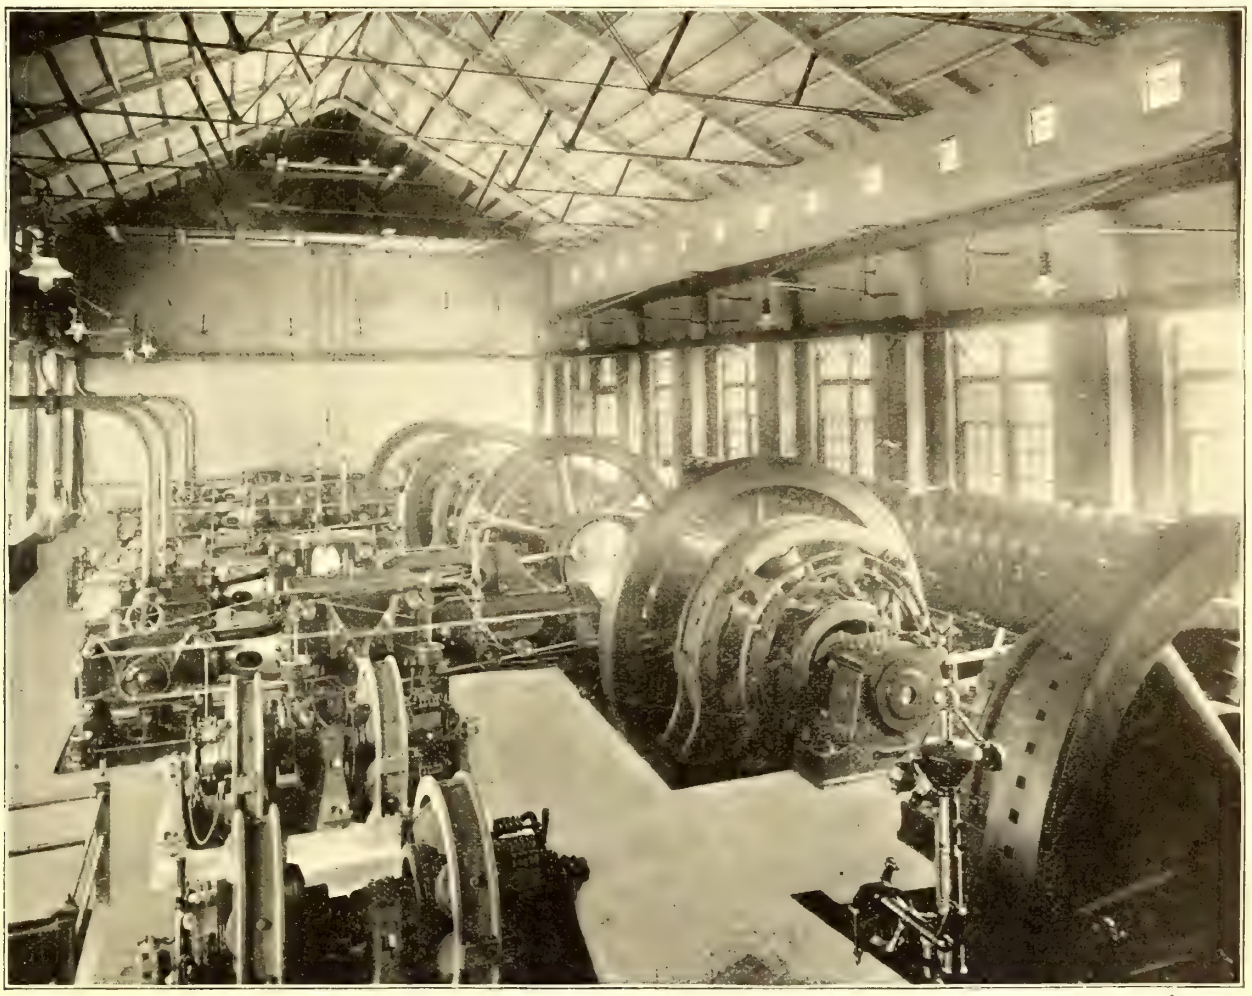
The main shaft of the engine is solid, and is 27 ins. in diameter. The fly wheel is 25 ft. in diameter, and weighs 160,000 lbs. The journals are 24 ins. x 48 ins. The crank pin is 12 ins. x 12 ins. The normal speed is 75 r.p.m. The valve gear is of the regular Allis-Corliss type. The engine is fitted with two governors, one for ordinary running and one for operating the safety stop valve, which becomes operative when the speed exceeds the normal by five revolutions. The total weight of the engine is 325 tons.

LARGE ENGINE FOR LOUISVILLE

The engine illustrates the current favor with which vertical engines for large units are regarded. The chief advantages claimed for this type are the reduction in wear, less chance of cylinder cutting, and less lubrication. The limiting size, according to present practice for horizontal engines, seems to be in the neighborhood of 50 ins., cylinder diameter. The saving in floor space is also an important item. For the same capacity as the engine illustrated a horizontal engine would have to be of the same width, but 40 ft. length instead of 25 ft.

The engines being built by the Allis Company for the Metropolitan Street Railway Company, of New York, are also of the vertical type.

The New Power Station of The Capital Traction Co., Washington, D. C.



On Sept. 29, 1897, the power house of the Capital Traction Company, on Pennsylvania Avenue, Washington, D. C., was destroyed by fire, and the system which, up to that time, had been driven entirely by cable, was brought to a complete standstill. Traffic was resumed temporarily by means of horse cars, and the contrast between the modern system in use on other roads and the antiquated method which the Capital Traction Company was compelled to employ on Washington's streets at that time, emphasized distinctly the tremendous progress made in city transportation during the last decade.

In re-equipping the road the use of the trolley was prohibited by the municipal laws, so that choice lay between the electrical underground conduit system and cable. The former was adopted, and full particulars of the method of converting the existing cable conduit to one suitable for electric use was fully described in the STREET RAILWAY JOURNAL for January, 1898. Since that time the power station of the company has been completed, and is distributing power not only to the main lines of the company on Pennsylvania Avenue and Seventh Street, but also to the suburban lines using the trolley system.

The company was fortunate in possessing a location for its power house most conveniently situated for the purpose. On the banks of the Chesapeake and Ohio Canal it owned an old warehouse, one side facing on the canal, the other on Grace Street, between Thirty-second and Potomac Streets. This it practically rebuilt.

The present power house is 300 ft. long x 60 ft. wide and 65 ft. high, and is divided into two parts by a heavy brick partition wall, the eastern end being occupied by the engines and dynamos, and the western end by the boilers. West of the main building is the coal handling building. Facing the power house on the other side of the canal is a large car barn and repair and machine shop.

The boiler room, 162 ft. 9½ ins. long, contains eight Cahall, Babcock & Wilcox boilers of 350-h.p. capacity each, arranged in four batteries. The flues pass into a steel brick-lined stack of 9 ft. internal diameter and 150 ft. high, standing on a 25-ft. brick base, giving it a total height of 175 ft. The stack was built by the Campbell & Zell Company, and is provided with Locke regulators and dampers. The boilers are equipped with Roney mechanical stokers, built by Westinghouse, Church, Kerr & Company, and driven by three small Westinghouse engines, two driving the stokers for the three main batteries, and one those of the battery made up of the boilers on the west side of the stack.

INTERIOR OF POWER STATION CAPITAL TRACTION CO., WASHINGTON

The coal is taken directly from the canal barges on the Chesapeake and Ohio Canal by coal handling machinery furnished by the Steel Cable Engineering Company, of Boston, and operated by electric motors. It is housed in a small steel structure forming the western annex to the main building. A 30-h.p. motor operates a tub elevator, which raises the coal from the canal boats and dumps it into a receiving hopper, whence it passes to a weighing hopper with a capacity of 2000 lbs. on a Fairbanks scales. After weighing it drops through a chute into a crusher driven by the same motor. After crushing, the coal drops into the conveyor, which is driven by a 15-h.p. motor. The conveyor carries it up and dumps it into the coal bins over

the boilers. The returning buckets pass down the eastern side of the boiler room and through a tunnel below the boilers, where they catch the ashes from the ash hoppers and bring them out on the return journey, dumping them into an ash tank, from which they are transferred to other canal boats or to carts to be carried away. The capacity of the conveyor is 30 tons per hour. The coal used is "run of mine" Cumberland. The coal bins are duplicate bins, built of steel, and occupy the entire space above the boilers, or 162 ft. 9½ ins. x 60 ft. The bins are lined with concrete on corrugated iron arch plates. They were built by the Structural Iron Company, and have a capacity of 2000 tons. The coal is delivered into the furnaces of the boilers through measuring hoppers, each having a capacity of 1000 lbs. The coal from the rear or auxiliary bins can be chuted down through three supplementary chutes set between the boilers to the conveyer in the ash tunnel, and can then be carried up again and dumped into the forward or main bin.

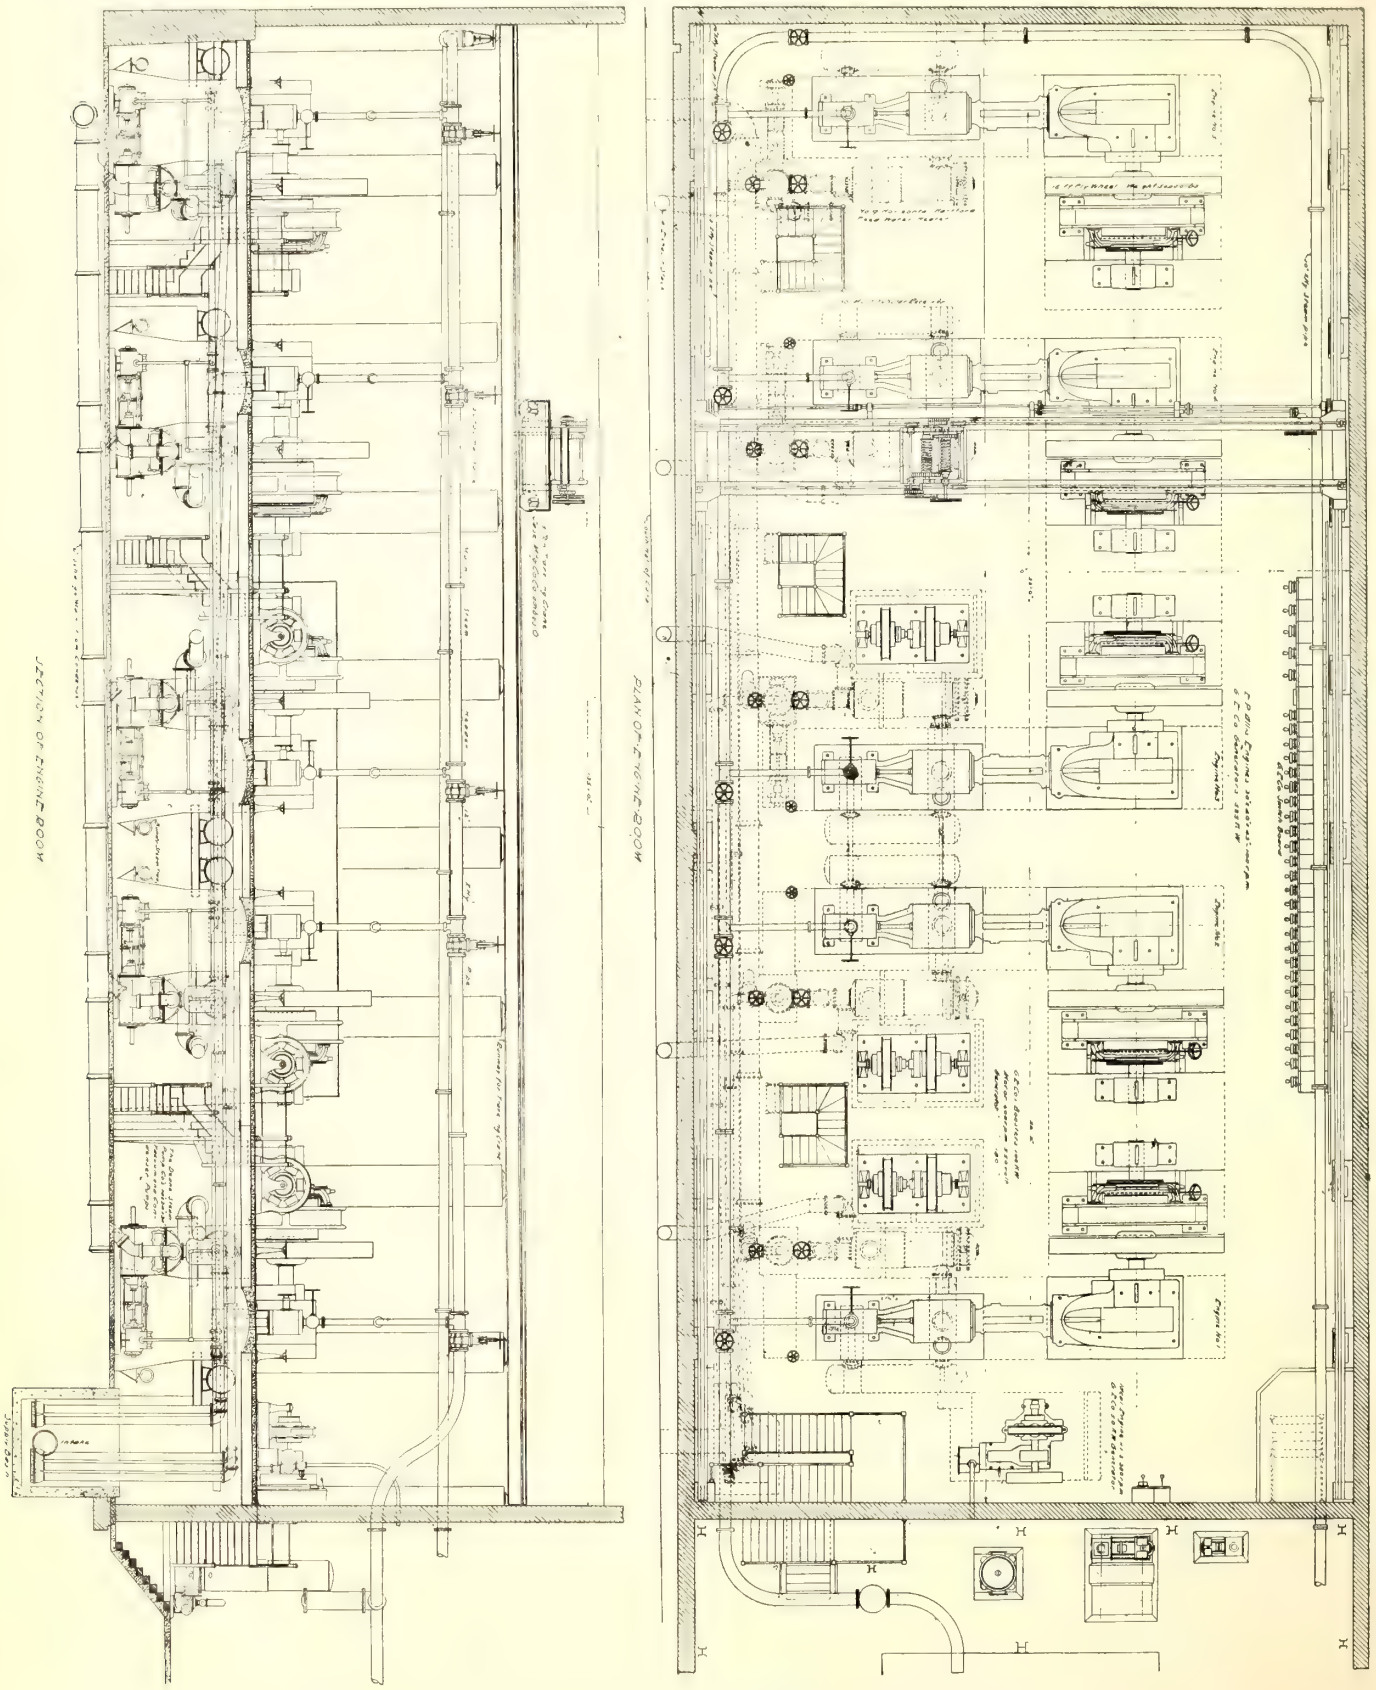


FIG. 1.—PLAN AND SECTION OF ENGINE ROOM—CAPITAL TRACTION CO.

Water for the boilers is pumped from a well in the base-

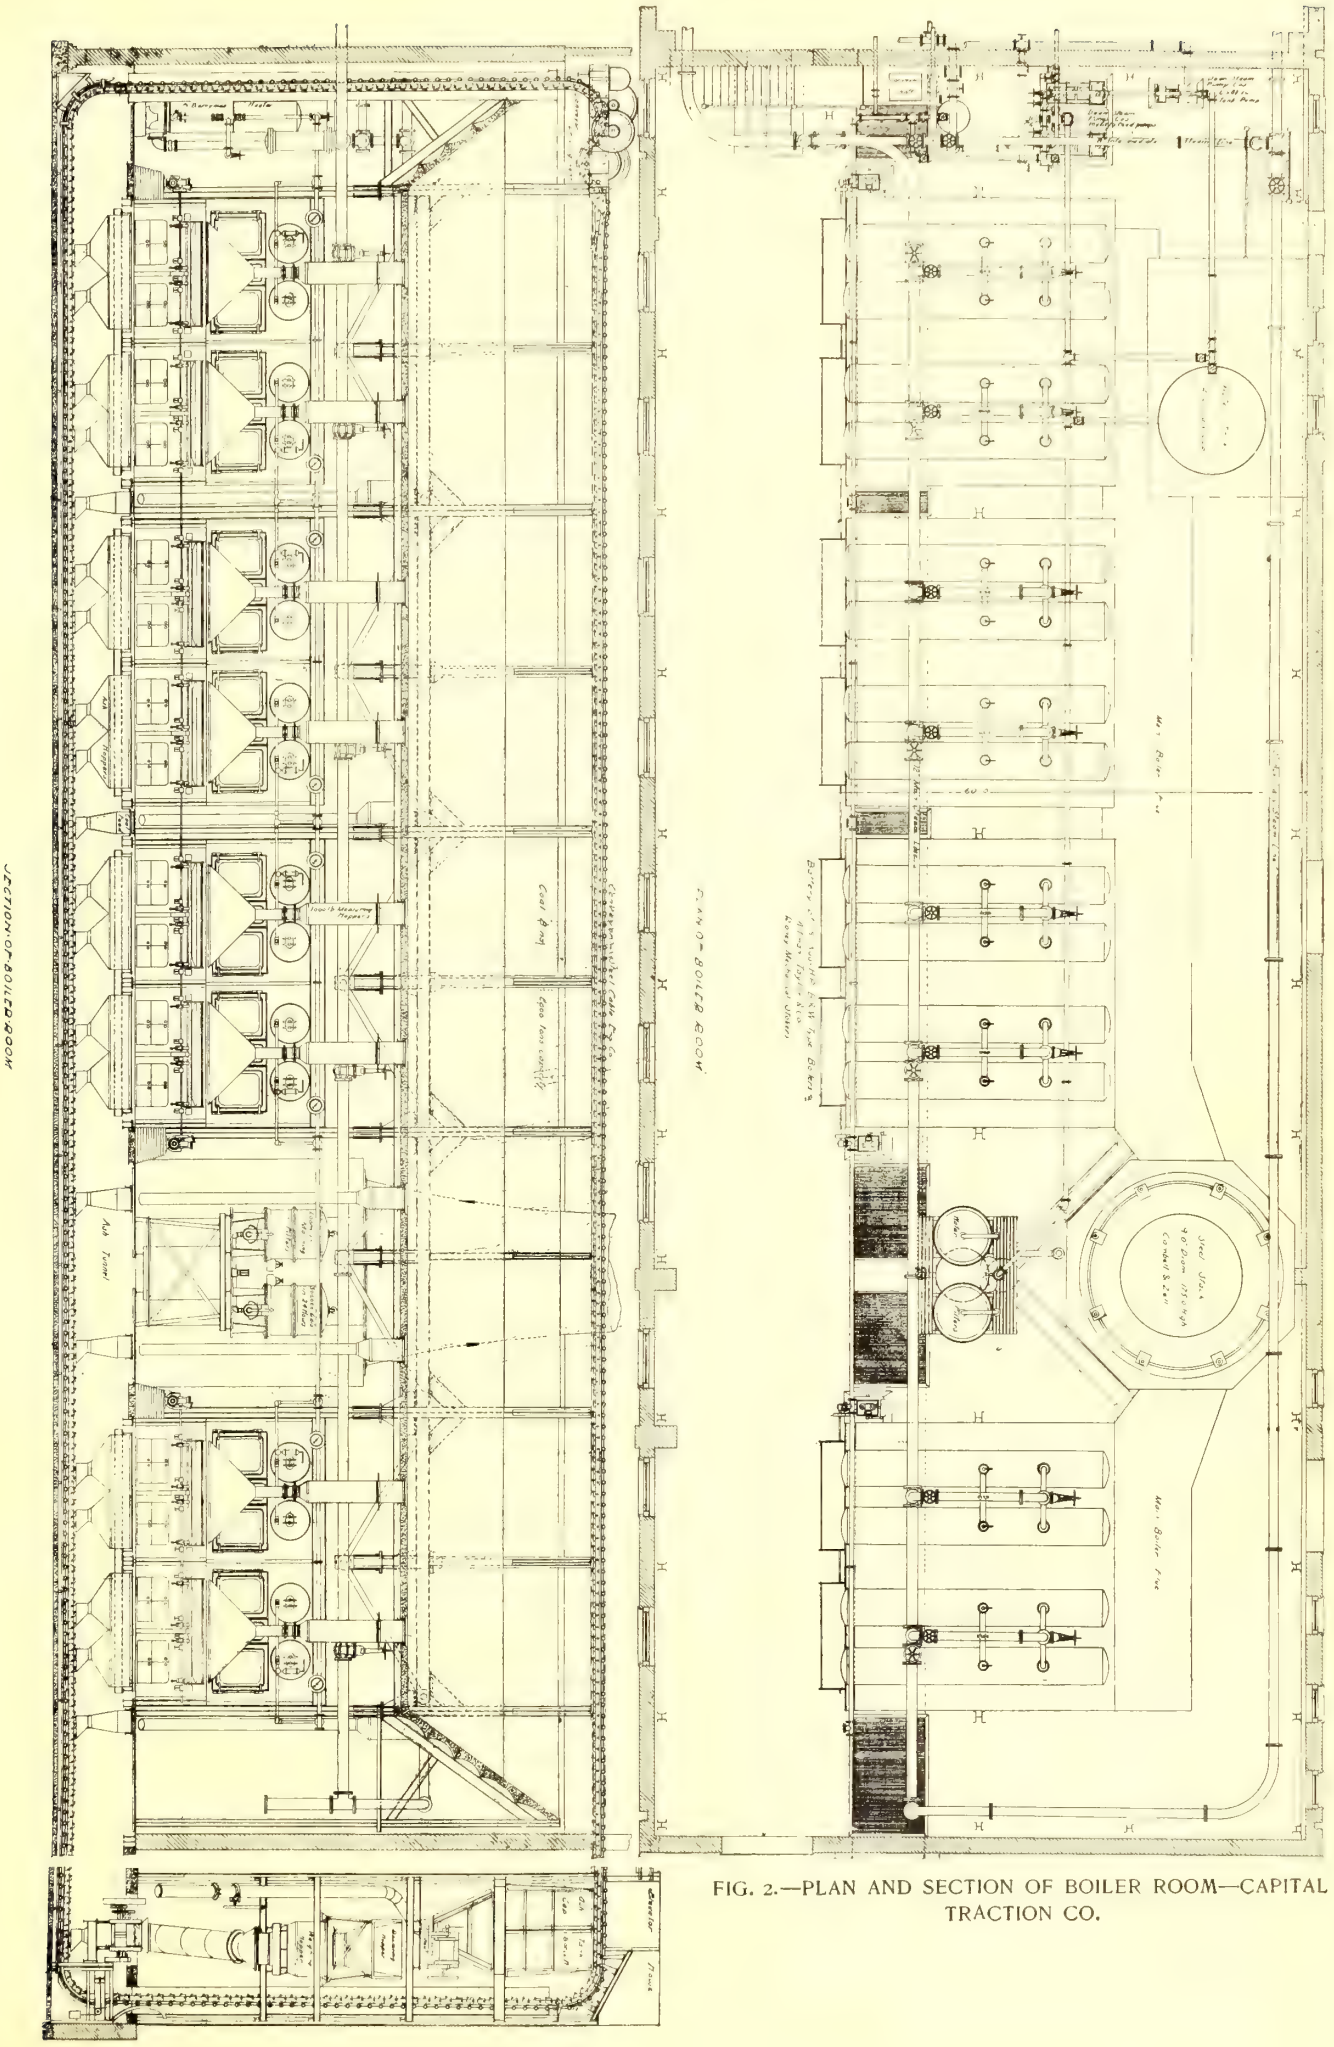

FIG. 2.—PLAN AND SECTION OF BOILER ROOM—CAPITAL TRACTION CO.

ment of the engine room, supplied from the canal, into a 4000-gal. tank, from which it passes into two Loomis-Manning filters having a capacity of 300,000 gals. in twenty-four hours, thence through Deane feed pumps to the primary heaters, then into a supplementary Berryman heater, and thence to the boilers. Water can also be taken from the city mains. After entering the main tank its course is similar to that of the canal water. Should the main feed lines or pumps break down from any cause, two Metropolitan injectors can be brought immediately into action on the auxiliary feed lines.

The arrangement of the piping above the boilers allows any battery to be cut out at any time, and, in fact, the entire arrangement of the piping and valves is such that any engine or boiler or any length of pipe can be cut out should occasion require without interfering with the running of the plant. The piping is in duplicate and extra heavy in both pipe and fittings. The valves are all of the Chapman Valve Company's make. All are constructed for a pressure of 200 lbs., although the initial steam pressure is at present only 140 lbs. The duplicate or auxiliary piping is arranged as a loop running from the main header in front of the boilers along the western, southern and eastern walls and joining the main steam line again on the north wall. At the eastern end of the boiler room connection from side to side of the loop is made by an intermediate pipe. The main steam line is of 12-in. pipe, the auxiliary of 10-in. pipe, and the intermediate steam line of 8-in. pipe. At the two points where the intermediate pipe joins the main and auxiliary piping a steam separator is provided. All piping is protected by Keasbey & Mattison magnobestos covering 2 ins. thick.

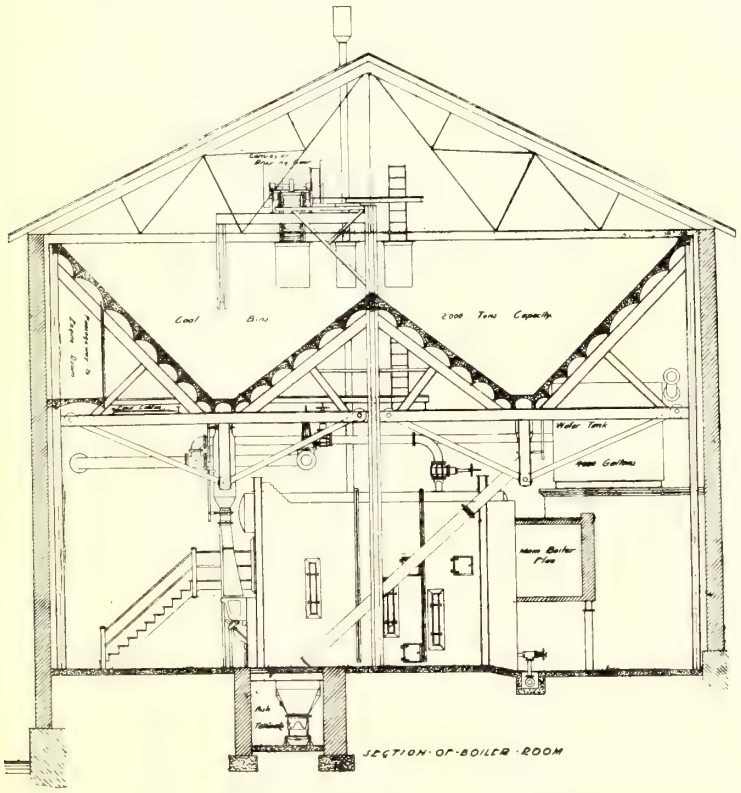

FIG. 3.—CROSS SECTION OF BOILER ROOM

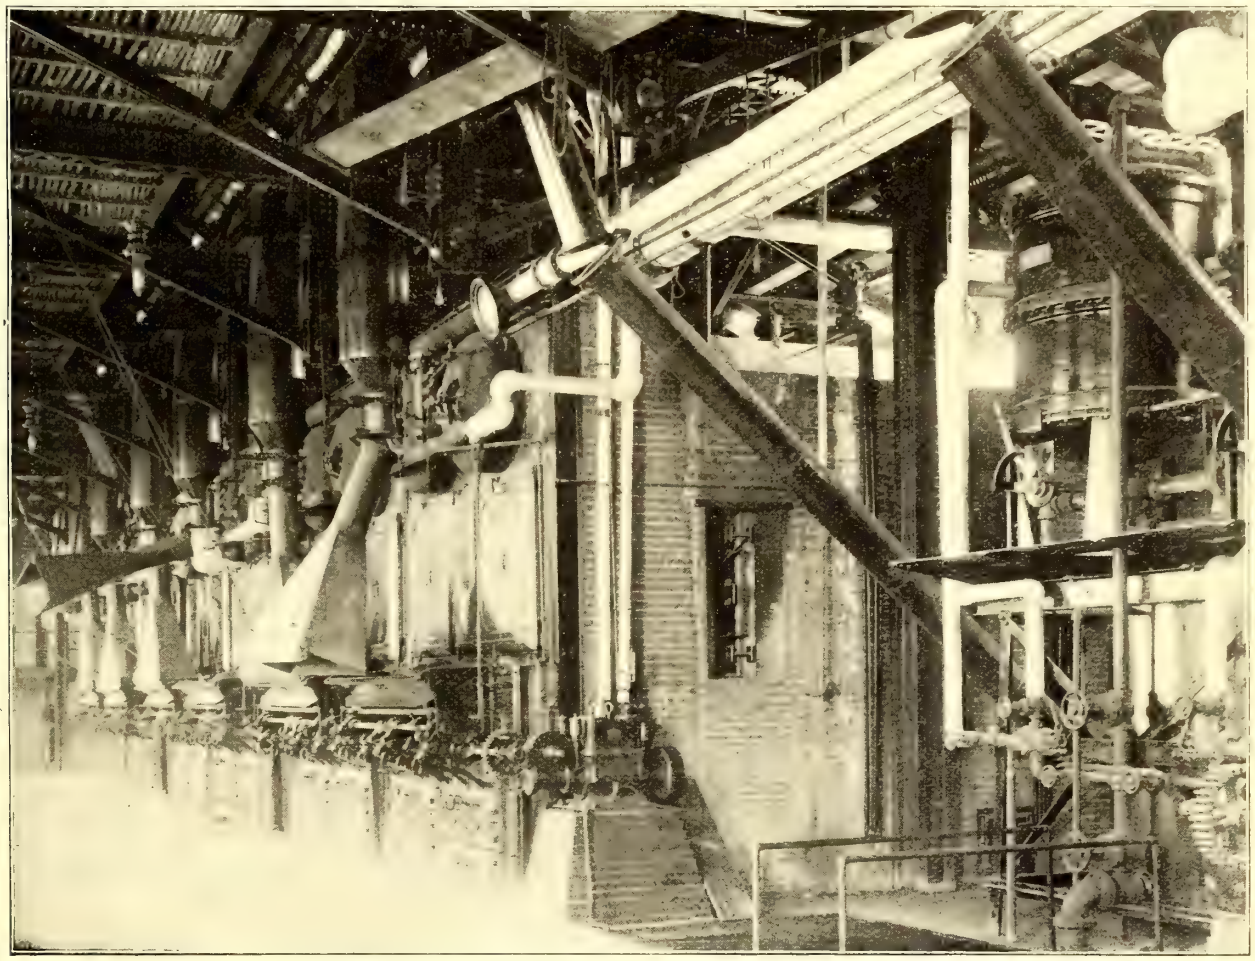
Behind the boilers space has been left for the installation of economizers should their use be decided upon. Behind the boilers also have been fitted up a bath-room for the engineer and lavatories for the men.

The engines, of which there are five, are Allis horizontal tandem compounds with 1890 frame, each 20 ins. and 40 ins. x 42 ins., rated at 800 nominal h.p. at 100 r.p.m. They are provided with double-ported valves and double eccentrics, and the ball governors have a safety attachment which automatically shuts the steam off from the cylinder in case the governor belt should break. Each fly-wheel is 16 ft. in diameter and weighs 50,000 lbs. The engines can be run condensing or free exhaust. Each engine is an entirely separate unit with primary feed water heater, receiver, condenser and separate free exhaust. The receivers are each 30 ins. inside diameter and 12 ft. 6 ins. long. The condensers are the jet type, built by the Deane Steam Pump Company, and the condenser valves are controlled by valve standards on the engine-room floor. In the event of accident to the condensing apparatus an automatic action opens the valve from the engine into the free exhaust pipe, through which the steam passes to the open air. Bundy steam traps are provided—one to each receiver, and one to the main steam lines. All the gages and instruments are of Crosby make.

Lubrication of the engine cylinders is effected from two pressure oil tanks in the basement, the oil being forced up by steam pressure through brass pipes to the cylinders. A third tank supplies the oil for the boiler-room pumps and engines. Ashton sight feed lubricators enable the engineer to gage the supply of oil as desired. Lubrication of the bearings is effected by a gravity system, the oil descending from a 50-barrel tank on the east wall, whither it is pumped up again after use, after first passing through filters.

The generators are directly connected to the engine shafts, and four are set in pairs, each pair facing each other; that is, with the two commutators on the inside. The commutator of the fifth faces engine No. 4. The generators are set in a line down the south side of the engine room, and are faced by the switchboard on the south wall. They are of the standard General Electric eight-pole, 525-kw. type, running at 100 r.p.m. and delivering current at 550 volts no load, and 600 volts full load.



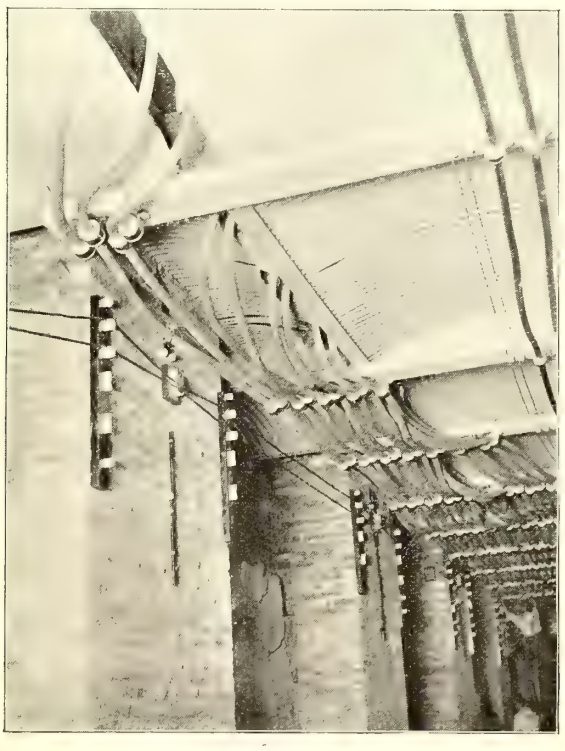
In order to compensate for drop on the Mt. Pleasant and Navy Yard lines—4 miles long in the first case and 5 in the latter—three boosters have been provided, two between engines one and two and one between engines three and four. These boosters are generators series wound for a maximum load of 550 amps. at 180 volts, and so proportioned as to give practically a straight line from zero potential to 100 volts. They are six-pole machines, each of 100-kw. capacity, running at 600 revolutions, and were supplied by the General Electric Company. Each booster is driven by a six-pole, 110-h.p., 600-revolution motor wound for 550 volts and driven from the main railway circuit.

The switchboard, about 50 ft. long, stands 5 ft. away from the south wall. It faces engines two and three, and is built up of standard General Electric panels. It comprises five generator panels, one station panel, three booster motor panels, eight pairs of feeder panels, two booster generator panels, two pairs of panels for the four booster feeders, one rheostat panel and a special panel for controlling the power house and shop motor circuits and the 500-volt lighting circuits. Each generator panel is equipped with a standard M. K. automatic circuit breaker, 5000-amp. current indicator, rheostat, two main switches, voltmeter switch and lighting switch. The station panel carries a G. Q. 5000-amp. Thomson recording station output wattmeter and an illuminated dial Weston ammeter reading to 8000 amps. Each feeder panel carries an M. K. circuit breaker, round dial ammeter reading to 1000 amps., and one double-throw, quick-break switch. The rheostat panel is equipped with an M. K. circuit breaker, 1500-amp. ammeter and three 1200-amp, single-throw, single-pole switches. The booster motor panel carries a circuit

breaker, two main switches, an ammeter and one field rheostat, as well as one starting rheostat, which serves to start any one of the booster motors. The booster generator panels carry an arrangement of switches which allows the engineer to throw the booster current on to either of the two pairs of feeders as desired. They are also equipped with circuit breakers, and in addition with an ingenious relay, devised by the engineers at Schenectady, which comes into action in case the motor circuit breaker trips, opening the booster generator circuit breaker and thereby preventing the generator from running as a motor. At the west end of the board is swung an illuminated dial Weston station voltmeter. The equalizing switches are erected on pedestals in front of each machine.

The lighting of the power house, shops and car barns and the Union Station building is effected from a 50-kw. 125-volt General Electric machine directly connected to a 75-h.p. Harrisburg Ideal engine, the set occupying a position at the west end of the room next to the partition wall. The lighting switchboard is made up of two panels equipped with a 500-amp. Weston ammeter, 150-volt voltmeter, P. C. rheostat, one three-blade main switch and six double-blade, quick-break switches for the separate circuits. The lighting is effected by General Electric inclosed arc single-globe and reflector lamps and incandescent lamps. The inclosed arc lamps in the engine room are swung on brackets made up of a 12-ft. length of gas pipe so hinged that they may be swung against the wall to allow of the passage of the 15-ton Case travelling crane, which travels the length of the room. Ten arc lamps illuminate this room, two over each engine, and each lamp is provided with its own knife switch. Six arc lamps are used in the boiler room. The incandescent lamps are set in three-light clusters scattered throughout the room. These clusters are made up of two railway lamps, one on each side of a 120-volt incandescent lamp. A similar system is followed in the lighting of the basement and the boiler room. All the arc, incandescent and railway branch lighting circuits in the engine room run in tubing. In the basement all the branch circuits to the brackets run in tubing, while the other wiring is run on insulators. In the boiler room the incandescent and arc branches, as well as the railway series circuits, are run in tubing, the other wiring on insulators.

The railway feeder cables drop from the switchboard to the basement, to the ceiling of which they are attached by insulators, rise up the partition wall and run along it to the canal side of the power house. They are then carried on a rack along and over the north side of the boiler room to a bridge crossing the canal. Passing across this bridge they drop down into a manhole, and proceed underground to their several destinations. The feeders are lead-covered 1,000,000-c.m. cables from the Roebling works, Trenton, and are laid in National Conduit Cable Company's conduits, and in Camp and Potomac terra cotta ducts set between the tracks. The first named are iron cement-lined pipes 8 ft. long and $3\frac{1}{2}$ ins. inside diameter. The latter are terra cotta 18 ins. long and of the same diameter. At intervals of about 400 ft. on the straight track and at shorter distances on the curve sections suitable manholes have been constructed between the tracks. Each manhole has concrete walls 12 ins. thick, and on the two sides next to the tracks wooden blocks are let into the cement to support the brackets for the feeder and tap wires. Each manhole is 4 ft. x 4 ft. and 6 ft. deep, but where the conduits drain into them the depth is increased to 7 ft. 6 ins. Slot

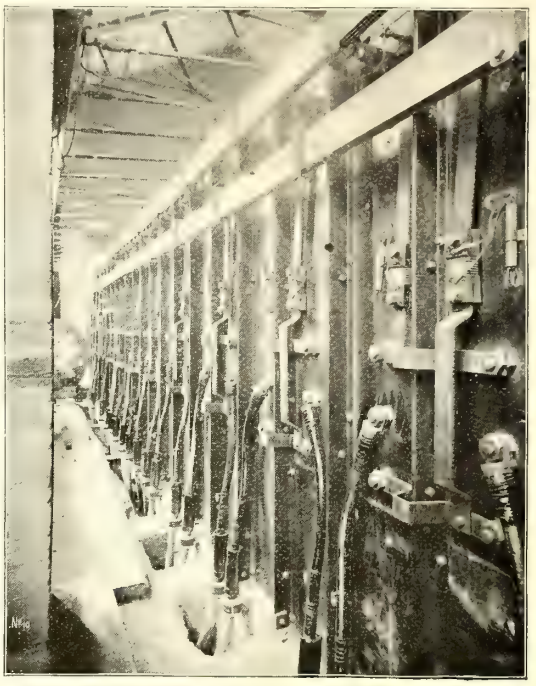


VIEW OF BOILER ROOM SHOWING MECHANICAL STOKERS

hatches are provided at intervals of 800 ft. along the slot, to allow the conductors to be drawn into the conduits and run to their proper positions.

The conductor rails are set 13 ins. to the center below the wheel rails, the distance between the face of each being 6 ins. The conductor rail weighs 23½ lbs. to the yard, with an area of 2.3 sq. ins., and is made up of 31-ft. 6-in. sections. The face is 4 ins. deep and ⅜ in. thick, and the rail is provided with a 1½ x ⅜-in. rib. The conductors are held in position by insulators suspended from a cast iron two-armed cup 5½ ins. deep, with a corrugated inner surface holding a heavy porcelain cup insulator, with exterior corrugations to correspond to the interior of the cup. Between the porcelain and the iron cup cement is poured, which holds the porcelain firmly in place. The bracket support for the conductor is bolted to a stud screwed and cemented into the porcelain cup. The distance between the center of the stud and the face of the conductor is 5⅝ ins. The arms of the cup holding the porcelain insulator are bolted into the slot rail. Over 16,000 insulators in all are used.

Each bracket is also provided with an arm, which is fastened to the conductor rail by two keys. Each length of conductor is bounded to the next by means of two flexible Washburn & Moen copper bonds, having a total cross section of 423,200 c.m.—one bond 11½ ins. long, the other 14 ins. long. These insulator brackets are placed at intervals of 15 ft. 9 ins. on the tangents, and at 9-ft. intervals, or every other yoke, on the curves, and access to each is had by a hand-hole.



The entire length of the main line operated on this

FEEDER CABLES IN BASEMENT OF STATION

underground conduit system is about 22 miles of single track. An angle was riveted to the old slot rail, as explained in the January, 1898, issue, and illustrated in the section of the conduit herewith, and a part of the old track on Pennsylvania Avenue, from Seventeenth Street to the Capitol, a distance of about 1 1-3 miles, was replaced by 6-in. grooved girder Johnson rails weighing 86 lbs to the yard. All rail joints are cast welded. Seventh Street, Georgetown, Fourteenth Street and the Navy Yard sections are laid in 82-lb. 6-in. grooved girder rails.

The rolling stock consists of 188 motor cars and 174 trailers. All the new motor cars are from the shops of the American Car Company, and measure 26 ft. over all. They are mounted upon Lord Baltimore trucks constructed by the Baltimore Car Wheel Company. Each motor car is equipped with two G. E. 1000 A-3 motors, the characteristic curve of which is shown in Fig. 8. The motors are provided with sixty-nine-tooth gear and fifteen-tooth pinion, giving a reduction of 4.6. The series parallel controllers are of the K-9 magnetic-blowout type. Each car

REAR OF SWITCH BOARD

is lighted by three three-light clusters, the extra light burning on either platform as the case may be. All cars are provided with the "Parmenter" front fender and wheel guard, made by George Parmenter, Cambridgeport, Mass., and with registers made by the International Register Company, Chicago.

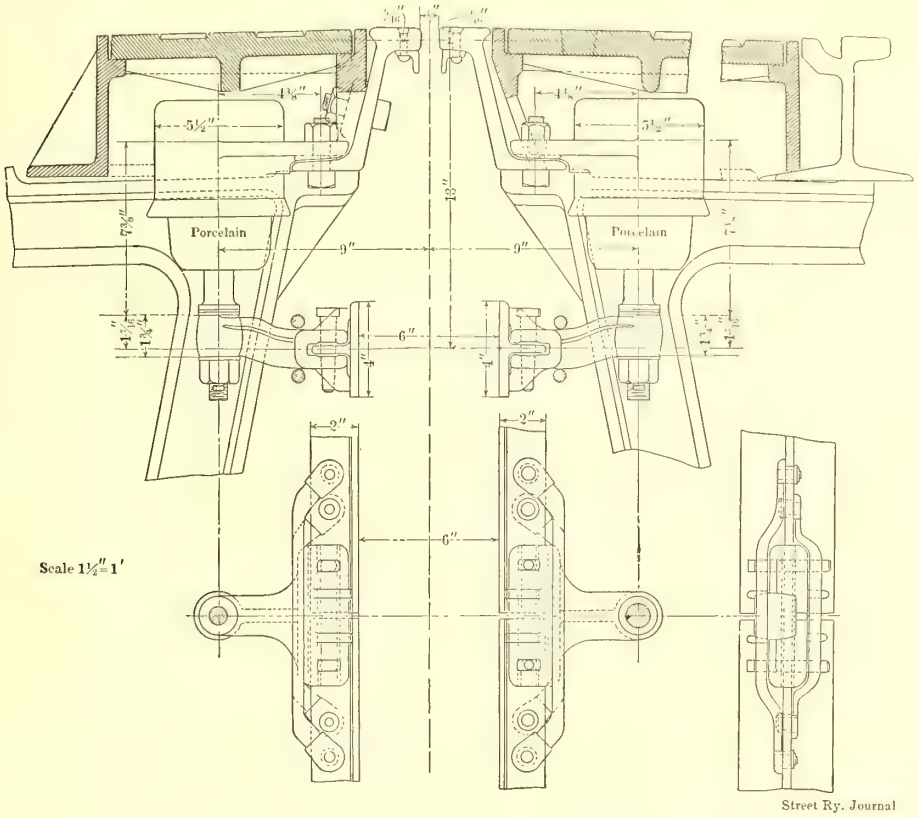
In addition to the rolling stock mentioned above, four Brill snow sweepers are used.

The contact plows used are the forms eight and nine, General Electric plows. Type nine is shown opposite. The plow handle is provided with a slot at each end, and the plow is supported by these slots on two iron bars each 9 ins. long, which run transversely on the truck. The plow can move along them transversely to the truck 4½ ins. on each side of the center, but if it runs more than 4½ ins. it runs off these supports or guides and drops into the slot sufficiently far to allow the bottom of the motors to pass over it without touching it. The conductor connections from the plow run to other connectors attached to hinged couplings on the car. When the plow falls these are pulled apart by the strain, and connection between the plow and the motors is instantly broken. Thus, should the plow follow along the wrong switch, it moves transversely to the truck until it falls from the guides, drops down into the slot and breaks the circuit at the connectors. As it cannot move either vertically or longitudinally the advantages of this construction can be readily understood. This method is intended to prevent delays, which would necessarily occur should the plow jam in the slots at any of the switches, turnouts or crossovers.

The conversion of the Seventh Street line of the same company has also been effected. The remarkable feature of this conversion is that it was made while the cable was

running, without interruption whatsoever to the service. It is the first case of this kind on record, and the skill with which it has been carried out is a tribute to the ability of the company's engineers, D. S. Carll and W. B. Upton, and to the contractor, E. Saxton. The length of the Seventh Street system is about 3 miles of double track. The cable was hauled out on May 25 last, the last cable car hauled into the car barn on the tail of the cable and without interrupting the service the underground contact cars entered upon their duties.

Along U Street, from the junction of the Seventh Street line as far as Eighteenth Street, 1 mile of double track is laid down with the Love system. This terminates at Eighteenth Street, the cars then running under the overhead trolley as far as Chevy Chase, a distance of 6 miles. The Love system will be made uniform with the rest of the system, and may be extended as far as Rock Creek.



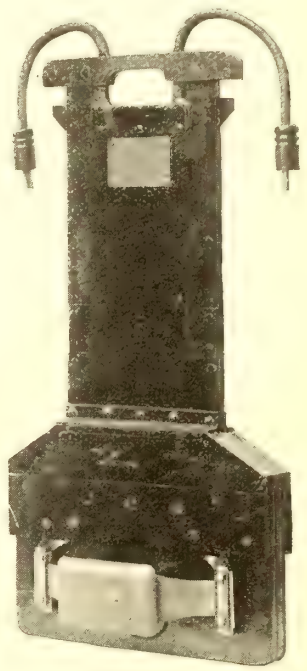


FIG. 4.—PLAN AND SIDE ELEVATIONS OF INSULATORS IN CONDUIT

PLOW

On the opposite side of the canal from the power house, the Capital Traction Company owned another large building, used in the horse-car days as car barn and stable. This has been entirely remodelled, and is now divided into car barn, paint shop, repair shop and machine shop. The car shed has nine tracks, divided transversely by tracks, on which run two transfer tables. Each track is provided with a pit, and floors and pit are of cement. To move the cars a trolley device is employed. This is a small four-wheeled trolley resting on two conductors, strung longitudinally between and over each pair of tracks. From this depend two conductors, which are connected by their own terminals to the plow terminals on the cars. Switches on a slate switchboard on the wall control the car-shed circuits. On track No. 9 is set a Murphy car-wheel grinder, driven by a G. E. 800 motor. Reduction in the speed of the car wheels during grinding is effected by means of water rheostats.

The paint shop is a spacious, well-lighted room, provided with every facility for rapidly handling the cars. The machinery in the repair shop, on the south side of the building, is driven by a 20-h.p. motor, and consists of a planer, joiner, mortising machine, band saw, circular saw, borer and grindstone. On the east side of the car shed are the machine and blacksmith shop, in which the machinery is driven by steam.

In addition to this building, the Capital Traction Company has five car barns in the following localities: Union Station, Georgetown; Navy Yard, Seventh Street, Mount Pleasant and Chevy Chase.

The Capital Traction Company has a capital of $12,000,000. Its officers are G. T. Dunlop, president; C. C. Glover, vice-president; C. M. Koones, secretary and treasurer, and D. S. Carll, chief engineer and superintendent. W. B. Upton is principal assistant engineer; J. H. Hanna, assistant superintendent; H. P. Clark, master mechanic, and Carroll Hashall engineer of power house.

The entire work of installing the electrical system was carried out under the direction of a building committee consisting of the president, Henry Hurt, director, and S. L. Philips, a stockholder. Dr. Louis Duncan was consulting electrical engineer.

An Ingenious Method of Removing Snow from Tracks

The street railways of Detroit are employing snow boards or scrapers attached to the trucks for cleaning snow from the tracks, instead of regular snow plows. The board employed is 2 ft. wide x 10 ft. long and is set on a diagonal under the rear platform. It is shod with iron, and is attached to the side bars of the trucks, which are of the Du Pont type. All the cars run on loops, so that the board always remains under the rear platform. In the case of a light snow storm every fourth or fifth car sent out from the car house carries one of these scrapers. If the severity of the storm should demand it, every car is so equipped. The method has the advantage, of course, that no extra men are needed and that snow is kept off of all parts of the system at the same time. The company also has a leveler, which is run out to throw the snow from the side of the track, where it is piled by the scraper into the gutter, but it is not necessary to run this leveler during a snow storm over any track more than once or twice during the day.

The Three-Phase Electric Railway from Stansstadt to Engelberg

BY CHARLES ROCHAT

The year 1898 will mark an interesting date in the history of electric traction by the application, on a large scale, of the alternating current, utilized directly for the propulsion of electric cars and trains. The first attempt made in this direction was in 1896, when a small city tramway with a length of 4.5 km. was installed at Lugano, but the roads put in operation during the past year leave this modest installation far in the rear.

Several weeks ago the mountain railway up the Gornergrat, near Zermatt, and the first section of the Jungfrau railway from Scheidegg to Eigergletscher were put in operation, and then, most recently, the electric railway from Stansstadt to Engelberg. It is this latter road that I now wish to describe to the readers of the STREET RAILWAY JOURNAL.

VIEW FROM FOOT OF 25-PER-CENT GRADE—THREE PHASE RAILWAY

By a half hour's trip by boat from Lucerne, the starting point for tourists in Switzerland, and in the center of a region of that incomparable beauty which characterizes central Switzerland, is found the small town of Stansstadt, which is located in the canton of Unterwald. It is here that our railway commences. It then traverses the little coquettish town of Stans at the foot of the Stanserhorn, and the capital of the demi-canton of Nidwald. It then rises through the entire length of the beautiful valley of Engelberg to come out at the locality of that name, after traversing a distance of 22.5 km. The profile of the railway is represented on the map herewith (Fig. 1), which gives the names of the stations.

From Stansstadt as far as Obermatt, where the power station is located, or about 18 km. (11.2 miles), the track is of the ordinary type, depending upon adhesion for traction. From Obermatt to a place called Gherst the roadbed is furnished with a rackrail of the Riggenbach type, the same as that used on the Rigi; then from Gherst to Engelberg the track is again of the ordinary adhesion type. The rackrail has a length of 1.54 km. (0.95 mile), and the grade surmounted by its help has an average of 25 per cent. The maximum grade on the sections depending for traction on adhesion are 5 per cent, and the minimum radius of curves is 50 meters (164 ft.). The track is built of Vignole rails weighing 20 kg. to the meter (41 lbs. per yard), placed on metal ties of 22 kg. (48 lbs.) The rails have a length of of 10.5 m. (34.6 ft.), and the ties are spaced eleven to each rail length.

The problem of equipment has been complicated, as can be easily seen, by the presence of a section of rack road, laid in between the two sections of ordinary track. After a study of the conditions the engineers decided to employ large cars with a seating capacity of forty-eight, operated as motor cars on the ordinary sections, and drawn on the rackrail section by an electric locomotive.

The entire line passes through a very interesting country, and beautiful vistas are presented on the trip. It is built upon its own right of way and not upon highways. The stations are tasteful in design, and the depots are furnished with facilities for handling baggage. This makes the system resemble a railway more than an ordinary tramway.

ELECTRICAL EQUIPMENT

The character of the current adopted is the three-phase alternating, supplied directly to the motors of the cars and the locomotives by means of two trolley lines carried overhead at a height of 4.5 meters (14.9 ft.) above the track and supported 0.9 meter (2.96 ft.) apart. The rails form the third conductor for the system. The diameter of the trol-

ley wire is 7.5 mm. (.295 in.). They are supported by steel span wires of 5.5 mm. (.216 in.) diameter, held between two wooden poles placed on each side of the track and about 35 meters (115.5 ft.) apart. The poles are of spruce, creosoted, and have a diameter at the base of 230 mm. (9 ins.) and at the top 170 mm. (6.7 ins.) All the mechanical details of the construction of this line have been calculated with a factor of safety of four against breakage. The trolley line has a double insulation against the soil. The insulators employed were supplied by the Billings & Spencer Company, of Hartford.

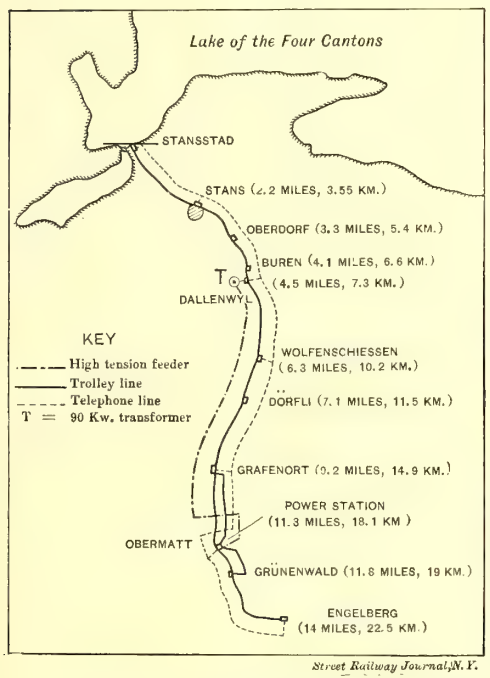
The three-phase current is produced at the power station at a potential of 750 volts, and for the section immediately adjoining the station is conducted directly to the trolley wire. The power station is located close to the track at Obermatt. In addition, feeders are run from the power station to Grafenort for one section and to Grünenwald for another section, in order to reduce the loss of voltage on those parts of the line having the steepest grades. To feed the section situated near Stans, a part of the current of the generators is led into a transformer of 90 kw., and is raised from 750 volts to 5000 volts. This high tension current is carried by an overhead conducting system of three wires of 3.5 mm. (.141 in.) in diameter each as far as Dallenwyl, situated at 11.1 km. (6.9 miles) from the power station. Here it is led to another transformer, which lowers the tension from 5000 volts to 750 volts. This second transformer is also of 90 kw. capacity.

The generators have a capacity of 200 h.p. each, operate at a speed of 650 r.p.m. and are each driven by a separate impulse wheel, working under a very high head; the number of periods in the current is 3900 per minute. Two generators are at present installed. They are excited by two small continuous current generators of from 10 to 12 h.p. each, operating at a voltage of 110 and running at 1800 r.p.m. Each of these is driven by a small turbine.

The power station, shown on page 20, is built with a capacity of three generating units, and can be enlarged if the needs of the traffic require it. The switchboard carries the usual apparatus, such as voltmeters, amperemeters, circuit breakers, etc. In the rear of the board are the fuses and the different connections of the transformer, to which reference has already been made. The overhead wires are protected at the point where they leave the station by lightning arresters of the Siemens horn type, placed on the first pole of the line. At the side of the station is a siding for the electric locomotives.

An interesting feature is the method of braking; when a train descends the grade of 25 per cent the motors of the locomotive are connected in parallel with the generators at the central station, and so produce a certain amount of power. This power is utilized directly in part by the other cars on the section, but as the amount of power produced in descending this steep grade is generally greater than the consumption of the other trains, the surplus has to be absorbed in some other way. Consequently at the central station there has been installed a water rheostat, consisting of three rails laid in the discharge canal from the turbines. The distance between these rails and their length has been so adjusted as to permit their absorption of from 140 to 240 h.p. When a train starts to descend the steep grade the central station is advised of the fact by telephone, and the engineer at the central station throws in the water rheostat by means of two special switches. The system, although somewhat primitive, has given excellent results so far.

Another interesting feature is the device intended to prevent accidents from the breakage of the wires of the 5000-volt circuit. The State railway department has imposed on the Stansstadt-Engelberg Railway Company the following condition: to install a device which will immediately interrupt the current in case of a break of the high tension wires. Complying with this, the company has installed the device illustrated in Fig. 5. The primary coils, *A*, *B* and *C*, of the three small transformers, are connected



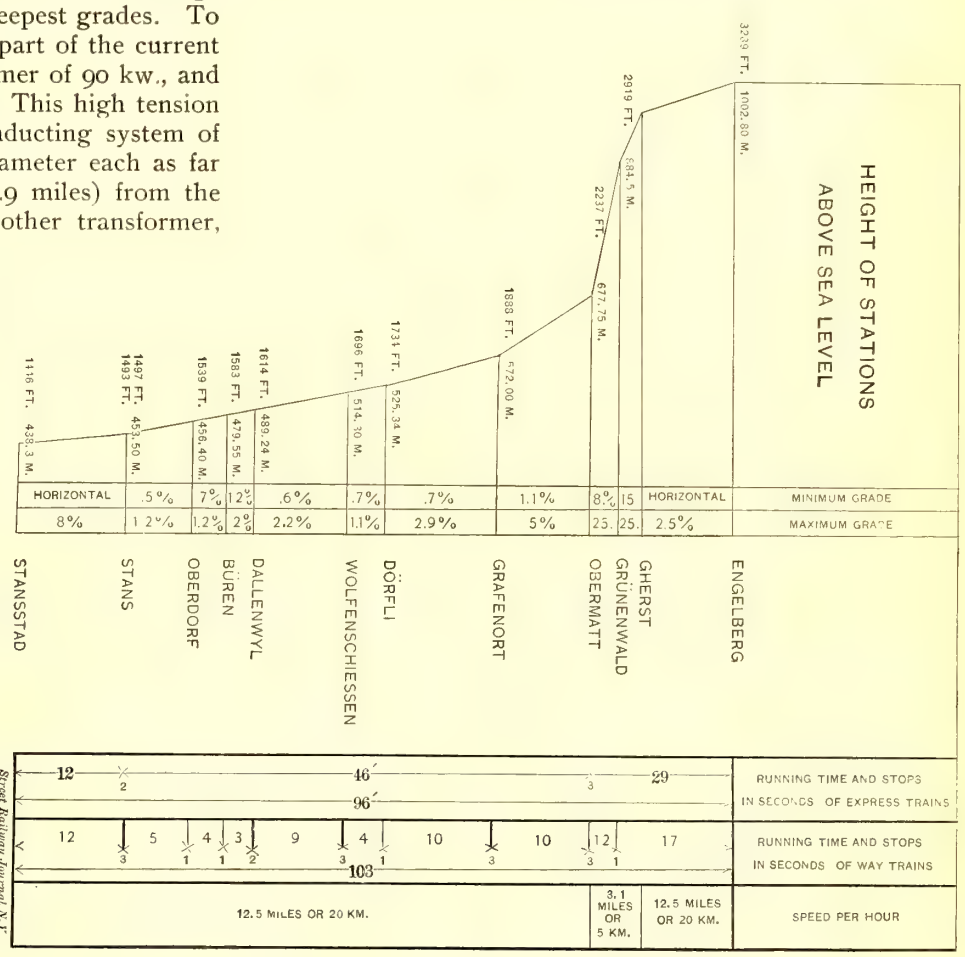


FIG. 1.—MAP OF LINE SHOWING FEEDERS

FIGS. 2 & 3.—PROFILE AND RUNNING TIMES

to three wires of the high-tension circuit at the points where they leave the station, and possess a common point *o*, which is led to earth. The secondary currents of these three transformers are connected in series to single circuit, in which is connected the apparatus which will produce the interruption of the primary circuit at the moment designed. The secondary e.m.f. of these transformers is 50 volts. The automatic circuit breaker in the circuit at *I* is an arc lamp. The following result is then secured: When there is nothing abnormal in the circuit, that is to say, when there is no broken wire, there is an equilibrium of the entire system, and the secondary coils of the three small transformers are not transversed by any current. When, on the other hand, any one of the three wires is broken, the equilibrium is interrupted. The unequal

I = Automatic circuit breaker (arc lamp)

FIG. 5.—DIAGRAM OF CONNECTION OF AUTOMATIC CUT-OFF

phases excite the secondary coils and the current circulates in the lamp circuit arranged, so that the moment the carbons light they interrupt the exciting circuit of the generators. The tests made with this apparatus have consisted in letting a wire of the transmission circuit fall to the ground, and have shown that the interruption of the exciting circuit of the generators is produced in a length of time varying from four to seven seconds. The effect is then not absolutely instantaneous, but it would not be difficult to increase sensibly the rapidity of its operation, for example, by substituting for the arc lamp a circuit breaker which would open the circuit almost instantaneously. To avoid the disastrous effect of a sudden interruption of the current it would be possible to substitute for the circuit breaker an automatic switch, which would shunt the exciting current through a rheostat in series with the main switch on the exciting dynamos. The exciting circuit being 110 volts, there is not much danger, however, in breaking the circuit quickly. There is another inconvenience, however, in that the apparatus might be too sensitive, and that it might be operated by lightning. This arrangement, although somewhat crude, is still interesting to mention, for it is possible of having wide application, the high-tension lines being extremely numerous and the dangers resulting from them increasing with the number of installations.

ROLLING STOCK

The rolling stock is composed of two electric locomotives, five motor cars and four freight cars. The locomotives, which have a weight of 16.5 tonnes (36,300 lbs.), are intended, as stated, to draw the cars on the rackrail section, as well as to handle the freight trains. These locomotives are mounted on two axles, and are equipped with two electric motors of 75 h.p. each, and drive the rack gear wheel by a double reduction gearing. The motors operate at a speed of 650 r.p.m., and the speed on the rackrail is 5 km. per hour. In addition, the locomotives are so built that the rack gear can be disconnected, and they can operate on the ordinary sections at a speed of 11.5 km. per hour.

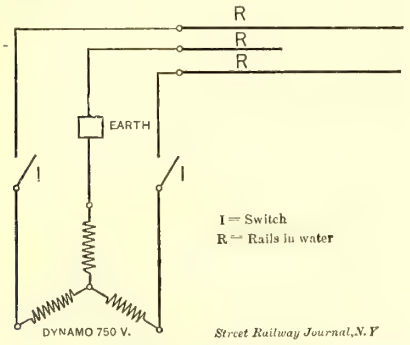
G = Alternating generator, 750 Volts. E = Exciter, 110 Volts.
R = Regulating rheostat. T = Transformer, 750/5000 Volts.

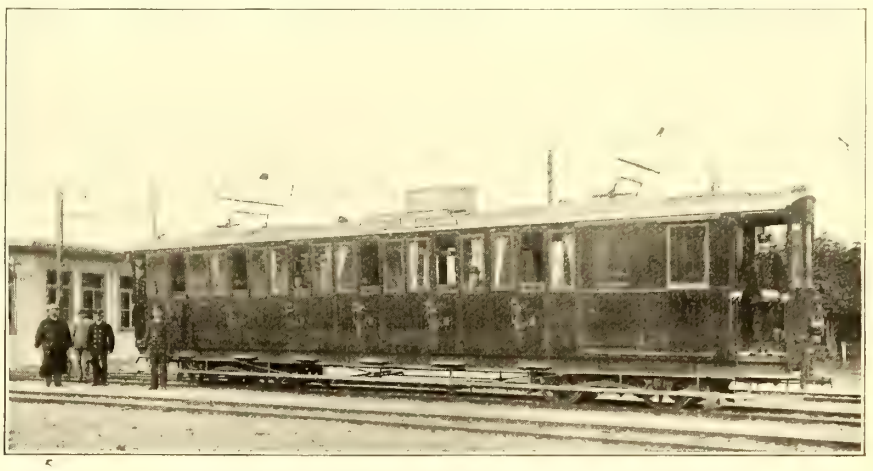
FIG. 6.—DIAGRAM OF STATION CONNECTIONS

The equipment of the locomotives includes a switch, a diverter, a volt and ampere meter, lightning arresters and fuse plugs. The duties of the engineer are very simple. He closes first the main switch and slowly cuts out the resistance which is in the circuit of the motors. The motors operate then in synchronism with the generators of the power station and at a constant speed, independent of the load drawn. When ascending a grade of 25 per cent and pushing a motor car completely loaded the locomotives absorb an average of from 95 to 100 amps. at 750 volts. In descending and with the same conditions of load, the motors furnish a current from 60 to 65 amps. going up to a maximum of 75 amps. The current is taken from the overhead wires by means of two sliding bow contacts, which are composed of two long cylinders of aluminum separated from each other by a piece of wood soaked in paraffine. The bow system of contact has been adopted in order to avoid the difficulties of construction with overhead

frogs, which were not considered desirable with two trolleys. The bows have given up to the present excellent satisfaction.

The locomotives are fitted with the following braking apparatus: first, ordinary brake shoes that operate on the four wheels; second, the motors working as generators when the current is reversed, the speed of the motors being constant whether they work as motors or generators; third, the emergency brake, operating simultaneously on the two grooved pulleys or drums, of which one is mounted on the shaft of the motor and the other on the countershaft placed between the motors and the axles. These two brakes are connected mechanically together in such a way that the pressure divides itself uniformly on the two axles. When the eight brakeshoes are applied a pressure is brought to bear against the grooved pulleys at the same time. The rack brake is operated in two different ways, by hand and automatically. To secure this a speed governor is used, which puts the brake in operation when the speed exceeds the normal. Moreover, when the main switch is opened the brakes are automatically set.





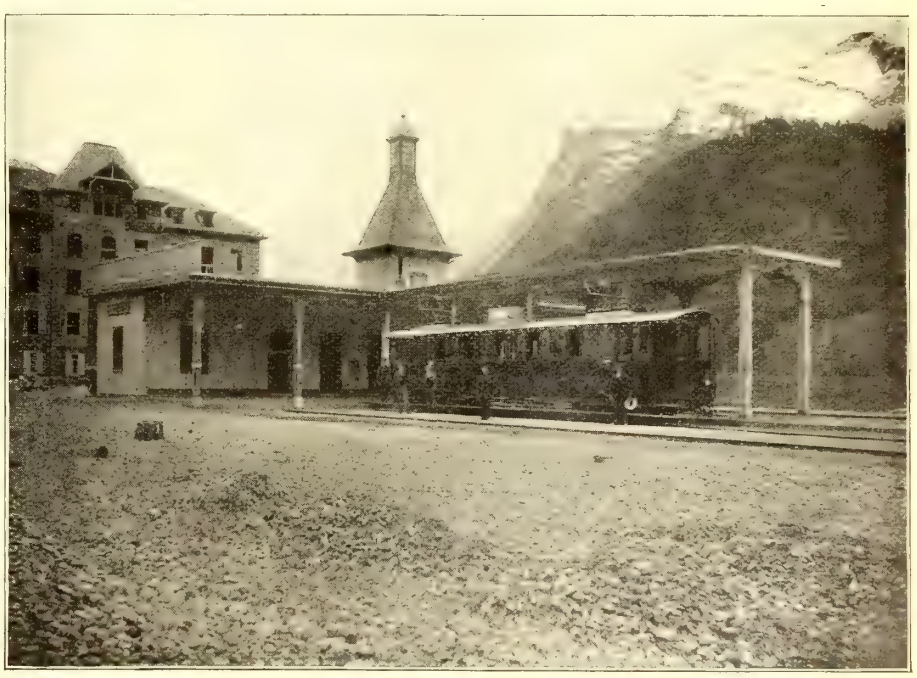


FIG. 7.—CONNECTIONS OF STATION WATER RHEOSTAT

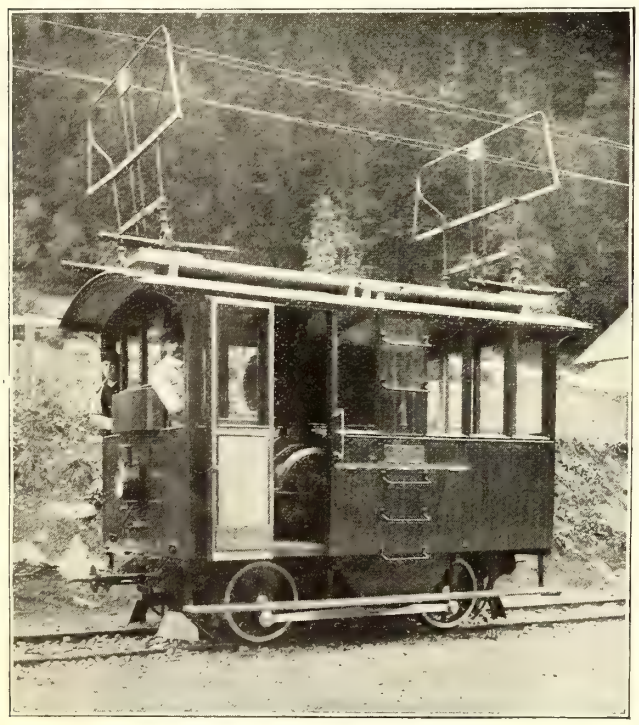
STANDARD MOTOR CAR

The locomotives for driving gear are fitted with two shafts, of which one is supplied with a gear toothed for fitting into the rack. The motors drive an intermediate shaft placed between the two main car axles, and on which is mounted a toothed pinion, which is loose on the shaft. This pinion is operated by the electric motors through the intermediary of two trains of gears, reducing the speed in the proportion of about 15 to 1, for operating on the rack. Each motor transmits its work by a pinion of 156 mm. (6.1 ins.) diameter, mounted on the extension of its shaft. This pinion engages with a gear of 1092 mm. (43 ins.) diameter mounted on an intermediate shaft. On this shaft are found two other gears of 256 mm. (10 ins.) diameter, which engage in their turn with two gears of 608 mm. (24 ins.) diameter placed on each side of the toothed wheel engaging in the rack. The intermediate axle on which are mounted the two gears of 256 mm. (10 ins.) carry at their ends a friction coupling in order to throw the regular wheels into gear. The driving gear in the rack is then always connected mechanically with the motors, while the driving wheels are uncoupled during the ascent on the rack. For operating on the ordinary line, the friction coupling is thrown in and power is transmitted through the car axles through the intermediary of two gears of 432 mm. (17 ins.) diameter connected by means of cranks with two others of the same diameter mounted on the car axles. Below the motors is a diverter, operated by a handle, which connects the carbon contacts with the different sections of the resistance. All of the controlling mechanism of the locomotive is located in the cab, which is furnished on all sides with windows and has two doors.

The motor cars at present are five in number, and have a length of 14 meters (46.2 ft.). They are mounted on two trucks having a wheel base of 1.80 meters (5.94 ft.) and spaced 8.30 meters (27.9 ft.) apart. The car is built according, in compartments, to the French system. The number of these compartments is six, not counting the compartment for baggage placed at the end of the car. The number of seats varies from 44 to 48. The two platforms are inclosed by a vestibule, the windows of which can be lowered at pleasure. The forward platform is reserved for the motorman, who has at hand the following apparatus for controlling the speed: a switch, a lever for throwing in the resistance of the diverter, and hand brake.

STATION AT ENGELBERG



The approach of the car is signaled by means of a horn,

and the car carries a small, primary battery, so that the conductor, who is on the rear platform, can signal to the motorman on the front platform. The two motors are carried on the two axles of the same truck; they are of 35 h.p. each with six poles, revolve at 480 r.p.m. and drive the axle by gearing. The free swivel truck is furnished on one axle with a toothed gear engaging in the rack and arranged to be braked by means of an emergency brake carried on the rear platform of the car. The efficiency of the motors at full load is 80 per cent, including the gears.

The regulating resistance, which is thrown in the induced circuit of the motors, is carried on the roof of the car and enclosed in a water tight case. The electric equipment of the cars is completed by fusible plugs and lightning arresters, as well as lamps for the general lighting of the interior of the car, and two signal lamps carried regularly on the hood.

OPERATION

As stated, the distance from Stansstadt to Obermatt, where the power station is located, is about 18 km. (11 miles) of ordinary track, on which the grades do not exceed 5 per cent. This section is operated by single motor cars, which are designed to be capable of drawing one trail car. They weigh 5 tonnes (11,000 lbs.) empty, and 26 tonnes (57,200 lbs.) loaded. At Obermatt the motor car first runs on the rack for about 20 meters (66 ft.). Then the electric locomotive is run up behind it, and, without coupling, the train proceeds up the grade under the power of the locomotive only. The rack has a length of 1540 meters (5050 ft.) and terminates at Gherst. On arriving at that point the motorman on the car turns current into the motors and the car proceeds under its own power without

ELECTRIC LOCOMOTIVE

being obliged to uncouple from the locomotive, as explained above. The locomotive remains at Gherst to wait for the return car. A siding at this place permits two trains to follow each other, if desired, the locomotives being shunted onto the siding. To descend, the motor car runs on the rack section just far enough so that the gear wheel of the emergency brake is able to engage in the rack. Then the locomotive is coupled onto the car and the descent commences. When they arrive at Obermatt the locomotive is uncoupled and is then shunted onto the siding, and the motor car proceeds independently after about two minutes required for uncoupling. The speed of the cars is absolutely constant, a result which naturally follows the use of the alternating current, and on the ordinary track is about 20 km. per hour, although on the rack section it is only 5 km. per hour, owing to the change in gearing. The speed is the same in descending and ascending.

From the standpoint of the operation of locomotives and motor cars this constant speed is without doubt of ad-

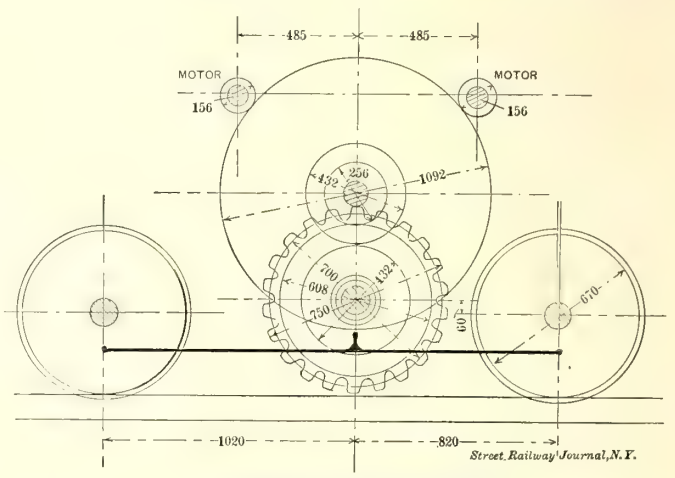


FIG. 8.—GEARING FOR LOCOMOTIVE

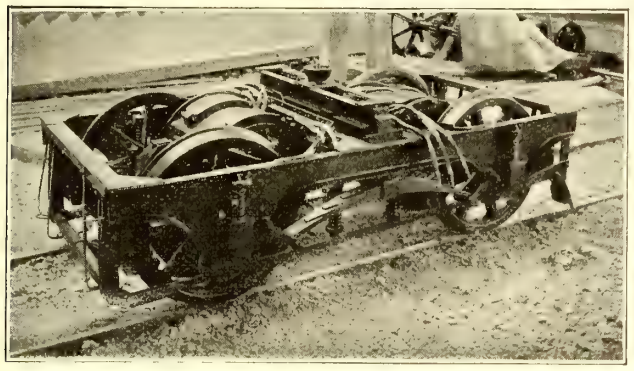
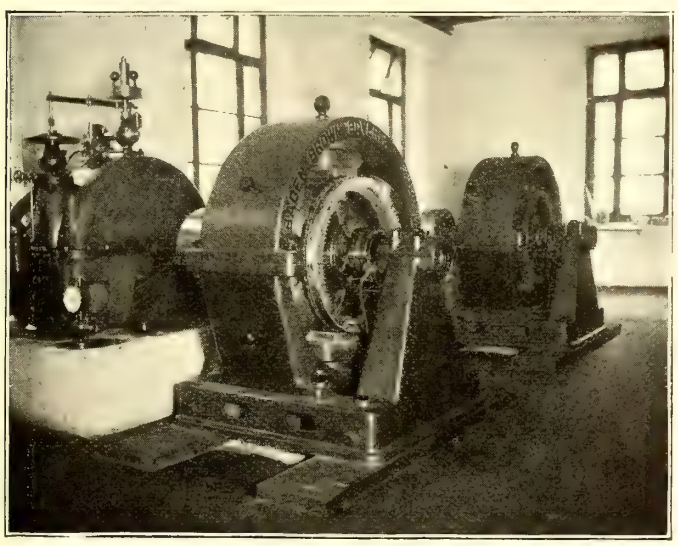
vantage, for the motorman is not able to waste current by lack of judgment; in a word, to take liberties with the timetable. He has absolutely only to close the switch and to cut out the starting resistance. This comprises all his work. On the other hand, from a practical standpoint, it is often desirable to be able to vary the speed within certain limits, either to gain lost time or else to vary the speed according to grades of the track, curves, where the car is passing through towns, etc. From this standpoint a three-phase current as applied in this instance has a disadvantage as compared with the continuous current, for the latter is undoubtedly much more flexible in its employment.



The different stations are connected between each other by telephones, using a complete metallic circuit to overcome the effect of induction and leakage from the alternating currents used. The two telephone wires are crossed every five poles, corresponding to a distance of about 175 meters (574 ft.). The wires of the public telephone system, which parallel the railway for a considerable distance, have been crossed every pole to eliminate induction. Since this was done the telephone circuit works very satisfactorily.

CONCLUSIONS

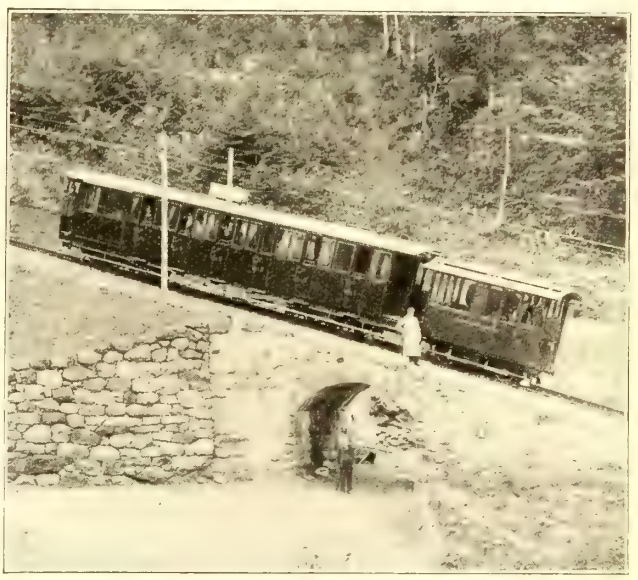
One great advantage of the direct application of the three-phase alternating current for traction lie in the facility of transporting the electric energy over considerable distances at high tension and of reducing it to a working voltage without recourse to rotary transformers, which are more or less complicated and expensive. The transformers for the alternating current are simple, take little space and require practically no attention. There are other advantages, however. The motors are of simple and strong construction as compared with continuous current motors, and have no commutator. On the other hand there are some undoubted drawbacks. Reference is not made to these to cast any discredit on the builders, who deserve great credit for their pioneer work, but to call to their attention those points which are yet capable of improvement.



From a construction standpoint the overhead line is undoubtedly more difficult to build, more costly and more

heavy than that required for a continuous current. The installations at switches are particularly complicated and heavy. The difficulties attending the taking of current from the trolley wires are considerable, especially with the system of bow contact, where there is no guide to the

MOTOR TRUCK



current collector. From an operating standpoint the great disadvantage is the necessity of maintaining a constant speed whether on grades or on level; that is to say, without regard to the work required of the motors. It is absolutely illogical, for example, that a car should have a speed of from 18 km. to 20 km. per hour on levels and on grades. On the former the speed ought to be much greater than 20 km., and descending a grade it ought to be somewhat less. There is another disadvantage of the system in that there is absolute dependence on the trolley line for operating the electric brakes. An example will demonstrate this. Let us consider our car descending a

GENERATOR AND TURBINES

grade of 5 per cent at a speed of from 18 to 20 km. per hour, and that we have good contact with the overhead wires. The motors are in phase with the generators and the speed cannot exceed or be less than that determined by the periodicity of the latter. Let us suppose that the current suddenly stops or that the generators are cut out for some cause or another. Our car immediately acquires a high speed, which may become dangerous if the car be not immediately checked by the ordinary mechanical brakes. With a continuous current where in descending grades the motors can be made work as generators it is possible to maintain the speed within desired limits, and this can be done with complete independence of the overhead line.

The foregoing are briefly certain critical considerations which suggest themselves to me in comparing the continuous alternating current as applied to electric traction. The criticisms, as stated, are not directed against the builders, whose work at this installation ought to be considered as a valuable contribution to the science of electric railroading. The objections may no doubt be overcome, and the alternating current, in the future, may be a considerable if not a formidable rival of the continuous current, at all events, under certain conditions. In conclusion I wish to express my thanks to the builders of the line, who have kindly supplied me with information for this article, viz.: Messrs. Brown, Boveri & Company, of Baden,

CAR AND LOCOMOTIVE DESCENDING 25-PER-CENT GRADE

Switzerland, who carried out all the electric work; La Société Industriele Suisse, at Neuhausen, who supplied the cars, and La Société Suisse pour la Construction de Locomotives, at Winterthun, who build the two electric locomotives.

Electrical and Repair Shop Practices in Philadelphia

It is the practice of the superintendent of the overhead lines and cables of the Union Traction Company, of Philadelphia, to furnish the emergency repair men blue prints showing the trolley sections fed by each cable. These blue prints are numbered, and sections belonging to power station No. 1 run from 1 to 199; those from station No. 2, from 200 to 299, and so on to the other stations, of which there are seven, and one battery station, the latter being of the chloride accumulator type. These blue prints show all the trolley sections in detail, giving the location of points where connection is made from the underground cable to the trolley wire and the location of section insulators. The number of the adjacent sections are also given, as shown by the accompanying sample print, Fig. 1.

Since the consolidation of the different companies there has been a rearrangement of feeder lines, so that the different stations are coupled in the most economical manner, resulting in a large saving of current and copper by the transfer of cables to new districts. It should be remembered that in this system nearly all feeders are carried underground in the company's own conduits. There are over 1000 miles of underground cable, composed of 620 miles of lead-covered feeder cable, 170 miles of telephone cable, and 210 miles of return cable. Since the burning of

the Thirteenth and Mt. Vernon Street station, and the consequent disarrangement of the cables in the power-house vaults, a systematic arrangement of the cables in these vaults has been effected, and the contrast is shown in the accompanying illustrations.

Fig. 2 shows the condition of a portion of one of the vaults before the change, and Fig. 3, the same manhole,

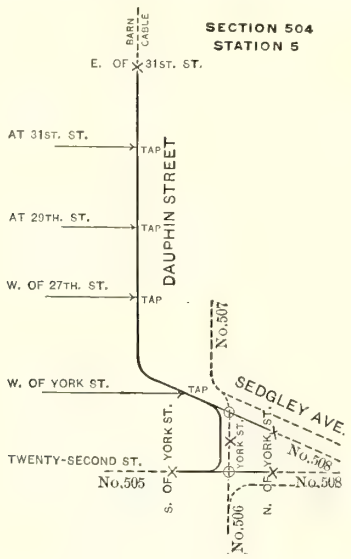


FIG. 1.—SAMPLE LINE MAN'S SHEET

with the cable systematically arranged. Figs. 4 and 5 also show how order was brought out of confusion in another vault. Fig. 6 illustrates the method of supporting lines of lead cable round a corner and also from the ceiling. In this connection, however, it may be noted that a peculiarly formed metal bracket has recently been devised by this

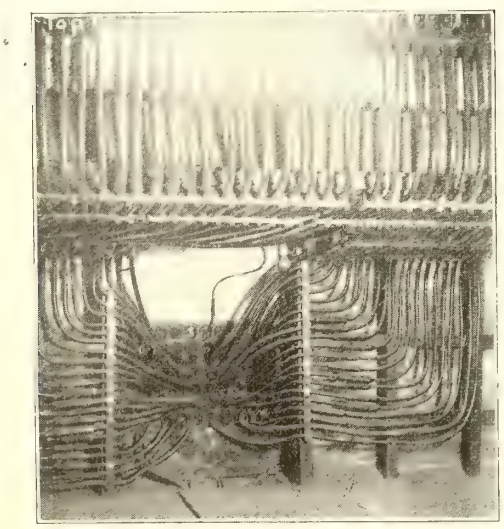

FIG. 3.—SYSTEMATIC ARRANGEMENT OF CABLES SHOWN IN FIG. 2

department. It is intended to replace the wooden strips used in the manholes, as the supports made from wood are found to rot out after about three years of service.

Five plumbers with the necessary number of helpers are employed in keeping the lead-covered cables in proper repair.

TELEPHONE SERVICE

The company maintains an independent telephone system of about 100 instruments, which connects the department offices, and also the emergency stations, power houses and car houses. The system is known as that of the Standard Telephone Company, and an independent switchboard is provided. The current for operating the call circuit of the telephone system is generated by a pair

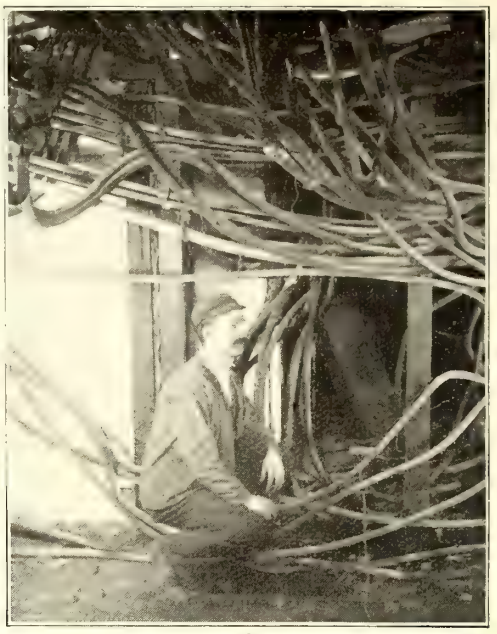

FIG. 2.—CABLES IN VAULT BEFORE CHANGE

of motor dynamos, which are located in the same room as the switchboard. There are two of these machines, but only one is operated at a time. These machines are of the Crocker-Wheeler type, and transform a 500-volt direct current down to 75 volts alternating. The switch connected with these machines is provided with an automatic cut-out and rheostat, so that if the current breaker in a power station opens, the current is automatically cut off from the motor transformer.

An operator is always on duty, who also acts as emergency dispatcher and keeps a record of all calls answered by the emergency wagons. Trouble of all kinds is re-

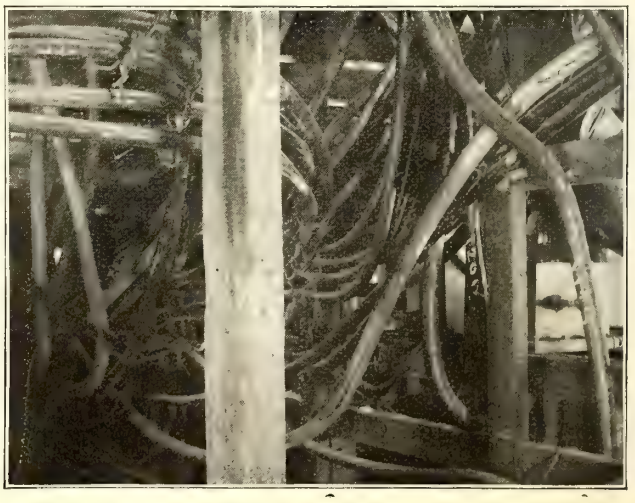

FIG. 4.—ANOTHER VIEW OF CABLES BEFORE ARRANGEMENT

ported to the central office, and this department is also connected with the city fire alarm signals, the emergency wagon running on each fire alarm, the same as the fire engines. At fires, the tower wagons are frequently used as hose bridges, so that the cars are allowed to pass through. Each wagon crew is composed of a lineman, helper and driver, and the lineman reports by telephone

the nature of all the calls to which he may respond and the time consumed.

The company employs eight emergency tower wagons, six of which are on duty throughout the twenty-four hours, and two that are on duty for twelve hours. These tower wagons are of the McCardall & West type, manufactured at Trenton, N. J.

Some idea of the work required of this department can

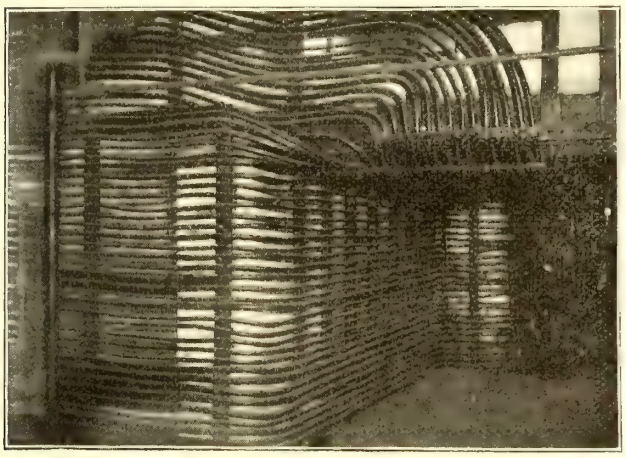

FIG. 5.—SYSTEMATIC ARRANGEMENT OF CABLES SHOWN IN FIG. 4

be formed from the statement that the system embodies about 500 miles of trolley wire and 300 miles of overhead feeder cable. No. 00 trolley wire is used in re-equipment throughout the entire system. The overhead construction is supported by tubular iron poles 30 ft. in height and in three sections; the telescoped sections are 7 ins., 6 ins. and 5 ins. A special device is employed at the overhead crossings, which prevents the wearing out or crystallizing of the trolley wire at these points. This consists of a sheet of steel about 3 ft. in length and 4 ins. in width placed above the wire with the ends turned up, and so arranged that when the trolley wheel approaches the crossing the flanges of the wheel come in contact with the curved plate, freeing the groove from the wire and relieving the latter from the blow that is otherwise dealt at the rigid point.

REPAIR SHOPS

In the main repair shop, which is at the corner of Eighth and Dauphin Streets, there is a home-made electric transfer table, Fig. 7, which eliminates almost all the hand labor required for shifting cars. This table is of sufficient length to accommodate the longest and heaviest cars, and plies between the repair shop on one side of the track, and the wood working department on the other, and crosses the tracks of the repair pits and the station storage tracks.

The table operates on four tracks, which are slightly depressed, so that the tracks on the platform are on a level with the shop tracks. The current for operating the motor

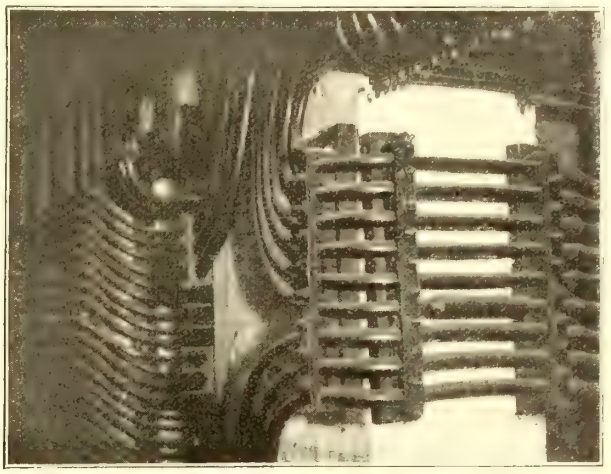

FIG. 6.—METHOD OF CARRYING CABLES AROUND CORNER

is collected by an under-running trolley, which is in contact with a T rail, used as a conductor. This rail is embedded in asphalt between the track rails, and its surface is about 2 ins. below the asphalt paving. An ordinary car motor of the G. E.-800 type, with type K-2 controller, is employed, and this is geared to the main axle, as in car practice. The resistance coils are in three sections, and boxed in directly under the main axle. The fuse box and switch are placed near the operator. Each axle has four wheels, those on the motor side of the table being 30 ins. in diameter, of special pattern undished, while the wheels on the opposite side of the table are 15 ins. in diameter. The outside wheels of each set are plain, without flanges and their axles are coupled to the driving axle by a peculiar clutch coupling, which allows them to turn independent of the driving axle. Roller bearings are provided for each journal, and these are what are known as the Standard roller bearing.

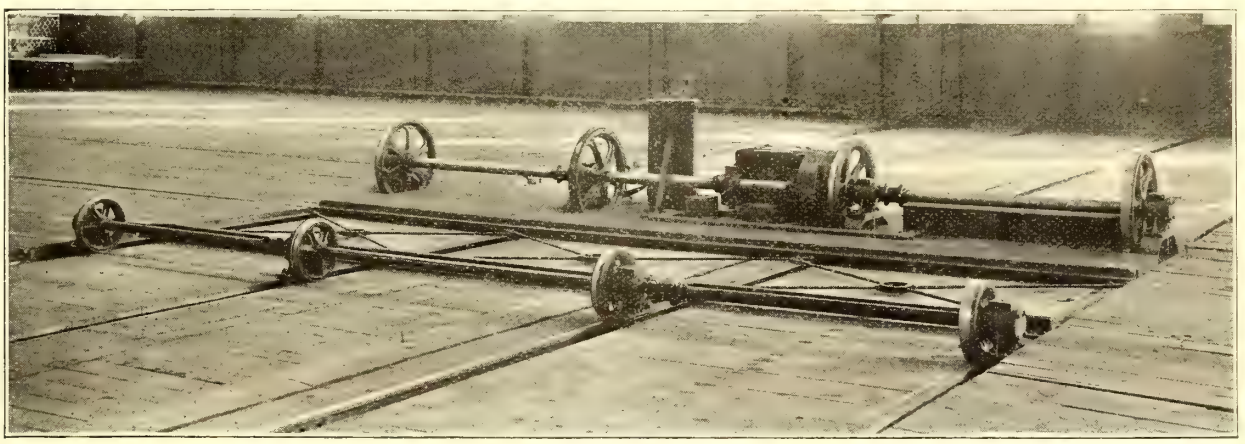

FIG. 7.—ELECTRIC TRANSFER TABLE—EIGHTH AND DAUPHIN STREETS

The middle driving wheel next the controller is provided with a band brake, which is operated by a foot lever within easy reach of the operator. The table runs very rapidly, and is readily controlled by the brake. The company has two of its shops equipped with this type of transfer table, and both are giving excellent satisfaction.

LETTERS AND HINTS FROM PRACTICAL MEN

Reversible Street Railway Rails

Philadelphia, Pa., Dec. 2, 1898.

Editors Street Railway Journal:

The reversible girder rail is by no means a new idea. Such a rail was patented in England and Germany many years ago, and, as is well known, is used to-day largely in Great Britain and on the Continent of Europe; however, the rail forms which I illustrate in this letter are, in matter of design, proposed method of manufacture and application, original with the writer.

It is well known that in cities, under heavy traffic, the average life of the straight-line rail is from seven to ten years only; on curves this life is reduced to from two to six years. In Europe, the experiment of reversing double-headed rails on steam roads has proved a failure, due to the fact that the double or "bull"-headed rail is set on chairs, and the wear is thus concentrated on that part of the rail in contact with the chair. The consequence is that the rail is worn on the under side, and presents a series of indentations, sometimes amounting to as much as an eighth of an inch in depth.

This indentation of the rail does not occur when the rail is in contact with wood or has a uniform bearing of large surface on metal or concrete. As a maintenance of way engineer and one engaged in the manufacture of rail work, it has been a study with the writer for years how to increase the life of rails, and, while an earnest advocate of

PROPOSED SECTIONS OF REVERSIBLE RAILS

high carbon and special steels, yet even the recourse to such has not solved the problem of economical maintenance, in the writer's opinion. In the illustration are shown several designs of reversible rails; some of these are no doubt of little utility; others are superior.

Figuring at the present price of steel rails, their average life and renewal costs, allowing current prices for scrap, with interest on increased investment in the case of the reversible rail, also taking into account additional present cost of rolling the reversible rail, it appears that this form of rail presents an economy of at least one-third over the present form of rail. The pros and cons may be stated as follows:

AGAINST

1st. Increased cost of rolling.

2d. Increase of capital in investment, due to increased weight of rail.

3d. Difficulties of fastening.

4th. Fatigue of metal.

FOR

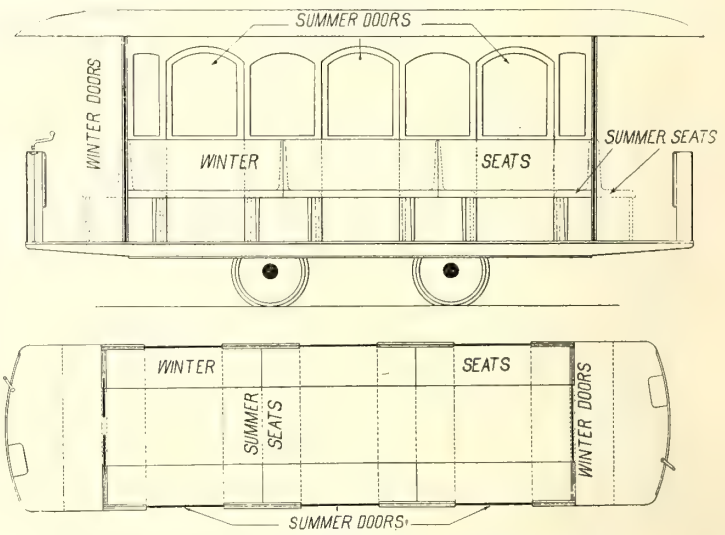
1st. Increase of life, double that of single head.

2d. Ease of change, when renewal comes.

Answering objections, I would state that with the method of rolling which I propose, the cost will not be increased, and a better rail will be obtained than in the case of a thin base, making a rail subject to internal stresses. It is true that the capital investment is slightly increased, but this is more than offset by gain in efficiency.

With the New York type of rail, shown at the extreme right, there is no increase of difficulty in fastening the rail to the tie over the ordinary base rail, and with the other forms it is generally proposed to use a concrete roadbed, which overcomes any difficulty of this kind. The concrete roadbed for street work is used so successfully abroad and at home that its introduction in such an event may be considered on the line of improved practice.

The fatigue of metal in a rail long in use would be an argument against in steam road practice, but conditions are radically different on the street railways, where the breakage of rails in use is rare. With the tremendous traffic developed by electric service in cities has come the demand for something more permanent than what is known abroad as "permanent way," but which unfortunately hardly deserves this title. Figuring the length of street railways in the United States at 12,000 miles, and assuming the average weight of rail 70 lbs. to the yard, which is low, the annual saving per mile of track per annum would be $136.19, or a total for the United States of $1,634,280, representing at 4 per cent a capitalization of $40,857,000. On such a system as the Union Traction Company, of Philadelphia, the annual saving would be nearly $70,000.



G. W. Chance.

Proposed Convertible Car

Johnstown, Pa., Dec. 5, 1898.

Editors Street Railway Journal:

Upon reading your editorial upon convertible cars in the current issue of the Street Railway Journal, the construction shown in the sketch herewith suggested itself. Upon examination and research it will probably be found "as old as the hills," yet I cannot remember seeing it before. The length of the car must be a multiple of the width, which permits the same seats to be arranged lengthwise or cross wise for winter or summer, as desired. The sketch

SIDE ELEVATION AND PLAN OF CONVERTIBLE CAR

illustrates a car 18 ft. body, having three doors in the side and one at each end. The side doors can slide, as noted in the sketch, so that in winter they can be securely tightened in place, like cab doors. Two extra seats may be provided on the platforms for summer travel, which is almost always greater per car than in winter. I have paid no attention to detail, as I am not building such a car, merely offering it as a suggestion. For summer use the end doors are securely closed and the running boards are used for steps. The side doors are then fastened back or taken off. The only work involved in the alteration is the shifting of the seats. The two extra seats for the summer car would be the only parts requiring winter storage, and they can be so made that they will retain their shape in or out of use.

S. E. Clarkson.

Street Railway Park at Columbus, Ohio

THE COLUMBUS CENTRAL RAILWAY COMPANY,
COLUMBUS, OHIO, Dec. 11, 1898.

EDITORS STREET RAILWAY JOURNAL:

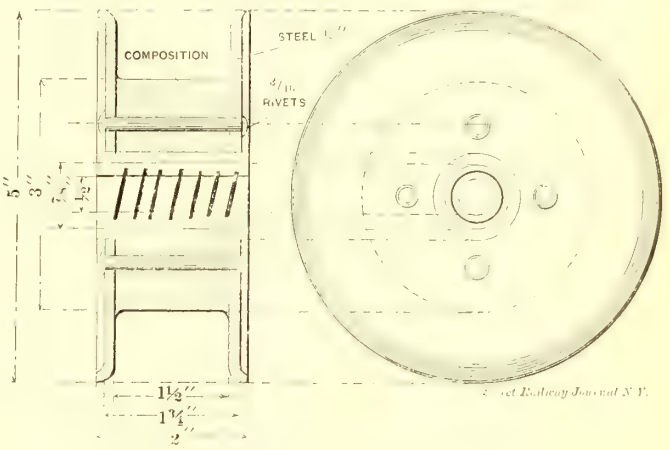
The view herewith is a flash-light photo taken of the audience at our theater, Minerva Park Casino, on the evening of Oct. 2, 1898. We consider this picture a strong argument in favor of street railway parks and summer vaudeville, which many of your contributors seem inclined to regard as at least partial failures. Without being posted on the local conditions obtaining, the price paid for artists by these gentlemen would, it seems to us, account for the failures, as performances costing $200 to $250 will not draw, while performances costing twice that amount will command in business many times the difference paid for performers.

At Minerva Park Casino we maintain an excellent orchestra of fifteen pieces, which doubles to brass for a short concert before the performance. We pay from $500 to $600 for artists, and book all acts separately, thus avoiding anything objectionable or undesirable.

We have in the capacity of amusement manager a competent theatrical man of extended experience, and book without charge attractions for a circuit of street railway parks extending from Pennsylvania to Illinois. The object of this circuit is to enable us to contract with performers for ten or twelve weeks' steady work with short railway jumps and consequent small traveling expense, at a reduction in salary of 25 to 50 per cent to the advantage of those in the circuit.

Regarding fares, we issue an excursion ticket during the summer season for 15 cents, including a coupon for admission to Minerva Park. Five cents is credited to the park for every coupon taken at their turnstiles. No admission is charged to the Casino, but we reserve 1200 seats at 10 cents and 100 box-seats at 25 cents. The balance of the house is free. The total seating capacity is about 3000. Reserved seats are on sale at the principal hotels ten days in advance.

AUDIENCE IN CASINO, COLUMBUS



Minerva Park covers 156 acres, and contains all the usual amusements. The stimulus given to business by the addition of the vaudeville greatly increases the value of the numerous concessions on the grounds.

As a further argument that summer vaudeville can be successfully run in street railway parks, we can point to Minerva Park as a railway park that is self-sustaining, and which brings in considerable traffic to this road.

F. N. BENDELARI, Agent for Receiver.

Trolley Wheel for High Speed Roads

In the early experiments in high-speed heavy electric railroading with overhead construction carried on by the New York, New Haven & Hartford Railroad Company on its Nantasket Beach and New Canaan branches, considerable difficulty was experienced in getting a satisfactory form of trolley wheel. As explained by Col. Heft in the issue of STREET RAILWAY JOURNAL for November, 1897, it was found that as soon as the speed of the cars was increased beyond a certain point the ordinary trolley wheels would jump the wire very frequently, particularly at curves. Many trolley poles were broken in this way in addition to the damage done to the overhead construction. It was also found that the wheels were very often destroyed by the almost continual arcing when taking from the wire the heavy currents required in starting and during acceleration as well as the smaller currents taken at the maximum speeds.

TROLLEY WHEEL FOR HIGH SPEED ROADS

In order to overcome these difficulties the form of trolley wheel shown in the accompanying illustration has been devised and is now the standard type on all the overhead electrical divisions of the New York, New Haven & Hartford Railroad. The wheel is made up of a cylinder of composition metal 3 ins. in diameter, and with curved edges, which fit against 5-in. steel flanges which are ⅛ in. thick and riveted through the body of the wheel. The tread for the wire is 1½ ins. wide, this large gage being employed in order to give to the wheel more play upon the trolley wire and thus prevent it from jumping at high speeds. The tread can be easily replaced when worn out without renewing any of the other parts of the wheel.

The New York Auto-Truck Company is the title of a corporation recently organized in New York to build automobile drays, operated by compressed air motors. Joseph H. Hoadley and Henry E. Knight are largely interested.

EDITORIAL NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL, *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to
The Street Railway Publishing Co.,
Havemeyer Building, 26 Cortlandt St., New York.

Street railway earnings are improving—not by leaps and bounds, but steadily and satisfactorily. The improvement appears to be general over the entire country. The great rise in the prices of "traction stocks" in the New York, Boston and Philadelphia stock markets since election day has excited widespread comment and has made bankers and brokers eager to put new enterprises upon the market—enterprises which in some cases have been shelved for several years waiting for favorable money conditions. Wall Street is full of money, full of confidence and full of daring to-day. In the vernacular of the Street, "stocks are booming" and "anything goes." It is superfluous to say that there is danger to the permanent investor at such times as this, and much discrimination should be used in sorting out the sheep from the goats. Nevertheless, the fact remains that the street railway industry of the country is in good condition, so far as earnings are concerned, and needs only a few years of continued prosperity to become favored of capitalists as a field for investment.

Americans cannot longer ignore broad world problems and responsibilities. Whether we will or not, "imperialist," or "expansionist," ideas must prevail in the long run, and no "strict construction" group of legislators or individuals can prevent it. We say this calmly and dispassionately, more as recording a prediction than as supporting a debatable policy. If the history of our own and other countries proves anything, it proves that nations are constantly broadening out in their interests and ambitions—not turning all their efforts back into the narrower grooves of self-improvement. The reflex action of a widening national policy upon the individual citizen is not the least valuable of the results which will follow. So long as Americans deal with purely national or local matters they are individually provincial. So soon as they reach around the world and grapple with international ones they become cosmopolitan. The London bus driver gravely discusses with his nearest top passenger the morning's report of Russian encroachments in Manchuria. The flower of British young manhood is winning fortune and fame in India, South Africa or Alaska. French and German capitalists examine all countries for opportunities for investment. Shall Americans, then, in proud but short-sighted self-sufficiency, say, "Our country is large enough for us?"

It would be hard for American manufacturers, and particularly for the makers of street railway apparatus, to be other than "expansionists." When the crash in prices came five years ago and home business had to be taken by our manufacturers without profit, or at a loss, the foreign markets began to be explored, at first diffidently, if not despondently. Greatly to their surprise, they found better chances for success than had been deemed possible. The high prices paid for American labor were counterbalanced by a much less rate of production per workman in foreign countries, where trades unions hold full sway, while the magnitude of our markets was, and is, such that division of labor and use of labor-saving machinery can be carried to the highest perfection, and so large a quantity of manufactured product can be turned out that much of it can overrun into other countries and be sold at a price less than the foreign cost of production with their smaller and greatly subdivided markets. As a consequence, we see enormous annual increases in the foreign shipments of American manufactured goods, which have excited the wonder of our own and of foreign statisticians, and have raised us at least to the second position among the creditor nations of the world. Moreover, it is not true, at least in the street railway manufacturing industry, that American makers have been forced to content themselves with lower prices for goods sent abroad than for those sold at home. Instead of this, materially higher prices have ruled for foreign consignment and reports of heavy price cutting and losses, circulated at home as well as abroad, are false. America has as fine a corps of selling and distributing agents in Europe as is possessed by the manufacturers of any country. We have not, however, properly and fully sought the trade of the Orient and of South America. The Philippines should be invaluable to us as a vantage point for the immense and just opening development of the Chinese Empire, for which Russia, Great Britain, Germany and France are striving. With the Nicaragua Canal constructed, with the Hawaiian Islands as stepping stones to Eastern Asia,

and with a Pacific cable binding our new possessions more closely to us, the American Empire will be firmly established in the front rank of the great world powers, and will be able, with dignity, fairness and moderation, to preserve or improve its standing, and to obtain for its citizens a rapid increase of individual and collective wealth and prosperity.

The Paris Exposition of 1900 promises to draw to that city a very large number of Americans, among whom will undoubtedly be numbered many of our readers, who will take the opportunity which the visit to Paris affords to inspect the tramway systems of France, and perhaps those of some of the other countries of Europe. The next convention of the International Tramways Union is scheduled for Paris in 1900, and Americans, who are interested in street railway enterprises here, and who expect to attend the Paris Exposition, would do well to time their visit, if possible, so as to be present at the meeting of that association. The date of that meeting has not yet been announced by the executive committee of the Union, but will be duly published in the JOURNAL when it is made public. In this connection, Mons. Lavalard, one of the managers of the General Omnibus Company, of Paris, the largest tramway company in that city, has sent us a letter in which he suggests that a congress of all the tramway companies in the world be held in Paris at the time of the Exposition, and states that he believes that a great deal of mutual benefit would be derived from such a meeting. The plan of a World's congress seems an excellent one. In spite of the differences in steam railroad practices between this country and Europe, the International Railroad Congress, held abroad, is always well attended by American railroad officials. The differences existing in electric tramway practice here and abroad are much less than in steam railroading, and, in the essential features of the mechanical and electrical sides of the subject, are practically *nil*. It is not too much, therefore, to expect good results to follow such a meeting, and what city and time are more appropriate for the first meeting than Paris and 1900?

A very large amount of the wear to which special work is subjected is caused, not by the normal, but by the abnormal, wear of the wheels. A properly proportioned wheel will not be anywhere near as destructive to special work as an improperly proportioned wheel, or one which through wear has lost its original shape. For this reason, wheel wear must not be considered as being limited to the wheels themselves, but as covering a very much wider field, and, as wheels are very much cheaper than special work, it is almost a truism to say that there is no economy in trying to get wear out of wheels after they lose their shape to any considerable extent. In other words, after they have reached a certain point, they are so destructive to track and special work, particularly when the latter is not of the hardened center type, that there is no economy in trying to save the metal in the wheel. This is one argument against the use of steel-tired wheels, which are more popular abroad than in this country. As we have repeatedly pointed out in these columns, the use of steel-tired wheels on tramways or street railways, where there is apt to be grit and dirt on the track, is an entirely different proposition than on steam railroads where the track is laid with exposed ties. With the head of the rail on a level with the pavement steel-tired wheels soon lose their shape, and while they can be run within much closer limits, so far as flange breaking and chipping is concerned, than chilled iron wheels, it is needless to say that when worn out of shape they are exceedingly destructive to the track construction. On the perfect condition of the latter hinges directly the life of the cars and motors, together with the comfort of the passengers, so that a badly worn wheel, if persistently used, is apt to produce effects of a far-reaching nature to all branches of a road's permanent way and rolling stock.

We commend to the special attention of street railway secretaries, treasurers, auditors and accountants the paper in another column on "An Ideal System of Street Railway Accounts." This is an entirely dispassionate discussion, from the standpoint of a professional accountant, of the relationship which the different classes of accounts in the profit and loss statement and the balance sheet bear to each other, and to the general accounting scheme. The key-note of the discussion lies in the statement that "the one aim of the skilled bookkeeper is to be able to produce when necessary a clear and correct final balance sheet. * * * * The ideal in bookkeeping, therefore, is a perpetual balance sheet, a balance sheet that is an integral part of the accounting system, and not something that is made up outside of the books at intervals." (In this last use of the term "balance sheet" there is included the profit and loss statement.) In other words, there is brought out in this discussion for the first time, so far as we are aware, a description of the "Balance Sheet System" of bookkeeping as applied to street railway accounting, and we heartily indorse the suggestion on its broad lines as a good one. The "Chart of Analysis and Classification" presented by Mr. Kittredge will be of great value to accountants, as it expresses the locations and relationships of the different accounts in the clearest possible manner.

The remarkable presentation in our November issue of the "Comparative Costs and Profits of Electric Cable and Horse Railway Operation in New York City" has naturally been widely noticed, and in many cases reproduced, by the engineering and daily press at home and abroad, while it has been reprinted in pamphlet form for the use of members of the London County Council and of the Glasgow Council. Many analyses and attempted applications of these figures have been made in editorial and correspondence columns, and by the advocates of different motive powers in municipal councils. The New York figures have surprised and puzzled many people, for one reason and another, and the mistake has frequently been made of trying to fit them to other conditions. Whenever startling differences in receipts and operating expenses of any two roads give rise to speculation as to causes, it is a quite safe plan to turn first to the car mileage records and ascertain the differences of practice between the roads in the matters of schedule speeds per hour, miles per car-day, use of trailers, etc. Among others, we notice in a recent number of the "Railroad Gazette," an interesting comparative schedule of the costs per car-mile of the conduit electric

system of New York, and the trolley system of Chicago, and of the cable systems in the two cities. The differences are remarkable, and, unfortunately, little attempt at explaining them is made by the author. The putting together of figures of this kind without an accurate statement of the differences in practice is a mistake from the standpoint of the true statistician, since wholly incorrect deductions may be drawn by the ill-informed, and action may sometimes be taken involving the gravest financial consequences from mere impressions given by such figures. How can New York and Chicago results be compared? In New York no trailers are used on either grip or electric cars, while in Chicago a grip car carries from one to four trailers, according to the time of day, thereby saving greatly in power consumption and in transportation expenses per car-mile; the schedule speeds per hour in the two cities are quite different, which affects both transportation expenses and power; the time interval between cars on the Broadway system is so short that the load and wear upon its cables are terriffic, thereby causing an expense for renewals of cable alone amounting to 20 per cent more than the entire maintenance of way expenses of the Chicago City Railway Company; transportation wages per hour are different in the two cities; electric cars are mostly long in New York and short in Chicago, and, finally, many of the expenses are functions not of car mileage, but of miles of road or gross receipts. The car-mile unit for comparison is extremely fallacious and misleading—the ton-mile unit, when possible to obtain it, far better.

The increasing unwillingness of municipalities in Europe and America to grant any but short-time franchises or renewals of franchises to their street railway companies is deplorable, from almost every point of view. Granting that the public should derive the greatest possible benefit, in one form or another, from the use of its streets for transportation purposes, it is yet always possible to arrange compensation over a long term of years on some sliding scale, such that this desirable end can be obtained without, on the other hand, forcing the street railway companies to borrow money at high rates or to have their securities regarded as unstable. It is always to the advantage of the municipalities, as well as of the companies, to have the former's securities regarded as low rate—4 per cent, for example—investment, but a short tenure of franchise or any other element which makes the immediate future uncertain tends to raise the rate of interest demanded by capital, and therefore reduces the concessions which can be made to the public in the way of improved service, extensions, etc. The English plan of twenty-one-year franchises has worked so wretchedly by emasculating enterprise and retarding the growth and expansion of cities, that the object lesson ought to be taken to heart by well-informed Americans. On the other hand, the magnificent enterprise shown by private companies in those places, in America, particularly, where franchises have been granted for long periods, is an object lesson of the other kind. Does any one suppose the New York City street railway companies would have spent $30,000,000 to $40,000,000 in the adoption of the cable and electricity, or would have instituted their almost universal transfer system and improved their cars and car service so tremendously had their franchises been granted but for twenty-five, or even fifty, years, instead of in perpetuity? Or would the City of New York itself, had it owned its own railways, have grappled with the city's transportation needs and problems in so bold and far-seeing a manner? No. The "debt limit" scare, or the fear of showing a temporary deficit would impel politicians at the moment in charge of the city's development to look to the present, rather than the future, and the "conservative" element would prevail. We have little need to cast our eyes over the water to British cities, which own their tramway systems, to see how true this is, and how impossible it must be for large bodies of elective trustees of the public interests, such as the London County Council, to act promptly or in a broad-gage manner on the most urgent problem with which they have to deal, that of providing a centrifugal force, in the form of transportation facilities, for throwing their populations farther and farther away from their congested districts.

* * * * * * *

In Chicago, we are just now seeing the beginnings of a retrogressive action, which may be one of the most disastrous calamities which that city can suffer. A young man, with an ambition for high political preferment, is Mayor of the city. It is openly alleged, and so far without contradiction, that he has entered into an agreement with all but one of the prominent daily newspapers of Chicago, by which he is to assist them in their efforts to "hold up" the great traction companies of Chicago for large sums of "hush money," in consideration of their support of himself as candidate for another term as Mayor, and eventually for higher office. In pursuance of this alleged agreement, the Mayor and these newspapers of Chicago are working together in every conceivable way to excite the people against the companies, and to prevent the passage of an extension ordinance in the council. These newspapers are refusing the companies a hearing in their columns. They have actually, in times past, refused to publish the text of the legislative bills which they have been fighting, even when the street railway companies offered to pay them for such publication at regular advertising rates. The companies have been forced to reach the public through the one newspaper independent of the "combination," and by circulars in their own cars. Mass meetings have been called, and threats of violence against the Aldermen, in case they vote for the measure, have been freely made, and the Mayor—an officer, sworn to uphold the law and to preserve public order—has intimated in public that he would not be disposed to call out the city's protective forces to prevent such violence. To the credit of the public of Chicago, it should be said that their love of fair play appears to have caused them to resist to some extent these inciting influences. Mass meetings appear to be not "overflows," by any means, and one instance is recorded of a mass meeting attended by four people only, who passed "without a dissenting voice" (as the combination papers said the following day), a vote declaring for municipal ownership!

Some Facts and Probabilities About Interurban Electric Railroading

The interurban electric railway system around Detroit, an extended description of which is published in this issue,

is a good example of a branch of electric railroad work in which comparatively little has as yet been done. Outside of the interurban electric railways around Cleveland and Boston, there is no system in this country which can compare in extent to that around Detroit, and, of course, there is none in any other country. It is difficult to say to what length these interurban electric railway projects can be carried to advantage. Those in the neighborhood of Detroit already reach out, in some instances, a distance of about 40 miles from the city, and nearly all of them are from 20 to 25 miles in length, while a railway from Detroit to Toledo is already under way, and appearances are that it will be completed. The roads around Boston, to which reference has been made, differ materially from those around Cleveland and Detroit, in that while as long trips in a direct line can be made on electric cars, the system is made up for a large part by the lines of separate companies, which bear a closer resemblance to the ordinary city or village railway than in the case of Cleveland and Detroit. In these last cities each radiating line is operated as a unit, the cars are long, resembling in appearance steam railroad cars, and more of an effort is made for through business than in the case cited in New England. It would seem as if these roads are prototypes of extended electric systems which will spring up around large cities, or between smaller towns, where there is a sufficient number of inhabitants along the route to develop traffic, and the effect of these lines on steam railroad traffic, while comparatively small in individual cases, must in the aggregate amount to considerable. It has been shown that with the saving which these lines can effect by building along the line of the highway and in the cheap subdivision of power possible with electricity, passengers can be profitably carried at an average rate of about a cent a mile, a figure which seems impossible under present conditions with steam railroads. The latter already recognize a dangerous competitor in electric railroads for this short distance traffic and are doing their utmost to suppress it; but it is a condition, not a theory, which confronts them, and if electric roads can be built and operated at these low fares, village and town authorities will find some way of granting them the necessary franchises.

In some, in fact, in a great many respects, the interurban railway proposition is an attractive one, especially to those railway owners and managers who have had experience with city properties. In the first place, the question of franchises is usually much simpler than with city railways, in spite of the fact that concessions have to be secured from a greater number of municipal or other governing bodies. The reason of this lies in the fact that (a) the abutting property owner is benefited to a greater extent, or "injured" to a less extent, by having the railway in front of his property than in the case of city roads, as esthetic objections to the overhead wires do not trouble him, there is less noise from the railway traffic, and it gives him direct means of transportation at his door; and (b) the community, as a whole, welcomes a transportation agency which is always more convenient and cheaper than that which existed before. In the second place, the franchises are usually for definite and longer periods and are less apt to be reviewed by common councils with a change of administration. In the third place, the ability to run at high speeds offers a continuous opportunity to reduce transportation charges, while the traffic on such a road has nearly always as great possibilities of development as the city railway without as much danger of competition. In the fourth place, many of the mechanical problems which make the life of the city manager a burden and keep him awake at night disappear in the interurban railway. One of the most important of these is that of track, which can be built according to steam railroad standards with exposed rails and ties, on which joints can be watched and bolts kept constantly tight, without continuous pavement excavation. Many problems connected with interurban electric railroading yet remain to be solved, but, taken as a whole, they do not seem to be any greater than those connected with city railway service, even in its present development, and there seems little chance that any radical changes will be effected.

In one respect, interurban electric railroading as practiced in this country seems to have taken a direction which has somewhat surprised owners of similar projects abroad, and that is the universal employment of the continuous current for transmitting power and for use on the line. In another article in this issue we print an extended description of an interurban railway in Switzerland, which is considerably smaller in extent than very many in this country, but on which the alternating current motors are employed. The author of the article, M. Charles Rochat, who has charge of the engineering branch of the Railway Department of the Swiss Government, in reviewing the application of 3-phase currents on this road, takes occasion to point out certain defects in alternating current motor work. One of these, that of constant speed under all conditions, does not seem to be unsurmountable. The use of two trolley wires is certainly a drawback, for while most of the single-track interurban railways in this country employ two trolley wires, they do so for the sake of avoiding switches at turnouts, and with the 3-phase system, if overhead switches are to be eliminated, four overhead wires would have to be used. Evidently the possibilities for trouble in the use of polyphase currents for traction work and the comparative newness of this branch of the work has so far discouraged railway managers in this country from taking it up. The continuous current motor has reached a high state of development. Its defects, though numerous, are all known and tend to decrease with the size of the motor and with time. The only immediate saving in the introduction of the alternating system would be in reducing the size of the feeders, and, as we all would

> " Rather bear those ills we have,
> Than fly to others that we know not of";

the continuous current is likely still to remain a favorite, especially as, with the use of boosters and from 600 to 650 volts on the trolley wire, the feeder cost can be kept down considerably below that required by current city practice.

Electrical improvement has cost individuals and communities large sums of money, but it has in every case produced more than the cost; and it has been cheaper to have these improvements than to do without them. This fact cannot be questioned, and the isolated cases of failure in practical experiments or poorly calculated investments are but the sacrifices by which the general good has been gained. I think I may venture the statement that the electrical industry has produced more changes in the mechanical service and convenience of civilized life than has ever been caused by the application of any other force subject to the service of man.—From paper read at the Montreal Convention, 1895.

An Ideal System of Street Railway Accounts *

BY A. O. KITTREDGE, F. I. A., C. P. A.

One of the most eminent authors of modern treatises on accounting says: "The object of all good bookkeeping is the exhibition of the growth or decline and present value of capital, and of each of the parts of which capital is made up. A perfect balance sheet shows all this in the clearest and most concise manner. A perfect balance sheet should not only give the present value of each of the component parts of capital, but should also indicate its growth and decline since the last statement. The one aim of the skilled bookkeeper is therefore to be able to produce, when necessary, a clear and correct final balance sheet."

From this we derive inferentially that the more frequently a balance sheet is made up, the more thorough is the showing with reference to the condition of the capital, its growth or decline and its distribution in different places. The ideal in bookkeeping, therefore, is a perpetual balance sheet, a balance sheet that is an integral part of the accounting system, and not something that is made up outside of the books at intervals. In this last use of the term "balance sheet" there is included a profit and loss statement. A balance sheet, so arranged as to be an equivalent, for example, of the cash account, and which, through the medium of its divisions, shows the growth and development of the business in all its branches, just as the cash account shows fluctuations in the cash on hand, is a desideratum worth striving for. On the other hand, a perpetual profit and loss statement, which shall show the relation of expenses to earnings in all proper detail, is also something well worth the effort required to secure it.

The analysis of accounts, which it is the purpose of this article to describe, and which is herewith presented in chart form, is that which is required where the balance sheet is made an integral part of the bookkeeping system and where the profit and loss statement is made perpetual and also a going part of the bookkeeping system. What is shown is no new or untried scheme. It is something that is now in successful use in some hundreds of enterprises throughout the country and something that has been found entirely satisfactory in various lines of business, from that of transportation companies to banking, from manufacturing enterprises to mercantile houses, and from the largest jobbing concerns down to small retail establishments. The universal success which the application of this plan of analysis has met, wherever tested, warrants its presentation to the street railway accountants of the country. That its application requires some books of peculiar construction and certain mechanical facilities which it is not the purpose of this article to describe, should not in the least detract from its interest. Suffice it to say in this connection that whatever is special in this regard is far less in amount and expense than the necessary equipment of various other improved methods used every day in offices of street railway companies, as well as in other directions.

At the outset it is only right that attention should be called to certain divisions or elements recognized in the chart, which to some accountants, who have not had a broad experience, will appear strange and unusual, and yet the function of each of these, it is believed, will be made clear as the explanation proceeds. Again, it should be remarked that in describing an ideal system it is necessary to include more in items and detail than perhaps ever would be employed in any individual case. The system, to be adequate, must be exhaustive in its presentation, leaving to the individual user the privilege of selection and adaptation.

All the accounts of a street railway company, as well as of any other business, are comprised in two general classes —namely, the accounts of the balance sheet and the accounts of the profit and loss statement. It is impossible to conceive of any account that will not properly fall under one or the other of these heads.

Referring now to the chart, it will be seen that the accounts of the typical overhead electric railway company are presented in these two grand divisions—first the balance sheet, and second the profit and loss statement. The balance sheet divides under the two heads commonly recognized in a document of its kind—namely, into assets and liabilities. The assets of the company, by their nature, may be divided into three classes—namely, active, fixed and passive. These terms, by the way, are optional, and others, perhaps still better in definition, might be substituted. The point is not the special names that are employed to designate classes, but the classes of the accounts in themselves.

The active assets comprise cash, the term being inclusive and embracing the amounts in the office safe and in each of the several banks in which deposits are made; notes receivable, accounts receivable, sub-divided as required, and materials and supplies, represented by such accounts in name and character as are appropriate for the purpose.

The fixed assets, as presented by the chart, are largely those designated by street railway accountants as construction and equipment accounts. This term, however, seems to be insufficient for the purpose, and therefore I have preferred the term "fixed assets," dividing under that head into two classes, the first called necessary investments and the second other investments.

The necessary investments, going back to the organization of the company, include the cost and expense of its charter and its franchise and the expenses of preliminary engineering, etc. Following this are the items properly falling under the head of way and structures, and also under the head of equipment. Way and structures subdivides into right of way, track and roadway, electric line, real estate used in the operation of the road, buildings and fixtures, being the items *B* to *G* inclusive, of the construction and equipment accounts, as reported by the committee on standardization at Boston.

Right here I desire to remark that throughout this classification of accounts I have held, so far as possible, to the terminology suggested by the committee on standardization, and have used their list almost complete. I have found it necessary, however, to make radical changes in location, so far as one or two accounts are concerned, the particulars of which will appear hereafter. In this connection the reader's attention also should be directed to the fact that in the chart the accounts suggested by the committee on standardization have been printed in different type from the balance of the chart (cap italics) and are further indicated by the letters and prefix numbers as reported by the committee.

Equipment divides into power plant equipment, shop tools and machinery, cars, electric equipment of cars, and miscellaneous equipment, being items *I* to *M* inclusive, of the construction and equipment accounts, already referred to.

Two single accounts of this class have been omitted—namely, *N* and *O*. These are "interest and discount" and "miscellaneous." The explanation of the former, as offered by the committee, is that "all interest paid or received in connection with funds for construction, and all discounts or premiums resulting from a negotiation of securities for

*Copyright, 1899, by Account, Audit & Assurance Co., Ltd., New York. All rights reserved.

construction, should be charged or credited to this account." With respect to the second, miscellaneous, the following explanation appears: "Charge to this account all expenditures for printing and stationery, office supplies, damage claims, wages of clerks, and all other expenses incident to construction not otherwise provided for." Evidently what is in mind with respect to these two accounts is that they shall include the expenses in connection with the construction and equipment of the road that are specified in the explanatory notes. The items named are parts of the cost of the assets represented in the chart by the accounts *A* to *M* inclusive, although I cannot see that they are assets in themselves. The accounts *A* to *M* represent tangible assets, whereas *N* and *O*, as above described, do not represent assets, but are parts of the cost of assets otherwise designated. Therefore, it would seem to me that the items included in *N* and *O*, instead of existing in the balance sheet as separate accounts, should at the outset be pro-rated among the accounts *A* to *M* inclusive. An expense item in the capacity of an asset is an absurdity in bookkeeping, although there are several illustrious precedents of such classification.

Other investments include, in addition to item *H*, investment real estate, of the list just alluded to, stocks of other companies, and bonds of other companies. Whether or not a given company at present owns securities of other companies, it is necessary in a scheme of analysis such as we are considering, to show where such accounts would fall, in case they were required to be opened.

By the passive assets of a company I attempt to indicate those which are not permanent in character and which are to be written off sooner or later. Under this head fall some of those items which before now have been the distress of many an accountant—for example, the accounts which must be opened to offset excessive capitalization. Good will, a convenient and elastic name of an account to which is usually charged whatever cannot be properly laid upon the tangible assets of the concern, is an excellent illustration. By items in suspense are meant accounts carrying amounts of an expense character paid in advance of their consumption in the operations of the company. In a recent article in these columns I have discussed suspense items so thoroughly that further description is not necessary at this time.

The second grand divisions in the balance sheet—namely, liabilities—divides into four classes. First come the funded debts of the company, such as first mortgage bonds, second mortgage bonds, debentures, etc. Next comes the floating indebtedness of the company, including such items as notes payable, accounts payable, subdivided as required, and dividends which have been declared, but which for the time remain unpaid. Accounts of this kind are occasionally required to be opened, but for the most part they are closed almost as soon as opened. This item in the chart is only to show the location of such accounts.

Next in order come the reserve accounts, a class of liabilities occupying middle ground between what the company owes the public under the heads of funded and floating indebtedness and what it holds in trust for its stockholders, so to speak, for certain specified purposes. The reserves enumerated in the chart are quite as many as are likely to be required in any company, and yet possibly omissions will occur to the reader, and not a few will suggest substitutions. Many are likely, perhaps, to declare some of the accounts named entirely unnecessary.

First, there is the reserve for taxes; following which is the reserve for interest on funded debt, and on the floating debt as well. Next there are the reserves for the several sinking funds necessary to retire the funded debt; following which are the reserve accounts for maintenance and depreciation, each divided into two classes—way and structures, and equipment—and, finally, the reserve to establish an emergency fund out of which to pay damages, accidents and losses from the destruction of the property.

In a recent article in this journal I have described the theory of reserve accounts, introducing illustrated examples, so that extended remarks on this subject are unnecessary at this place. Suffice it to say that the theory upon which this chart proceeds is that monthly costs shall include an allowance for each of these items. The books that this chart exemplifies are the books of the stockholders exclusively, not of the bondholders, nor yet of the public. Interest, taxes, maintenance, depreciation and emergency costs must all be met before the stockholders are entitled to a dividend. Costs on each of these items, properly pro-rated, are charged up month by month, as the profit and loss statements show, and the proper reserve accounts credited. When the time for payment of any of these costs arrive—for example, when taxes are due, or when interest is due—the reserve account is charged with the amount instead of the expense account, for the expense account has already borne the charge upon the monthly pro-rata basis.

Some of my readers may take exception to the provision that is indicated of reserves for sinking funds, and they may more particularly object to the charges forming the reserve being regarded as a part of the expenses of the road. It is to be remembered, as just mentioned above, that the point of view from which we are discussing an accounting system is that of the stockholder. The showing to be made by the balance sheet and profit and loss statement is that in which the stockholder alone is interested. The resultant profit that is shown is that which is available for dividends, all charges of whatsoever name and kind having been previously provided for.

There are several points of view from which a sinking fund may be considered. Where an enterprise is "property rich" and "cash poor," a sinking fund to provide for the retirement of bonds may be created out of assets through the process of reserving from time to time a certain percentage of the cash that is received as its property is sold. That, however, is not the position in which street railway companies are ordinarily placed.

An individual, a business firm, or a corporation borrows money to use in business, primarily because the business requires more capital than the owner can supply. Theoretically, at least, the loan is negotiated with the expectation of paying it off at maturity. It can be paid when it falls due in only one of two ways, leaving out of the account for the moment the special conditions occasionally prevailing in certain classes of enterprises just referred to above. One of these ways is to take up the original loan by negotiating another loan—that is, retiring one set of bonds by the proceeds of another issue of bonds. The second plan is to reserve enough out of the profits of the enterprise to meet the bonds when due.

I venture to suppose that there are some who read this who will say that to pay off a loan, that is to retire mortgage bonds, for example, out of profits, is an absurd idea of financing at the present day, particularly when money can be borrowed at the low rates of interest which prevail whenever good security is offered. Even so, yet the accountant, not acting in the capacity of a financier, must show, in any scheme of accounting that is intended to meet all possible requirements, how to proceed whenever the stockholders determine that the bonds shall be retired out of earnings, in order that their shares may correspondingly appreciate in value.

Some who give consideration to this subject may be disposed to argue that the increasing value of the company's property by reason of the growth of population and general development of the community through which the road runs, is in itself a sinking fund adequate for all purposes. To this the accountant, in turn, is disposed to give a strictly professional answer, namely: Do not let one thing offset another, in the belief that thereby a balance is effected, but put a proper valuation on each item, both debit and credit. Let every tub stand on its own bottom, at all times.

Whether or not a sinking fund shall be created and maintained is to be decided by the management—not by the accountant. The chart shows how to proceed where a sinking fund is decided upon, and is to be built up out of earnings at a fixed rate.

Finally, we come to the capital division of the liability portion of the balance sheet. It is divided into three heads —profit and loss, impairment and surplus, and capital stock. Profit and loss, as here shown, may be defined as capital in process of accumulation. It is subdivided into weekly, fortnightly, monthly, quarterly, semi-annual and annual accounts. Profit and loss account, as here placed, is the resultant and not the active account. Referring for the moment to the profit and loss statement, it will be seen that expenses and revenues are there contrasted. The difference between expenses and revenues weekly, if the accounting is arranged on a weekly schedule, would make the weekly profit and loss account in the balance sheet statement. If the profit and loss statement be run upon a monthly basis, then its showing would make the monthly amount in the balance sheet, and so on.

Assuming that weekly closings are being made in the balance sheet ledger (one of the special devices referred to at the early part of this article), then the weekly profit and loss account, as the weeks roll on, would be closed into the monthly profit and loss account, and the monthly, in turn, according to the preference of the management, would be summarized into the quarterly, or the semi-annual, or the annual. Each basket would be emptied as soon as filled, to be ready for the next use.

If dividends are being earned and declared, profit and loss, quarterly, semi-annually, or annually, as the case may be, would be charged with the amount of dividend declared. Any amount remaining in the semi-annual or annual profit and loss account would then be carried one step further to the credit of impairment and surplus account.

If the business is running at a loss, then the closing of the semi-annual or annual profit and loss account, as the rule may be, would be to the debit of the next account in order—namely, impairment and surplus—in a way to show an impairment of capital. Capital stock account remains a fixed quantity, either in a single amount or subdivided into common shares and preference shares, as the organization may be.

In what has preceded I have anticipated much that might be said with respect to the second grand division of the accounts—namely, the profit and loss statement. The profit or loss of any business is determined by contrasting the revenues with the expenses. Since expenses must always be borne before revenues are secured, this division is given first place in the exhibit. The expenses of a street railway company are fairly classified under three heads—namely, transportation, general and maintenance. Transportation divides into operation of power plant and car service. The subdivisions opposite each of these heads are those which have been established by the committee on standardization. General expenses have been classified under four heads—administrative, emergencies, taxes and fixed charges. The accounts opposite administrative are the same as those established by the committee on standardization. The accounts opposite emergencies are likewise the same as established by the committee, with the exception of one added at the bottom—namely, accidents and destruction of property. Fixed charges are divided into interest and sinking funds. If interest is paid, it would properly fall in this class. We have already discussed the question of sinking funds, which would belong here under certain conditions. Maintenance divides into two heads—repairs and depreciation. Each of these subdivide into way and structures, and equipment.

The theory upon which this accounting system is based is that expenses shall be charged to proper accounts as they occur, so far as possible; hence the presence in the expense schedule of accounts Nos. 10 to 39, inclusive, as formulated by the committee on standardization. Where an expense is incurred which it is impossible to pay at the time, it is still charged in and the amount credited to the proper reserve account; hence the presence under the head of reserves in the balance sheet statement, of accounts 1 to 9, inclusive, of the committee's schedule. An allowance for both repairs and depreciation of way and structure and equipment should be charged into expenses week by week, or month by month, as time goes on. Since this expense cannot be paid always when it is charged in, the reserve accounts are brought into play for holding the amount until such time as the repairs can be made, or the depreciation offset by renewals. All this, however, as before mentioned, has been discussed in a previous article, and therefore does not require extended remarks at this time.

The revenues of a street railway company proceed primarily from operation, and secondarily from various other sources. These are enumerated under appropriate heads in the lower part of the profit and loss statement. How revenues and expenses are contrasted by closing all the accounts shown in the profit and loss statement back into weekly or monthly profit and loss in the balance sheet, according to the time schedule upon which the accounting system proceeds, has already been mentioned. In the arrangement of the accounts in the balance sheet ledger provision is made for this periodical closing, thus establishing the record of the results of the business at frequent intervals.

The accounting scheme here outlined dispenses with inventories, save only as inventories are taken to verify accounts. Material and supplies are charged out as used, taken at cost prices. The balance in the account of each kind of material and supplies, therefore, should show the amount remaining on hand. An inventory, therefore, would prove the accuracy of the account.

There is no line of business which I have investigated, wherein the conditions are so entirely favorable to a perpetual balance sheet and a going profit and loss statement, as a street railway operation.

Street Railway Blanks and Forms

Late in November a circular letter was issued by W. B. Brockway, secretary of the Street Railway Accountants' Association of America, referring to the new work—namely, collecting blanks and forms—which is to be undertaken by the organization named. This is described as a new departure, and one which is believed will add to the usefulness of the organization, and make it a source of practical value to every member. It will be recalled that resolutions were passed at the Boston convention requesting every member to furnish the secretary with two copies of each and every blank and form in use upon his road, and

as rapidly as any new forms are issued, two copies of the same. Notice is given that the secretary is now ready to take charge of these forms, classify them and put them in shape for exhibition purposes and general use by the members of the organization.

It is intended that these blanks and the annual exhibition of them shall be held strictly to the members of the organization. Each one contributing, therefore, is assured that whatever blanks are supplied will be used solely for the benefit of the members of the association. It is pointed out in the circular that any member desiring to get up a form for any particular purpose, will be greatly assisted by having at his disposal hundreds of blanks pertaining to the subject which he has under consideration.

The following directions are embodied in the circular: Do not fold the blanks more than absolutely necessary; rolling is preferred. Write in ink the name of the company upon all blanks, where the name does not appear. In case the blanks do not indicate clearly their use, they are to be accompanied by a synopsis of what they are intended to accomplish. The term "blanks and forms," it is explained, is intended to cover everything used by a company, including specially ruled books and tickets. The packages are to be addressed to W. B. Brockway, secretary, 106 Summit Street, Toledo, Ohio.

A CORNER OF THE KREMLIN

CHURCH OF VASSALI BLAJENNY, NEAR THE KREMLIN

Proposed Electric Tramway System in Moscow, Russia

The City Council of Moscow is proposing to grant franchises for an extended system of electric tramways in that city. The City Council has appointed a committee, of which Chief Engineer A. A. Semenoff is chairman, to consider the reconstruction of the existing horse car lines and their equipment with electric power and upon plans prepared by Technical Engineer A. A. Lineff. It is thought that the matter will be settled Jan. 1, 1899, and that soon after that preliminary work can be undertaken.

The general conditions which the council will make for the construction of the electric tramways are briefly as follows: On all existing lines electricity is to be introduced as motive power, and the system, which now has a length of 100 km., will be increased to 135 km. A very substantial construction will be insisted upon, and the gage will be 1 m., instead of the present 1.52 m. Double tracks will be made obligatory, and the speed of the cars will be limited in the center of the city to from 10 to 12 versts (10.7 km. to 12.8 km.) an hour, beyond Sadovaia Street to 15 versts (16 km.) per hour, and beyond that 18 versts (19.3 km.) per hour. The cars in the center of the city will run on the headway of three minutes. In most parts of Moscow the trolley system will be adopted, but where this is not permitted the cars will run either by storage batteries or on the surface contact system. The cars must be lighted and heated by electricity.

The fares are limited to the present 5 copeks, for which passengers are entitled to transfers to the crosstown lines, and commutation tickets will be sold. The running of freight cars will be permitted at night, and in winter cars for the removal of snow and in summer for that of dirt and refuse will be operated.

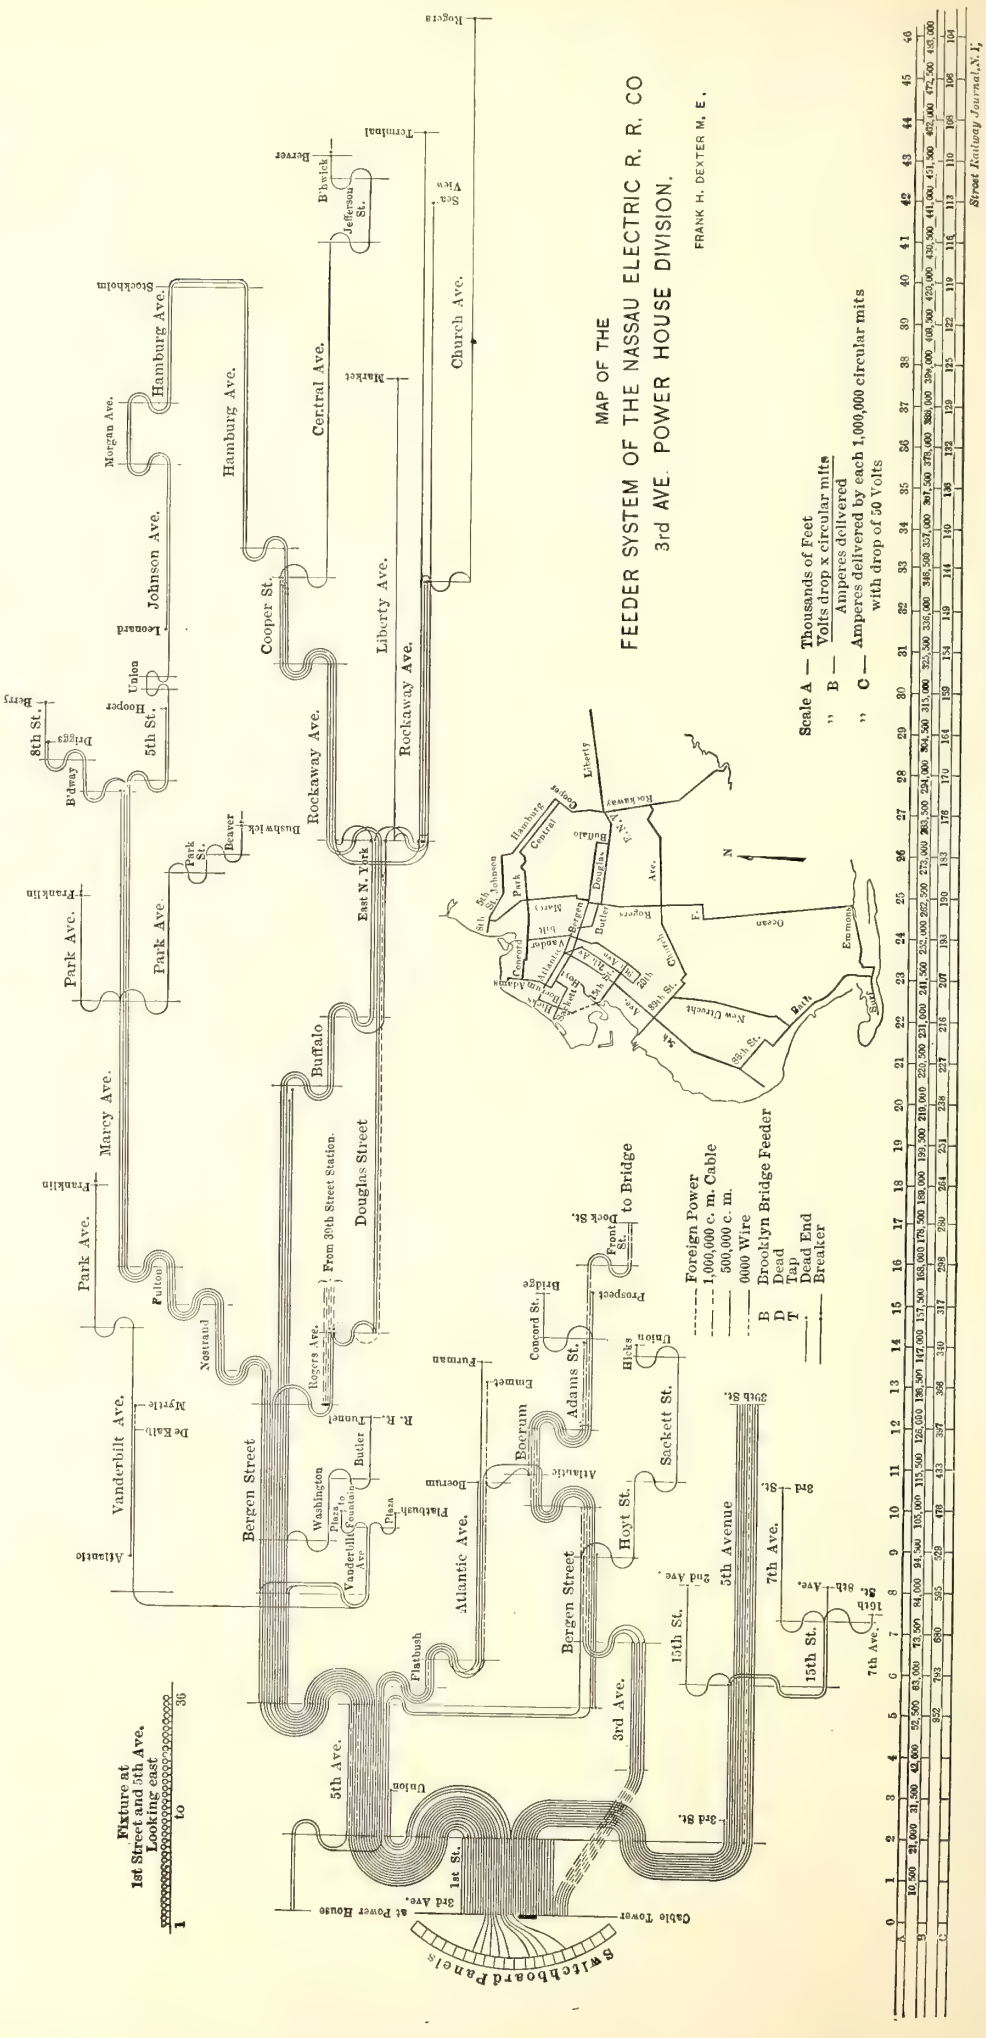
The time limit placed upon the reconstruction of the lines is four years. During the first year 28 versts must be reconstructed, and during the remaining three years 35 versts each. The lines in the central part of the city will be the first to be equipped. The change must be made without interfering with the present system of transportation. The entire cost is placed at from 15,000,000 to 18,000,000 roubles.

Current will be taken from a central power station, which will also distribute electricity for lighting. The city selected for this station is on the bank of the Moscow River, on the so-called Salt and Vinnoy yards. The builders must deposit satisfactory bonds to guarantee the completion of the work.

The STREET RAILWAY JOURNAL is indebted for the foregoing particulars to the kindness of Mr. Lineff.

A New Feeder Map

BY FRANK H. DEXTER, M. E.



In some recent work in mapping the feeder system of the Nassau Electric Railroad in Brooklyn, the common method of laying down the wires on a map of the city was found so entirely unsatisfactory, owing to size and complexity of the system, that it was found necessary to adopt some new plan. To meet this requirement the writer devised a method which trial has proven to possess a number of advantageous features.

A map of the Third Avenue Power House Division of the Nassau system, made by this method, is shown on this page. The portion represented contains 1,000,000 lbs. of copper, which deliver, at full load, 7000 amps. to one hundred odd miles of trolley wire.

Each feeder in the system is represented on the map by a straight line parallel to a common base, and each portion of a pole line, contained by a single street, by a group of such lines. On the base line is laid off the scale of lengths adopted for the feeders. Turns are indicated by offsetting consecutive groups by a convenient distance, and to the right or left, according to the direction of the turn represented. Corresponding points of each wire are connected by suitable curves in such a way that each feeder becomes continuous from the station to its end. Since the offsets are made in a direction perpendicular to the scale, the length of the curved connection is immaterial.

In our system each wire has a distinguishing number taken from the pin it occupies on the First Street pole line where it leaves the station. With few exceptions it was found convenient to lay down the wires in the order in which they appear on the pole line; where this was not the case the pin numbers are shown on the map. Jumpers, breakers, feeding points, etc., may be shown with facility. Various sizes of cables are given distinguishing colors in the original map and by lines of different character, as dotted, dashed and solid in the engraving.

Considering the complexity of the Nassau system, it seems unlikely that the special features of any other would present any seri-

ous difficulty in carrying out the general plan described above.

By thus mapping as parallel all streets traversed by the feeders, and omitting all others, much is gained in the way of compactness, for it will be seen that, whereas the area of a common map is proportional to the square of the linear scale, that of the new form varies as the first power. Then too the convenience of being able to read at a glance the distance between points on the system is not to be regarded lightly. Information of this nature is constantly in demand for various purposes. The time saved, to say nothing of the accuracy gained, by reference to the linear scale compared with that required for reference to the tabulated data (which never contains the points concerned) or of stepping off with dividers (or a string) on the city map, is considerable.

Not less useful are the scales *B* and *C*. At every point on the line there exists a definite relation between the current flowing, the drop from the station to that point, and the size of the conductors. If *P* = the resistance of a mil foot of copper we have, as the total resistance of the conductor,

$$R = \frac{P \times \text{dist. in ft.}}{\text{cm. in conductor}} = \frac{\text{volts drop}}{\text{amps. flowing}}$$

$$P \times \text{distance} = \frac{\text{drop} \times \text{c.m.}}{\text{amps.}} = \text{drop} \times \text{cir. mils per amp.}$$

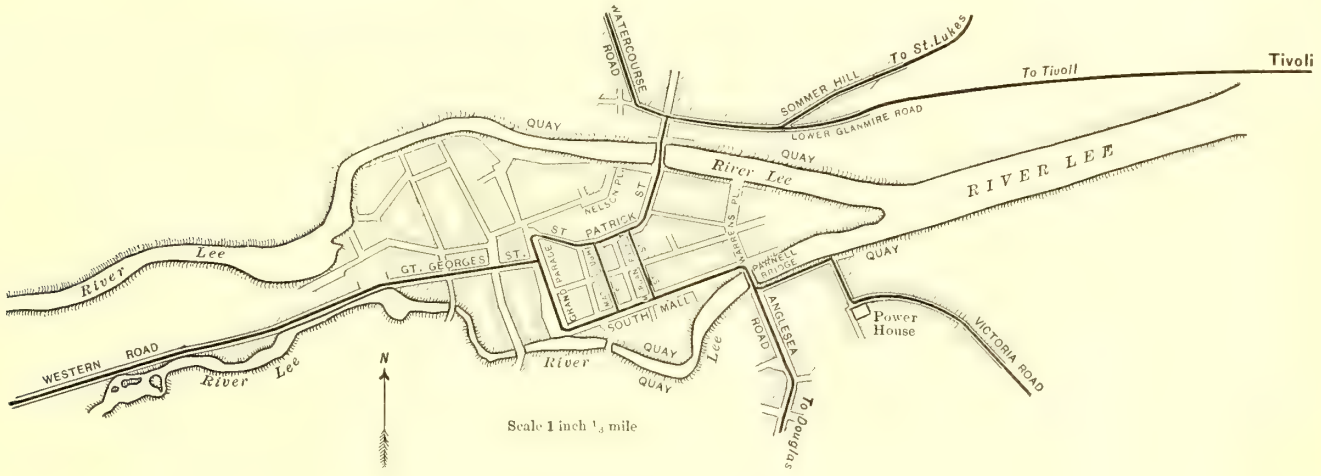
Values thus obtained are platted in scale *B*. If at any point two of the terms involved are known the third may be determined by substitution.

If it be desired to find the current delivered with a specified drop a special scale is more convenient than the general one, *B*. Scale *C* gives the number of amperes delivered with a drop of 50 volts by each 1,000,000 c.m. As before,

$$R = \frac{P \times \text{distance}}{\text{c.m.}}.$$

or

$$\text{Amps.} = \frac{\text{drop}}{R} = \frac{50 \times 1{,}000{,}000}{P \times \text{distance.}}$$



To find the current delivered by M c.m., the values of scale *C* are multiplied by

$$\frac{\text{M}}{1{,}000{,}000}.$$

Electric Tramway System of Cork, Ireland

The tramways in Cork have been recently equipped with electric power, and a general map of the system is given on this page. As will be seen, the street railway connects the center of the city, which is on an island formed by two branches of the River Lee, through the principal streets, with suburbs. The longest branch is to Douglas, a village about 2 miles south of Cork. The tramway crosses the river twice, once over Parnell Bridge, a steel swing bridge, second over Patrick's Bridge, built of stone.

The rails in the city are laid on a bed of concrete, and the roadway is paved between the rails and for a distance of 18 ins. on each side. Outside of the city boundaries the concrete is replaced by creosoted ties, 6 ft. x 4½ ins. x 9 ins. The rails are of girder type, weighing 83 lbs. per yard, with fish-plates 26 ins. long, weighing 56 lbs. per pair. The tie-bars are of wrought iron, 2 ins. x ⅜ in., weighing 10½ lbs., and double screwed at ends. The rails are fixed to the ties by thirty dog spikes and fourteen fang bolts and chips to each rail length. The switches and frogs are cast steel, made by Millar & Co., and Dick, Kerr & Co., Ltd.

MAP OF CORK TRAMWAYS

The rails form the return circuit, and are electrically connected at each joint by two No. 000 B. & S. Chicago bonds, 35 ins. long. At every switch or crossing there are two 13-ft. bonds spanning the steel casting, and there are also for each point of this kind four 35-in. bonds, connecting the rail with the casting. At each crossing there are four No. 000 B. & S. 35-in. bonds. The rails are cross bonded every 240 ft., and where there is double track, the two tracks are also cross bonded every 240 ft. These track cross bonds are placed half way between the rail cross bonds.

Where the double track is equipped with center poles the cross bonds between the two tracks are 7 ft. long, and where it is equipped with side poles they are 5 ft long. All the cross bonds on single track are 42 ins. in length. In all the loops on the single line there is a cross bond between the two tracks.

The return circuit is continued over the river at Parnell Bridge by four 0.5 in. cables, connected by bonds to the rails on either side of the water, this arrangement being necessary to avoid any interruption in the circuit when the bridge is swung open.

Center poles with double-bracket arms are used in principal streets, and side poles with single-bracket arms are employed on rest of line. Span wire construction has been installed in only a few places. The poles are 31 ft. long and

are composed of three sections. The joints are overlapping, and the sections are shrunk on while hot.

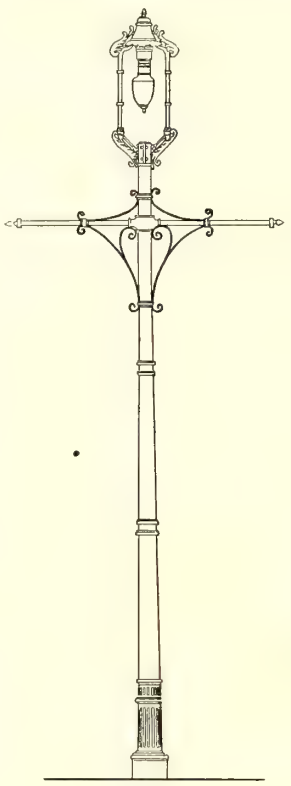
In the principal streets an arc lamp is fixed on every alternate pole. These lamps are of the inclosed arc type, connected up five in series; but consecutive lamps are not put on the same circuits; thus every other of ten consecutive lamps are on one circuit, while the remaining five are on another. The switches and resistances for the lamps are contained in the bases of the poles, so that, if necessary, a resistance can be placed in the circuit instead of a lamp. Each circuit can also be controlled from any lamp in its circuit.

The trolley wire is of hard-drawn copper and is double throughout. The portion of the trolley wire over the swing part of Parnell Bridge is supported on special poles and brackets fastened to the movable part of the bridge. The connections on the trolley wire are heavy spring clips, which allow the bridge to be moved in either direction.

The power house is situated in Albert Street, 220 ft. from the river. The building is of brick, with pile foundation.

The boiler room contains three Babcock & Wilcox boilears, each having 2531 sq. ft. heating surface and capable of evaporating 8000 lbs. of water per hour. The normal working pressure is 150 lbs. The stack is of steel, self-supporting, and 130 ft. high. It has a 7-ft. internal diameter, and it is lined with 4½-in. fire brick. The stack is erected on piled concrete foundations. The thickness of the steel plates at the base is 7-16 in. Each plate is 4 ft. x 6 ft. and there are three plates to the ring.

The feed water heater employed was supplied by the Wheeler Condenser & Engineering Company. The feed water is heated by the exhaust from the feed pumps, and the condenser pumps. The feed pumps are of the Blake & Knowles type, 6 ins. x 4 ins. x 8 ins. The steam cylinders of these pumps are fitted with an improved outside valve gear, so that they can be adjusted to the full length of the stroke under all conditions of speed. The steam connections of these pumps are so arranged that in case any repairs are required, either pump can be worked independently of the other.



The hot well is situated in boiler house and is fitted with baffle plates, the divisions in which can be filled with coke and straw, if desired, for the purpose of intercepting any oil that may be discharged into it. It is also fitted with suitable outlets, so arranged that, by opening a valve and filling the tank, the oil, which will be found floating on the surface, can be run off. The feed water, before entering the boiler, can be passed through two Edmiston filters, capable of filtering 16,000 lbs. of water per hour. These filters are arranged on a twin system, fitted with the necessary valves to enable the filters to be used on either range of feed pipes.

The steam piping is of steel, with heavy screwed steel flanges, and is so arranged that any engine can be fed direct from the boiler immediately behind it, or, by means of the main, from any boiler. Valves are inserted to enable any faulty section in the piping to be cut out. This piping is also fitted with an automatic atmospheric valve, which, in the event of any back pressure, due to the failure of the condensing plant, will immediately allow the engines to exhaust direct into the atmosphere. The piping on the atmospheric side of this valve is of thin steel, riveted together in spirals.

The engine room contains three McIntosh & Seymour tandem compound condensing engines, running at 135 r.p.m., fitted with expansion governors and separate exhaust valves on both high and low pressure cylinders. The high-pressure cylinder is steam jacketed, and exhausts into a receiver, in the interior of which are fixed three copper coils, which can be heated with live steam. These engines are direct coupled to 6-pole 200-k.w. compound-wound generators, giving 500 volts at 135 r.p.m.

There are two condensers of the Wheeler Admiralty type with engines in the center, air-pump at one end and circulating water-pump at the other end. Each condenser is capable of dealing with 12,000 lbs. of steam per hour. The condensing water is taken direct from the river through from the water works, which can be employed to start the 12-in. cast iron pipes. There is also an auxiliary supply pump in the event of the suction pipe being emptied through the retaining valve not being perfectly watertight.

Adjoining the engine room is the accumulator room. This contains 236 Tudor cells mounted in three tiers. Each cell containing six positive and seven negative plates. The capacity of the battery is 770 amp. hours, the normal rate of discharge 110 amps. and the maximum rate 210 amps. The battery stands are of pitch pine with acid proof paint, and are mounted on large oil insulators. This battery can be charged either from traction or lighting bus bars, as desired, the necessary volts for charging being supplied by a booster, which can also be driven from the traction or lighting bus bars.

POLE

The switchboard is situated at the end of the engine-room, and contains three generator panels, fitted with automatic circuit breakers, with magnetic blow-outs; also the necessary switches, so arranged that the generators can be connected direct to either the lighting or traction bus bars; also two battery panels, fitted with the necessary regulating switches and magnetic blow-outs, and so arranged that the battery can be either charged from, or discharged to, either the lighting or traction circuits, as desired; also two balancer panels, so arranged that, if desired, the balancer can be driven, in the day time, direct from the traction bars, or used as an ordinary balancer, the two motors being in series across the outers, the junction being connected to the neutral. In this case the set is run up to give its correct voltage by means of the motor placed in the center, and the electrical connections are disconnected after the balancer sets are connected to the system.

The switchboard is also fitted with a panel containing the necessary instruments required by the Board of Trade for purposes of testing.

There are eighteen top seat cars, capable of seating forty-four passengers, manufactured by the Brush Electrical Engineering Company, Ltd., mounted on single Peckham trucks, manufactured by the Peckham Truck Company. The motor equipment consists of two G. E.-60 motors with series parallel controllers. The motors had to be specially designed for this work, on account of the very narrow gage, namely, 2 ft. 11½ ins. In other respects the car equipment follows standard practice.

The repair shop is 70 ft. x 18 ft., and contains the necessary machine and smiths' tools likely to be required for the maintenance of the cars and machinery.

The Cork Electric Tramways & Lighting Company,

Ltd., which operates the system, supplies current for lighting and miscellaneous power purposes, as well as for electric tramway service. The lighting distribution is on the three-wire system, with 460 volts between the outers. The mains are all of Messrs. Callender's manufacture, and, in the majority of cases, consisting of jute-covered, lead-sheathed, tape-armored cables, laid direct in the streets. Altogether, over 20 miles of cable, including both lighting and traction systems, have been laid, the distance between the feeding points, of which there are two at present, and the station being just under half a mile.

In their course from the power station to the feeding points, the cables cross the River Lee, and as there is only a swing bridge at this location, the cables had to be laid in a trench excavated in the bed of the river. Callender's vulcanized bitumen wire-armored cable was employed here, as being adapted as most suitable for the purpose. Four additional spare feeder cables, each of .7 in.-sectional area, have been laid across the river to cope with future extensions. The vulcanized bitumen cables are brought together in a pit on each side of the water, where they are connected to the ordinary jute-covered, tape-armored cable laid in the streets.

The greater proportion of the distributing cables in the center of the city are of the three-core type; the largest distributor used has a sectional area of .15 in. In all the outlying districts three single distributing cables are used, and, in addition to their armor, they are further protected by a covering layer of bricks. At the crossing and junction points of the system Callender's disconnecting boxes are fixed, and, of these, nineteen are at present installed.

The supply of current for light, etc., was started about the beginning of September, and since then about 130 customers have been connected to the mains. The service of the company now stands as follows:

Number of customers applied for	217
Lamps applied for	11,622
Motors applied for	18
Total horse power	113
Total applied for in 8 c.p. equivalents	14,447

The public arc lighting has not yet been permanently started. There will be altogether about 100 lamps.

The tariff for lighting current is 5d. per unit for the first two hours, and 1d. afterward, on the Brighton system of charging. The present tariff for motive power is 4¼d. per unit, and 1d. afterward, also on the Brighton system.

CONTRACTORS, ETC.

The British Thomson-Houston Company, Ltd., was the contractor to the Cork Electric Tramways & Lighting Company, Ltd., for the work as a whole—construction, building, machinery, etc.—in connection with the system, and supplied complete electrical equipments of the power station and cars.

The following were the chief sub-contractors to the British Thomson-Houston Company, Ltd.:

Permanent Way, Power House Buildings, Etc.—W. M. Murphy, Dublin.

Engines.—R. W. Blackwell & Co., London.

Boilers.—Babcock & Wilcox, Ltd., London.

Auxiliary Apparatus, Pumps, Condensers, Etc.—Wheeler Condenser & Engineering Company, and Blake & Knowles Steam Pump Works, Ltd., London.

Battery.—Tudor Accumulator Company, Ltd., London.

Traveler.—Jessop & Appleby, Leicester.

Cars.—The Brush Electrical Engineering Company, Ltd., Loughborough.

Peckham Trucks.—R. W. Blackwell & Co., London.

Overhead Line Construction.—R. W. Blackwell & Co., London.

Feeders and Cables.—Callender's Cable & Construction Company, Ltd., London.

Arc Lamps and Hoods.—General Electric Company, Ltd., London.

Alderman Fitzgerald, of Cork, was sub-contractor to W. M. Murphy for the buildings in connection with the power house.

Recent Improvements in San Francisco

The favor with which the many electric lines constructed by the Market Street Railway Company during the past five years have been received by the traveling public, and their ability to cope with the requirements of grades and heavy travel having been fully demonstrated, the company decided to reconstruct other lines to the electric system, which work has been completed during the year just passed.

The Park and Ocean Line, formerly operated by steam motors, from Stanyan and Haight Streets, along H Street (the southern boundary of Golden Gate Park), to the ocean beach, has been converted to the electric system. The double track, about 4 miles in length, has been rebuilt, using 62-lb. T rail, spiked to redwood ties 6 ins. x 8 ins. x 8 ft., space 2½-ft. centers, with fish-plate joints resting upon joint plates. The tracks are cross bonded every 300 ft. Center-pole construction has been used for the electric conductors the greater portion of the way, though for a short distance, at the town end of the line, iron side poles of the Market Street Railway standard pattern have been used. The center poles, which are spaced about 109 ft. apart, are set in concrete, extending about 12 ins. above the surface of the ground. Fig. 8 trolley wire has been used, of 330,000 c.m. cross sectional area. All span, anchor and strain wires are of silicon bronze, on account of the salt atmosphere met with.

The line, which has many grades of about 2½ per cent, one of which is over a mile in length, is operated mainly with single-truck cars of the combination open and closed pattern, which run direct to a central part of the city, though on Sundays a few cars of the double-truck pattern (also combination open and closed) are run between the ocean beach and Stanyan Street only, to accommodate the passengers transferring to and from the lines having their terminals at the latter point. Since the conversion of this line to the electric system the travel on it, which is almost entirely of a pleasure character, has greatly increased.

The Eighth Street line, formerly operated as a horse line, between Market and Bryant Streets, a distance of about 3100 ft, has been rebuilt to an electric road. The double track has been relaid with 45 to 51-lb. girder rail, on chairs spiked to redwood ties 8 ins. x 8 ins. x 8 ft., spaced 2½-ft. centers, with the rail joints cast welded. Ordinary side-pole construction has been used, the poles being of the 5-in., 6-in. and 7-in. tubular iron, Market Street Railway standard pattern. To avoid an extra number of poles upon the street, at various places the iron side poles were omitted, and the suspension wires secured to 40-ft. and 50-ft. wooden poles, already in place, for carrying the wires of other companies.

San Bruno and Precita Avenue and Army Street: The unused horse-car tracks on Army Street, between San Bruno Avenue and Folsom Street, have been rebuilt to the electric system, as also a single electric track constructed on Precita Avenue, between the same streets, with the intention of extending the Folsom Street line out to the former street and San Bruno Avenue, a distance of about 2½ miles, returning to Folsom Street via Army Street. The single tracks constructed on Army Street and Precita Avenue are each about 2500 ft. in length, and built of 51-lb. girder rail, spiked direct to ties spaced 2½-ft. centers, with rail joints cast welded. Ordinary wooden side-pole construction was used on this portion of the route.

The reconstruction of the San Bruno Avenue horse-car track is now under way, the T rails of the present track being relaid on new ties spaced 2½-ft. centers, with rail joints cast welded and rails cross bonded every 150 ft. with No. 0, B. & S. Chicago bonds. Wooden side bracket poles are to be used in the overhead construction. The reconstruction of the line has been treated as of a somewhat temporary character on account of the unfinished condition of the street and the prospect of many future changes in its grade, etc.

Taylor Street: The horse car, double tracks, on Taylor Street, between Market and Ellis Streets, a distance of about 1250 ft. have been reconstructed for electric service, using 70-lb. girder rail, laid on chairs spiked to 6-in. x 8-in. x 8-ft. ties, spaced 2½-ft. centers, with fish-plate joints. The overhead work is of the standard Market Street Railway pattern, with iron tubular side poles. This track, which was constructed for the immediate use of the Park & Ocean through line, may possibly be used in connection with other lines in the near future.

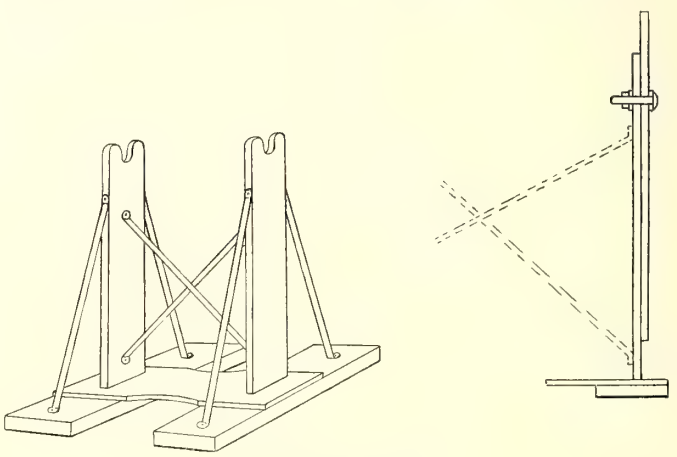
During the year the company has put in several hundred cast-welded joints on its Ocean Avenue, Kearny and Sacramento Street lines, with excellent results. While a few of the joints put in last year on the Solano, Folsom and Twenty-second Street lines had to be renewed on account of breakage, no such trouble has been experienced with those of this year's construction.

Sixteen cable cars, no longer required on account of the conversion of certain cable to electric lines, have been reconstructed to single-truck electric cars of the standard combination open and closed pattern, with very satisfactory results. These cars have been equipped with motors taken from larger cars, as noted below.

The electrical equipment of twenty-five double-truck cars has been improved by substituting two G. E.-1000 motors for the two W. P.-50 motors formerly used, and which were found to be hardly adequate to the requirements of grades, heavy loads and frequent stops. A portion of the W. P.-50 motors so removed have been used in equipping the smaller cars of the single-truck pattern, previously referred to.

The Kentucky Street car house has been enlarged during the year, and its capacity increased from forty to eighty cars, the company now having storage capacity at its three electric car houses for 300 cars.

The pipe line, running from the bay to the main electric power station at Bryant and Division Streets, for supplying salt water for condensing purposes, has been extended to the cable power station at Market and Valencia Streets, and the non-condensing power plant at that house remodeled to one of a condensing type by the addition of a new low-pressure cylinder, condensers, pumps, etc. The electric light system of the company has been extended until, from its own power station, all of its sixteen car houses and power plants are now lighted.



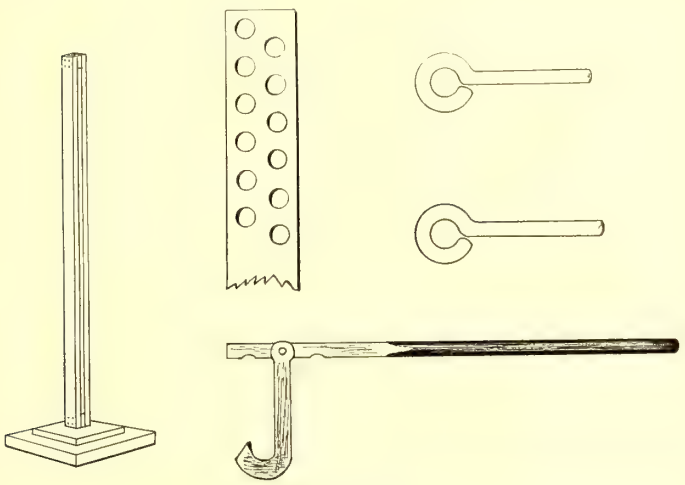
The introduction of electric motors to operate drill presses and grind-stones at the car houses has been attended with economical results. It has been found that a small motor, absorbing 10 cents' worth of current per day, will run a drill press faster and stronger than an able-bodied man can do it. Twice the work is now done with one man and a motor as was formerly done by two men.

Home Made Armature Rest.

The accompanying engravings illustrate a stand for holding armatures while repairs are being made, used at the Fifty-second Street shop of the Brooklyn Heights Railroad Company. The stand, with the exception of a few iron braces, is made entirely of wood, and so should be quite inexpensive to build. The idea seems to be a good one, as the device will apparently withstand extremely hard use for a long time before having to be consigned to the scrap pile.

The method of making the stand is as follows: Two upright pieces on which the armature shaft rests are made from a board, either ash or oak, and 1¼ ins. thick. Each side should be cut about 7 ins. wide and 36 ins. long. One end of each piece is securely fastened to a connecting base board, cut from the same plank but 12 ins. wide and 38 ins. or 40 ins. long. The edge of this latter piece is cut out crescent shape to give a more finished appearance to the completed stand. When this has been done it should be fastened to two pieces of plank, each 3 ins. x 9 ins. x 36 ins., which will support the frame from the floor.

The two upright pieces are braced with ½ in. round bar iron as explained by referring to the illustrations. It will be noticed that two braces hold these pieces from spreading out, and two fastened at the edge of each one near the



ARMATURE REST

top and at the ends of the pieces resting on the floor hold it from falling over. After these have been added the top edge of each upright piece must be hollowed out to fit the shaft, and the stand is complete ready for service. To increase the height or width two additional pieces may be fastened with two bolts to the uprights on each side as explained in the engraving on the right.

At the same shop two traveling cranes, operated by hand power, are employed to raise car bodies from their trucks, but these will be found in most all large shops having modern improvements for doing repair work. But the jack used for handling small car bodies appears to be very useful and a device which would be found very convenient in smaller shops. The following illustrations will explain how to make it. First cut two strips of hard wood 1½ ins. x 8 ins. x 8 ft. long, and have two rows of holes 1½ ins. in diameter bored in each piece. The distance between the holes is about 6 ins. The centers of the holes in one row should come opposite the center of the space between the holes of the other row, and the holes in each strip should correspond with those in the other. The two strips are then bolted together at each end, leaving a space between of about 3 ins., or sufficient to allow the lever, also illustrated, to pass easily in or out. When this has been completed the uprights should be fastened securely to a base, which can be made from a block of wood 4 ins. or 5 ins. thick and 18 ins. square, or made from two pieces nailed together, one about 4 ins. thick and 16 ins. or 18 ins. square, the other 2 ins. thick and 14 ins. square, as shown in the cut.

The lever is made from one piece of bar iron 2 ins. diameter and 6 ft. or 7 ft. long, one end being flattened for a distance of about 2 ft. to a thickness of 1¼ ins. This lever

rests on two iron pins passed through the holes made in the jack, and to keep it from slipping off these pins it is slotted sufficiently deep at these points to hold it in place. Two slots are made on the part of the lever which was made flat, as mentioned above; the first slot is about 1½ ins. or 2 ins. from the end and the other about 6¼ ins. from the first. At the center between these two slots is pivoted the hook for engaging with the car body; this is forged to the form shown. The two pins are made from round bar iron 1¼ ins. in diameter, one end of each being bent in a circular form to facilitate handling, as well as to keep it in place in the jack. It should here be mentioned that the strips of wood of jack having the holes in them can be considerably strengthened by placing bands of iron on the edges; this tends to keep the wood from splitting at these points.

CAR JACK

To raise or lower a car with this jack is simply a matter of changing the position of the pins. Thus to raise the car two jacks are placed at one end with the hooks engaging underneath the platform, one on each corner. The lever is then pressed down on each jack and the pin on each thus released is placed in the next hole above. The lever is again raised and that pin placed in the next hole above. Continuing this operation raises the car body from the truck on one end until a sufficient height is reached where the car body can be held in that position in some convenient way, perhaps by resting it across a timber placed on two barrels outside the track to allow the removal of the truck. The jacks are then taken to the opposite end of the car, which is raised and held in the same manner. Reversing these operations lowers the bar body. It only requires the services of two men to operate this jack.

Special Report to The Glasgow Corporation on Latest Developments in Electric Traction

The following is an abstract of a memorandum by General Manager John Young, on electric traction, in view of practical experience gained in Glasgow and elsewhere during the last two years, and with special reference to the present proposal to equip electrically the lines from Glasgow Cross to Govanhill and Coplawhill Car Works. It was prepared at the request of the convener of the tramways committee:

"Two years ago—in 1896—deputations from the tramways committee reported strongly in favor of electric traction, and to-day it is further ahead of its rivals than ever. At that time the system of distributing the current by means of a slotted conduit in the center of the track was only being experimented with. Mechanically it seemed successful, but considerable doubt existed as to the commercial success of a system so costly to construct. On the other hand, the overhead, or trolley system, had for several years been abundantly proved a commercial success, and to have completely revolutionized tramway traveling wherever it had been adopted. Your deputations, therefore, felt that the only choice left them was to recommend the corporation either to give a demonstration of the overhead system on one of the tramway routes, or simply to wait further developments. The former was the recommendation which was subsequently given effect to, and the overhead construction on the Springburn route, especially in West Nile Street, where rosettes are used, instead of side poles, shows the system practically at its best, and I do not think any slight improvement it may admit of would alter any one's opinion of the system generally.

"It is only within the last fortnight that the horse cars have been entirely displaced by electric cars on the Springburn route, and the power station plant has not yet been completed so as to be taken off the hands of the contractors. Our figures for operating can, therefore, scarcely be said to have settled down to normal. The results, both as regards efficiency and economy, are, however, very satisfactory. For the week ending Saturday last, Nov. 12, the total operating expenses for the electric route were, as near as may be, 6½d. (13 cents) per car mile, while the receipts amounted to 1s. 4½d. (34 cents) per car mile. I do not wish to attach too much importance to the increased traffic, although there can be no doubt electric traction does very appreciably increase the revenue. Apart from this consideration, important as it is, financial success is assured by the fact that, during the first full week of operating our small electric installation working only at half its power, we can show a saving on working expenses, as compared with horse traction, of 2d. (4 cents) per car mile.

"The position we find ourselves in at present is this: We have with difficulty kept pace hitherto with the unprecedented increase in our tramway traffic, and still we find ourselves pressed to give traveling facilities to meet this increasing demand upon us. It would be unfortunate at this time of day to propose to build more stables or horse cars. The only little present relief we can otherwise have, until a general scheme for electric traction has been adopted, is to electrically equip the route in continuation of High Street from Glasgow Cross to Govanhill, and across Coplaw Street to Coplawhill Car Works. An electrical connection between the car works and the power station at Springburn is absolutely necessary, at any rate. It is calculated that the engines and dynamos now in the power station can operate this extension, and, of course, better results will be shown when full advantage is taken of the power plant. Some extra boiler power will be required.

"The desirability of this extension is very apparent, but the question which, in view of the latest developments, has just arisen is: should this extension be on the overhead or underground system, or, rather, should we have a demonstration of the conduit system before finally discussing a complete scheme of electric traction for the city?

"Perhaps one of the most important communications upon electric traction which has yet been made public came into our hands a few days ago. It is the "Comparative costs and profits of cable, electric conduit, and horse tramway operation in New York city." This communication is published in this month's issue of the STREET RAILWAY JOURNAL, New York, and for the information of members I would ask you, with the sanction of the editor, to have it reprinted in the minutes. The figures contained in this article as supplied to the editor by H. H. Vreeland, president of the Metropolitan Street Railway Company, of New York city, seem to confirm the commercial success of the conduit system in that city of great traffic, and its great superiority to cable and horse traction.

"The report states that, for the year ending June 30, 1898, the operating expenses of the cable lines were 8.21d. per car mile; of the horse lines, 8.93d., and of the electric conduit lines, 5.11d.; while for the three months ending Sept. 30, 1898, which is more favorable to the electric conduit system, on account of its operation being more settled, the cable lines cost 8.77d.; the horse lines, 8.94d., and the electric lines, 5.03d. For comparison, I may interject here that last year it cost us in Glasgow 8.3d. to operate with horses. Upon examination of the detailed figures, it is evident that some little addition will soon fall to be made to the cost of operating the conduit on account of increased maintenance of permanent way and equipment when these have been longer subjected to tear and wear.

"Another very remarkable statement in the report is that 'during the twelve-months' period the cable lines operated at 47.7 per cent of their passenger receipts, the electric lines at 37.9 per cent, the horse lines at 65.3 per cent, and the entire system at 53.3 per cent. During the three-months' period the cable operated at 52.7 per cent of their passenger receipts, the electric lines at 38.6 per cent, the horse lines at 62.1 per cent, and the entire system at 50.9 per cent.' This very low percentage of 37.9 of the receipts has never before been reached, so far as I know. It, of course, points to very large traffic, as well as to economical working.

On our system last year the percentage of cost of operation to receipts was 74.49.

"I confess my surprise that the cable in New York, with its immense traffic, should have been so very far surpassed. With these figures before him, and also the significant fact that the cable system in Broadway, after a short history of five years, is now being superseded by the electric conduit, the writer of the article seems fully justified in saying—'There is no place for the cable in modern street railroading.'

"But it is the overhead and the conduit systems of electric traction that you are more immediately interested in.

"Your deputation, in their report of July, 1896, said: 'All other things being equal, a system which provides the power without any overhead construction is preferable.' No one will dispute this. I do not think it is possible, however, with the very much greater initial cost of the conduit, that the result can be economically equal to the overhead, but it may very properly be asked, in view of the latest experience: How near does it approach economic equality? This I have tried to estimate.

"The total length of the tramways owned by the Glasgow Corporation, including those recently constructed, although not yet opened for traffic, measures, in round figures, 37 miles of double track. This, of course, excludes the Govan Tramways, which are leased. Prior to 1894 the section of rail used weighed 79 lbs. per yard, and from 1894 to 1896, 89 lbs. per yard. Since 1896 a new section has been adopted, weighing 100 lbs. per yard. In both of the older sections (designed for horse traction) the groove is so shallow that, when new, the rail admits of a wear of only one-quarter of an inch until the flanges of our electric car wheels touch the bottom of the groove. The new 100-lb. section gives a wear of three-quarters of an inch before the same thing occurs. Our experience in relaying and operating the Springburn route has practically dispelled any hopes that may have been entertained of the economy of bonding and wearing out any considerable portion of the old shallow-grooved rails.

"Of the 37 miles of double line in question, 22 miles are laid with 79-lb. rails, and 6 miles with 89-lb. rails, making altogether 28 miles; and 9 miles with 100-lb. rails. From what I have said, we may take it that, in the event of conversion to electric traction, the former 28 miles will practically require new rails throughout, while the present rails on the latter 9 miles will be suitable for the new form of traction.

"On this basis, I have made up the following relative estimates of the cost of conversion. These estimates do not include anything for feeders, rolling stock, equipments, buldings, power and transforming stations, etc., which are common to both the overhead and conduit systems, and which, for our present purpose, may be estimated at equal cost:

I. OVERHEAD

Renewing 28 miles of double track, and electrically equipping same, including overhead construction, bonding, and ducts for feeders, at £11,000 per mile	£308,000
Converting 9 miles of double track now laid with 100-lb. rails, at £4,500 per mile	40,500
	£348,500

"These figures for the overhead system are based upon the costs of converting the Springburn route.

II. CONDUIT

Renewing 28 miles double track, and electrically equipping same at £20,000 per mile	£560,000
Converting 9 miles of double track, using the present rails, at £18,000 per mile	162,000
	£722,000

"These figures for the conduit bear the same relative proportion to the overhead as do the figures in the very able report recently presented to the Liverpool Corporation by F. S. Pearson, engineer to the Metropolitan Street Railway Company, who designed and constructed the conduit system in New York now reported upon. Mr. Pearson's figures for conversion in Liverpool are, however, somewhat higher than those given here, both for overhead and conduit.

"There is, of necessity, considerable uncertainty in any estimate for constructing a conduit in the streets of the city, arising from the unknown number and character of water, gas, and other pipes and sewers, which may require to be removed, and special work at bridges, etc. In fact, the real cost will be determined by the amount of this extra work.

"According to the present estimates it would cost £373,500 (in round figures, £10,000 per mile of double track) more to convert the 37 miles of double track under consideration to the conduit than to the overhead system, or rather more than double. The greatest sacrifice for the conduit is, it will be observed, in lifting to the foundation the lines more recently laid with 100-lb. rails.

"To construct the conduit on a road on which there are no tramways at present would probably cost about £6,000 per mile of double track more than the overhead. This would apply to extensions.

"Taking an average running of 9,000,000 car miles per annum, or 122,000 per mile of single track, the interest and sinking fund on the extra cost indicated for conversion is practically equal to ½d. per car mile. There will probably be slight excesses on other points, such as maintenance, leakage, cleaning, etc., but, from all the evidence available, I think we may assume that the excess on all points would not, in any event, exceed 1d. per car mile. It should be observed, however, that, on the mileage in question, 1d. per car mile amounts to £37,500 per annum.

"Where the traffic is not great, this excess would be serious, or even prohibitive, and it would tend to check extensions quite feasible with the trolley.

"The interference with the streets would undoubtedly be very great during the reconstruction for conduit, but this would just require to be borne at its possible minimum. Where the street would require to be taken up for the overhead system, it would only be a question of degree. There is also the question of climate. Glasgow has more damp and slush than New York, but I have assumed that the maximum excess of 1d. per car mile over the trolley would cover all such points.

"If we, for the moment, suppose the more expensive conduit system to be quite practicable from an engineering point of view, then its commercial success would depend upon the prospective traffic and receipts. We are naturally most anxious to give the community the cheapest possible means of comfortable tramway traveling, and there is no doubt that, for cheapness and efficiency combined, the overhead electric system holds the field. It is, however, a question worthy of fair and full consideration, whether, if the conduit should prove equally efficient and reliable, and be considered safer, as well as less obtrusive (even if the preference be, to a large extent, sentimental), and if it could be operated at no greater extra cost over the trolley than 1d. per car mile, it should not have a trial at this stage. In other words: is the gain, which is almost entirely æsthetic, worth the difference? Were this the only question involved, I believe the available traffic on the thoroughfares of Glasgow would justify this extra cost over the trolley if by it one were sure of securing for the city the best all-round system. But we have not this assurance.

"The extra cost can be better afforded now that the electric power can be produced at what a few years ago would have been looked upon as merely a nominal addition to the cost per car mile run. It is fully anticipated that the new 70,000-h.p. station in Ninety-sixth Street, New York, for the tramway service of the entire city, through high-tension primary lines and low-tension secondary circuits, will reduce the cost of power to somewhere between 60 cents (30d.) and 75 cents (37d.), or practically one-third of a penny per car mile run. I believe this is possible of realization. Experience in Brooklyn, Chicago and Montreal, as well as in New York, justifies the expectation. I am also convinced that, with the wages and prices in this country, if the Glasgow Tramways committee lay down their own power station on similar lines, they will be in a better position to attain this result than the Metropolitan Street Railway Company, in New York. I may mention here that, from tests made so far, our cars on the Springburn route, which is hilly, and requires considerable sanding, seem to use about 1¼-kw. hours, or board of trade units, per car mile run, or about 1½ units, including currents used for lighting and heating the cars.

"Coming now to the question of the proposed extension from Glasgow Cross to Govanhill and Coplawhill, there is nothing, if it be not insufficient depth on the bridges, to prevent a portion of this extension being altered to the conduit system, and the working of the same cars over both systems, if the committee wish it. The cars would be fitted with the trolley for the overhead portion, and the plow for the conduit portion. The one would be thrown off, and the other on, at the junction—which would be a stopping place—without much detention. The changing may not be altogether desirable, but it is quite workable. One system, however, for the entire city would certainly be preferable. Otherwise there would be difficulty in determining where one system should end and another begin.

"If the available depth makes it practicable, and a demonstration of the conduit system is wanted, what I should suggest is this: proceed at once to equip the Govanhill route, as proposed, on the overhead system throughout, and arrange, at any time you think fit, to demonstrate the conduit system on the Dennistoun route from St. Vincent Place to the terminus. The current for this demonstration could easily be supplied from the present power station, via High Street, and the working costs kept quite separate. The Kelvinside cars could simply turn at St. Vincent Place, as in former times, and this would completely isolate the Dennistoun route for this purpose.

"The article referred to is reprinted from the Street Railway Journal, and is appended hereto. John Young."

LEGAL NOTES AND COMMENTS*

EDITED BY J. ASPINWALL HODGE, JR., AND ROBERT ERNEST, OF THE NEW YORK BAR.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

NEW YORK.—1. Construction of Connections—Necessity of Consent.

The construction of a connecting curve between two street railway tracks, being a necessary incident to the construction of the tracks themselves, is not within Const. art 3, sec. 18 (amendment of 1875), providing that the construction or operation of a street railroad shall not be authorized except upon the condition that the consents of one-half in value of the property bounded on, and the consent also of the local authorities having control of, that portion of a street or highway upon which it is proposed to construct or operate such railroad, be first obtained.

2. Same—Traffic Contracts.

Const. art. 3, sec. 18 (amendment of 1875), providing that the construction or operation of a street railroad shall not be authorized except upon the condition that the consents of one-half in value of the property bounded on, and the consent also of the local authorities having control of, that portion of a street or highway upon which it is proposed to construct or operate such railroad, be first obtained, does not extend to traffic contracts under railroad law, sec. 78, permitting railroad companies to contract with other companies to operate cars over the former's tracks.—(Kunz vs. Brooklyn Heights R. Co., 54 N. Y. Suppl., 187.)

MASSACHUSETTS.—Construction—Assessment of Damages.

Pub. St. c. 109, sec. 4, as amended by St. 1884, c. 306, allowing an assessment by selectmen for damages to abutting property caused by the construction of lines of "companies for the transmission of intelligence by electricity," and "electric light and electric power lines," does not authorize the selectmen to assess damages for the construction of an electric street railroad.—(McDermott vs. Warren B. & S. St. Ry. Co., 51 N. E. Rep., 972.)

VERMONT.—Municipal Corporations—Control of Streets—Construction of Statutes—Effect of Repeal—Proceedings Before Commissioners.

1. V. S. 1894, c. 170, provides (sec. 3936) that, before a street railway corporation shall begin the construction of such railway in a street in any city, such corporation must first obtain the permission of the aldermen of the city, and (sec. 3937) that, if such corporation fails to agree with the aldermen as to the location, manner of construction, or use of such railway, either party may apply to the railroad commissioners, who, after due notice to the parties, shall examine the premises, hear the parties, and decide the questions presented to them, and whose decision shall be final. By acts 1896, No. 148, sec. 53, subd. 44, it is provided that the city council of Burlington shall have power to impose and enforce the terms on which any street railway or traction company may use or occupy any street in such city, and to prohibit such use thereof until such terms have been complied with; and that, if the company and such city cannot agree on such terms, the company may petition the County Court, which shall thereupon hear the parties, fix such terms as shall be reasonable, and make all necessary orders for carrying its decision into effect. Held, that such later enactment by implication repeals the chapter referred to as to the city of Burlington, in so far as such chapter relates to the subject matter of the powers thus conferred on the city council.

2. An application to the railroad commissioners by a street railway corporation for permission to construct and operate such railway in a certain city was not "pending" at the time of the repeal of the statute under which such proceeding was brought, within the meaning of V. S. secs. 28, 29, saving from the effect of such repeal suits and proceedings in civil causes then pending, where such statute was repealed before notice of such application had been served.

3. The words "suit" and "civil cause," as used in V. S. secs. 28 and 29, relating to the effect of the repeal of a statute on actions then pending, do not include proceedings before a board of railroad commissioners, whose functions are merely administrative or ministerial, and whose decision is final.—(City of Burlington vs. Burlington Traction Co., 41 Atl. Rep., 514.)

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

LIABILITY FOR NEGLIGENCE.

INDIANA.—Street Railroads—Negligence Pleading.

1. A street railway company is not liable for failure to stop a car running at a proper speed, on approaching a frightened horse, where it does not appear that thereby the horse could have been controlled, or that the motorman had reason to apprehend the occurrence of an accident.

2. Averments that a street car was run carelessly and negligently, and run at a high rate of speed, making great noise, do not state facts showing negligence.—(Terre Haute Electric Ry. Co. vs. Yant, 51 N. E. Rep., 732.)

NEW YORK.—1. Carriers—Collisions—Questions for Jury.

In an action against a street railway company and the owner of a wagon for negligence, there was evidence that plaintiff sat on the east side of a south-bound car, near the rear. A short distance south of a street intersection, the car met the wagon, coming north on the east track in front of a north-bound car. To get out of the way of the car behind it, the wagon crossed to the west, and collided with the rear of the south-bound car, striking and injuring plaintiff. The gripman of the south-bound car ran it across the intersecting street at full speed, and the wagon driver first started to cross the west track when the car was about 75 ft. away. The wagon was a heavy one, and could not be stopped at once. Held, the issue of negligence was for the jury.

2. Same—Rule of Care Required.

The rule requiring a carrier of passengers to exercise all the care that human skill and foresight may suggest to secure their safety applies to street cars propelled by a cable.—(Keegan vs. Third Ave. R. Co. *et al.*, 54 N. Y. Suppl., 391.)

NEW YORK.—1. Damages—Fright.

Injuries from fright accompanying a physical injury furnish basis for recovery of damages.

2. Credibility of Witness—Interest.

The testimony of employees whose duty it was to inspect electric wires, one of which broke, that they were properly inspected, is that of interested persons; so that their credibility is for the jury.

3. Negligence—Electric Wires.

Plaintiff having been shocked by electricity coming from the ground after it escaped thereto from one of defendant's electric wires after it fell, the jury were justified in holding that the automatic device used by defendant was not properly adjusted, or was not in proper working order; there being evidence that, if it was, it would throw the current off the wire the moment it came in contact with the ground.

4. Opinion Evidence.

The inquiry being, not whether plaintiff's existing conditions might have been produced by the injury, but would her present condition be permanent, a witness, after detailing all the conditions he found present, may give his opinion, without giving a history of the case.—(O'Flaherty vs. Nassau Elec. R. Co., 54 N. Y. Suppl., 96.)

NEW YORK.—Excessive Damages—Personal Injuries.

Three thousand, five hundred dollars' damages for the fracture of the acromion process and of the humerus of a seven-year-old child, where the child suffered, and was likely to continue to suffer, from his injuries, are not excessive.—(Hutchinson vs. Atlantic Ave. R. Co., 53 N. Y. Suppl., 1076.)

NEW YORK.—1. Negligence of Passengers—Standing on Running Board.

A passenger who boards an open street car, where the seats are filled, but where there is standing room in the space between the seats, though uncomfortable and inconvenient, is not guilty of negligence per se in standing on the running board.

2. Same—Sudden Jerks—Negligence of Company.

The seats in an open car were filled, and passengers were standing in the space between the seats. Plaintiff boarded the car, and remained on the running board, where other passengers were standing. The conductor collected his fare without any remarks. It was customary for passengers to stand on such board when the cars were crowded. While going at from 6 to 8 miles an hour, the car gave a sudden violent jerk, occasioned by the sudden application of excessive motor power, which caused plaintiff to break his hold with one hand, swinging his body outward so as to strike a trolley pole. Held, to show negligence making the company liable.—(Hassen vs. Nassau Elec. R. Co., 53 N. Y. Suppl., 1069.)

NEW YORK.—Negligence—Personal Injuries—Damages—Excessive Recovery.

In an action for damages for personal injuries received through negligence on the part of defendant, a verdict for $10,000 was excessive, where plaintiff was not entitled to recover for loss of earnings or for medical attendance, but only damages for the pain and suffering she had endured, and for that which it was reasonably certain she would endure in the future, and where such in-

juries were not permanent, and there was no satisfactory evidence as to how long plaintiff would continue to suffer therefrom.—(Becker vs. Albany Ry. Co., 54 N. Y. Suppl., 395.)

NEW YORK.—Injury to Passenger's Clothes.

A passenger tore her dress in the door latch of a street car, and sued the company. She and her sister testified the catch was a sort of hook, and sharp as a knife, and was worn smooth and bright at the edge. The company's employees testified that it was a new car; that the catch was the same as used on their other cars; and that there was nothing wrong with it, but it was in good order, and they knew of no better appliance for its purpose; also, that each car of the company carried 500 to 600 passengers per day, and no such accident had ever happened before. Held, that she could not recover.—(Atwood vs. Metropolitan St. Ry. Co., 54 N. Y. Suppl., 138.)

NEW YORK.—1. Courts—Constitutional Law—Municipal Court of New York.

Const. art. 6, sec. 18, provides that the Legislature shall not confer on an inferior local court of its creation any greater jurisdiction than is conferred on county courts by the article; section 14 provides that county courts shall have the power possessed at the adoption of the constitution, and original jurisdiction for recovery of money, etc., where defendant resides in the county; Code Civ. Proc., sec. 341, provides that a domestic corporation actually located within a county is deemed a resident of the county; Greater New York Charter, secs. 1358, 1364, divide the boroughs composing the city into districts, and specify the district in which municipal courts shall be held; section 1370, subd. 2, provides that, if defendant be a corporation, action must be brought in a district in which plaintiff resides, or in which defendant transacts business, or has an office or agency; and subdivision 4 provides that, if action is not brought in the proper district, it may be tried where brought, unless transferred on motion of defendant. Held, the jurisdiction of a municipal court over a defendant corporation being expressly limited to a corporation resident in a borough, which, under the charter (section 2), consists of the whole or part of the county, that the provisions of the charter are not in excess of legislative authority, as extending the dominion of the municipal court over more than one county.—(Irwin vs. Metropolitan St. Ry. Co., 54 N. Y. Suppl., 195.)

NEW YORK.—Defects in Tracks—Injury to Traveler.

An injury to plaintiff was caused by a loose street railway rail. The track had been inspected that morning, and ten minutes before the accident a car had passed safely over the rail, and the imperfection was not observable; and, shortly after it, it was discovered and repaired. Traffic on the street was heavy at that hour. There was no showing that the road was improperly laid, or built of poor material, nor that the defect was caused by the company's acts, nor that its method of track inspection was not proper, nor of any previous defect causing the company to apprehend danger from loose rails or spikes. Held, that the company was not shown to be negligent.—(Kelly vs. Metropolitan St. Ry. Co., 54 N. Y. Suppl., 173.)

INDIANA.—Special Verdict—Evidence.

The jury may not return the primary facts on evenly balanced evidence, where the burden of establishing the ultimate fact rests on the party in whose favor the primary facts are returned.—(Citizens' St. R. Co. vs. Reed, 51 N. E. Rep., 477.)

ILLINOIS.—Collision—Damages—Trial—Directing Verdict—Questions for Jury—Appeal and Error—Waiver of Error.

1. Where, at the close of plaintiff's evidence, defendant moves to take the case from the jury and direct a verdict for defendant, and the motion is renewed at the close of all the evidence, a written instruction directing the verdict must be presented with the motion.

2. A failure of defendant to present an instruction directing a verdict with his motion to direct is not supplied by his presenting such instruction with his series of general instructions.

3. Where defendant did not present a written instruction directing a verdict with his motion to direct, the error in refusing to direct was waived by his presenting such instruction with his series of general instructions.

4. It was not error to instruct that if plaintiff's intestate was injured by collision with a street car while exercising due care, and defendant omitted to do certain things, plaintiff could recover, as plaintiff was entitled to have the jury instructed on his theory of the case.

5. In determining the damages resulting from personal injuries to plaintiff's intestate, the jury should consider the nature of the injuries, his physical and mental suffering, and his loss of time.

6. Plaintiff's intestate, two years after receiving personal injuries, died of abscesses which formed on the liver, the cause of which was unknown. In an action for the injuries, held, that the question of the cause of his death was properly withheld from the jury.—(West Chicago St. R. Co. vs. Foster, 51 N. E. Rep., 690.)

MINNESOTA.—Injury to Pedestrian—Contributory Negligence.

Held, that the evidence conclusively shows that plaintiff, in attempting to cross two parallel street railway tracks (at a point not a street crossing), immediately behind a moving car on the track next to him, was guilty of negligence in not exercising reasonable care to ascertain whether a car was approaching from the opposite direction on the other track.—(Greengard vs. St. Paul City Ry. Co., 75 N.W. Rep., 221.)

MINNESOTA.—Contributory Negligence—Personal Injuries—Actions—Evidence—Questions of Fact—Excessive Damages.

1. A boy eight years and four months old got upon the rear platform of a street car, intending to ride thereon to his home, several blocks distant. While sitting upon this platform with his feet upon the car step, where there was no gate, the car started, and while it was running fast the boy became dizzy, fell off, and was injured. The motorman (who was also conductor) knew that the boy was on the car. Held, that merely getting upon the car and sitting down on the platform with his feet on the step was not prima facie evidence that the boy was a trespasser, and whether he was a passenger or trespasser it was not error for the trial court to submit to the jury the question whether it was negligence on the part of the acting conductor to permit him to ride, sitting in that position, while the car was running fast.

2. It was within the province of the acting conductor to compel this boy to go inside the car, or stop it, and put him off; and, if he did not do so, the jury had a right to say that the conductor was guilty of negligence, which was imputable to the company.

3. Held, also, that the rear platform of a street car running fast was a place of danger for this boy, riding thereon, and just what degree of intelligence and prudence could be expected of him was properly left to the jury to determine, as well as whether, upon all of the facts, he was thereby guilty of contributory negligence.

4. Held, further, that the damages awarded were not excessive.—(Jackson vs. St. Paul City Ry. Co., 76 N.W. Rep., 956.)

MINNESOTA.—Master's Liability to Employee.

The plaintiff was engaged in replacing defective wooden poles with iron poles, and placed a ladder, which he climbed, against one of the wooden poles, when the pole, by reason of its rotten condition, broke off at the ground, and he was injured. Held, that the rule that a servant cannot recover damages for an injury caused by the defect which he was employed to repair applied, and plaintiff could not recover.—(Broderick vs. St. Paul City Ry. Co., 77 N.W. Rep., 28.)

MASSACHUSETTS.—Crossings — Collision — Sufficiency of Evidence.

Evidence that defendant's car was going slowly; that plaintiff was nearly across defendant's track at the time of the collision; that plaintiff's view of the track in the direction of the approaching car was obstructed until he was within 15 ft. of the track; that plaintiff looked, but saw nothing, and heard no gong; that he had been going "a little faster than a walk," but "slowed up" before reaching the track, and that upon reaching the track he hurried his horse, is sufficient to warrant submitting to the jury the question of plaintiff's due care.—(Lahti vs. Fitchburg & L. St. Ry. Co., 51 N. E. Rep., 524.)

NEW YORK.—Injury to Child—Contributory Negligence.

A child between eight and nine years of age, who attempts to cross a city street in the middle of a block, either without looking for an approaching street car, or in blind and heedless disregard of its rapid approach, is guilty of contributory negligence.—(Weiss vs. Metropolitan St. Ry. Co., 53 N. Y. Suppl., 449.)

NEW YORK.—Injury to Passenger—Negligence—Question for Jury.

In an action to recover damages for personal injuries suffered by plaintiff in consequence of the defendant's alleged negligence, it appeared that while the plaintiff was riding as a passenger in an open trolley car of the defendant, in the evening a flashing or flaming shot out of the motor box or controller, from 2 to 6 ft. high, enveloping the motorman, and continuing while the car proceeded for some 100 ft. The plaintiff was so much alarmed that she leaped from the car, and received the injuries complained of. There was evidence on behalf of the defendant that the apparatus was a standard appliance, but the flaming on this occasion was of a very unusual character; and it appeared that dirt in the controller was likely to cause such results, that the car in question had not been inspected that day, and that after the accident the controller was found to be dirty. Held, that the facts required the submission to the jury of the question of defendant's negligence.—2. Same—Contributory Negligence.

Held, further, that the fact that other passengers remained in the car could not operate to conclusively establish contributory negligence on plaintiff's part in jumping.—(Poulsen vs. Nassau Electric R. Co., 51 N. Y. Suppl., 933.)

The Paris Exposition of 1900

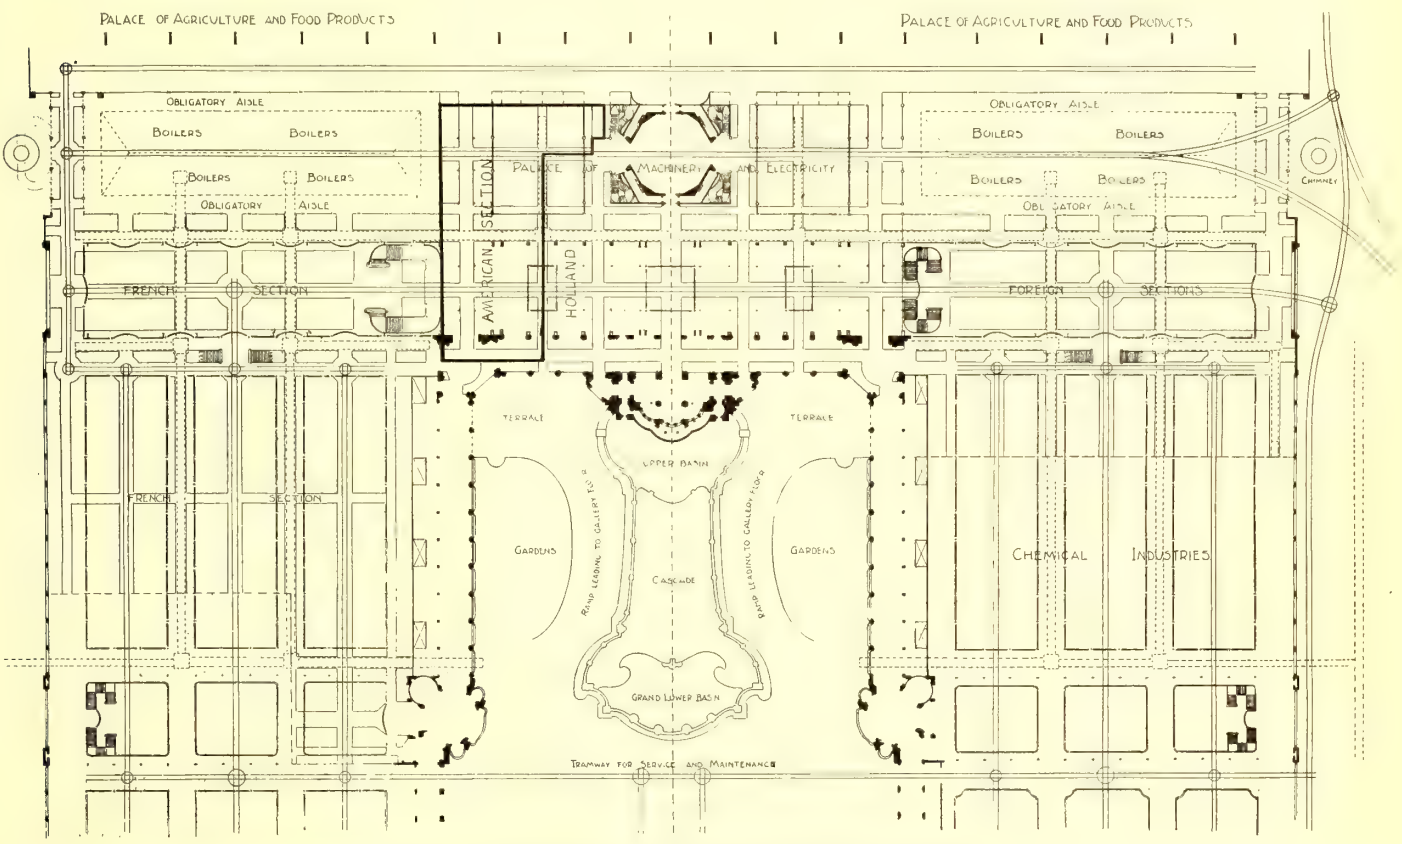
BY FRANCIS E DRAKE,
Director of Machinery and Electricity, United States Commission.

Though occupying only about one-half the area of the World's Columbian Exposition at Chicago, the Paris Exposition of 1900 will have great opportunity for the satisfactory presentation of the arts of peace. The location of the grounds is practically in the heart of Paris on both sides of the river Seine, and affords an unrivaled opportunity for providing comfortably for great crowds.

The great main gate of the exposition will be at the historic Place de la Concorde, and will be capable of admitting 65,000 people an hour. Scores of other entrances will be provided, so that each section of the city may be amply accommodated.

On the south side of the river Seine the majority of the principal palaces and attractions will be installed. The Esplanade des Invalides, a rectangular tract lying immediately north of the Hotel des Invalides, will contain palaces devoted to the exhibition of general manufactures. This tract will be connected with the grounds on the north side of the river and the Champs Elysees by the magnificent new bridge of Alexander III., now under construction. From the Esplanades des Invalides to the Champs de Mars, along the left bank of the river, will be a row of official pavilions of the great nations, among which will be the building of the United States. Between the bridge of the Invalides and the Champs de Mars will be grouped the buildings devoted to the exhibits of the army and navy, and between the Champs de Mars and the river will be a building devoted to marine navigation and another containing the exhibits pertaining to forestry and fisheries.

On the famed Champ de Mars will be found the several great palaces of the Exposition, in which will be housed practically three-fourths of the exhibits. They will be built around three sides of the rectangle and will be named as follows: Palace of Agriculture, Palace of Electricity, Palace of Machinery, Palace of Transportation and Civil Engineering, Palace of Textiles and Textile Fabrics, Palace of Mines and Metallurgy, Palace of Chemical Industries and Palace of Education and Liberal Arts.



The great Eiffel tower, which was such a conspicuous attraction at the Paris Exposition of 1889, will remain at the north end of the Champs de Mars, and no doubt will excite the same general interest among the visitors to this great fair.

On the north or right side of the river will be found, beginning at the Place de la Concorde, in the order named, the two permanent art palaces, a section of Old Paris, Palace of Horticulture and Arboriculture, the Hall of Social Economy and International Congresses, and the Palace of the Trocadero and Trocadero gardens, where the exhibits of the colonies will be located.

At the park of Vincennes, 8 miles distant, will be located an annex to the exposition proper, where the railway exhibits will be placed, also the automobile, bicycle and similar displays. At this annex provision will be made for international athletic sports, and, owing to the attractive character of the park, thousands of people are expected to visit this annex daily. Ample means of transportation from the exposition grounds will be provided both by rail and boat.

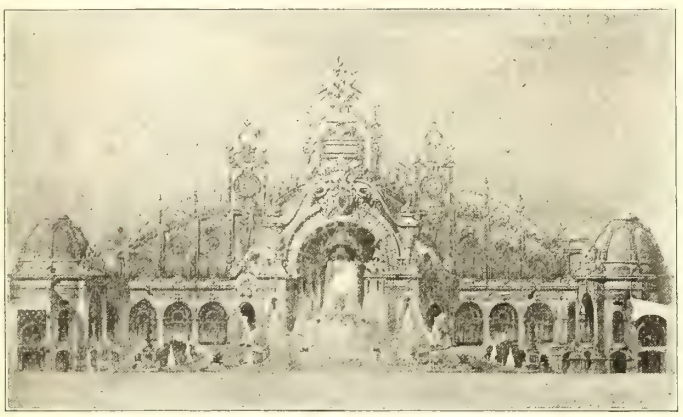
MACHINERY AND ELECTRICITY

The part which machinery and electricity will play in the coming exposition is a more important one than ever assumed by these two great industries in former expositions. In a general way it may be said that but few important changes or improvements will be shown in the service of the Paris Exposition over the Columbian Exposition of 1893. The French classification, however, is a distinct advance over that of any previous exposition, inasmuch as it provides for the installation of the finished product together with the machinery and processes used in connection therewith. Under this classification collective exhibits will be most successful

PLAN OF ELECTRICAL BUILDING—PARIS EXPOSITION

in presenting to the visitors a clear understanding of the state of the art in that particular industry.

GENERAL SERVICE PLANT



The great service power plant of the exposition will occupy a favorable position in the main group of buildings. It will be installed immediately adjoining the space allotted for the exhibits of electrical and other machinery, and any benefit which might naturally accrue to the builder of machinery installed in the service plant will be accentuated by reason of its being located in close proximity to the exhibits not offered for regular service. The capacity of the boiler plants for the service of the exposition will be approximately 20,000 h.p. The two plants will feed into one general system of mains and distributors, and either, or both, may be utilized at the same time, as occasion requires.

The engines and generators for this power plant will be placed in close proximity to the underground subways carrying the steam and other mains. Each power unit must be of the direct-connected type, the generator armature being mounted directly upon the extended shaft of the engine. The designation of these units, according to the exposition nomenclature, will be "electrogene groups." It is proposed by the administration to divide the total power comprised in the several electrogene groups required

equally among the French and foreign builders. From present indications, manufacturers will offer electrogene groups largely in excess of the requirements of the exposition. No actual contracts have as yet been made for them for either the French or foreign sections, except a nominal arrangement entered into some time ago with three German manufacturers, who desire to furnish equipment approximating 5000 h.p.

TRANSPORTATION DIVISION

The exhibit of automobiles or horseless carriages, trolley cars, railway trains, etc., will be made in the special pavilions provided at the annex in the park at Vincennes. A special track will be provided there for trials and tests, and for the daily speeding of auto-

FACADE OF ELECTRICAL BUILDING

mobiles, bicycles, tricycles, etc. The electric vehicle is at present very popular in Paris, and will no doubt come in for its full share of interest.

HISTORICAL EXHIBITS

In addition to the contemporary exposition, the official classification provides for the installation of a retrospective exhibit, which shall present an historical view of the progress in all branches of industry during this century. The department of electricity has been specially favored in this regard by the construction of a special salon d'honneur within the Palace of Electricity, where the retrospective exhibit covering the great field of electricity may be properly undertaken, and where the personal exhibits of the great inventors of the century and the collective exhibits of associations or individuals may, in their several ways, illustrate the evolution and advance of science.

ORGANIZATION AND CLASSIFICATION

For the information of those interested in the organization of the technical service under the director-general of exploitation it is desirable to state that the mechanical installations will be under the immediate direction of Monsieur Ch. Bourdon, professor of the Central School of Arts and Manufactures. The work of this department falls under two distinct categories. The first relates to the execution of the necessary installations for motive power, and may be subdivided as follows:

be subdivided as follows:

(a) Production of steam.
First—Installation of boilers.
Second—Construction of flues and chimneys.
(b) Distribution of water and steam.
First—Construction of Subways.
Second—Installation of steam mains, etc.
(c) Production of power.
Installation of electrogene groups.

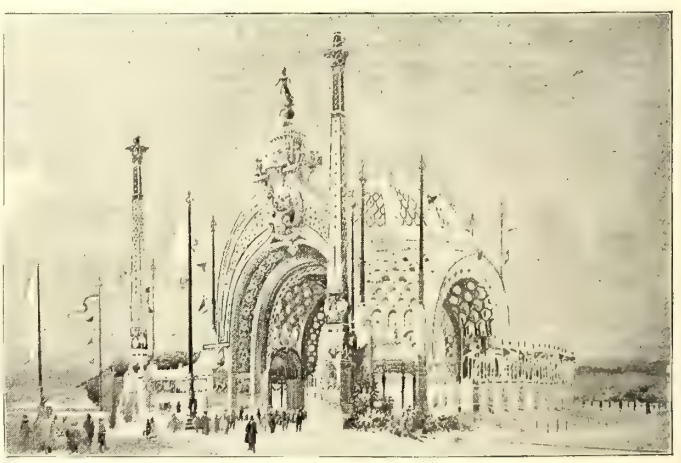
The distribution of motive power is practically assigned to the service of electric installations.

The work under the second category is of an administrative order, and especially concerns the general conditions of exploitation of the boilers and electrogene groups and such other apparatus as is required for furnishing the steam for power service.

The total mechanical power furnished will be in the neighborhood of 20,000 h.p., of which 15,000 h.p. will be for electric lighting and 5000 h.p. for motor service. These figures, while not absolutely correct, are those used by the administration as the basis of the installation.

In the two power plants the boilers will be placed in two lines of batteries, with the boilers back to back. Ample space for general circulation of the public has been provided.

The location of the electrogene groups operating as generating units for the power plant will be within the regular exhibit space devoted to the department of machinery and electricity. Electricity will furnish the motive power for the operation of an intramural elevated railway, which will encircle the Champs de Mars, pass in front of the main palace on the Esplanade des Invalides, and along the Quay d'Orsay from the bridge of Alexander III. to the Eiffel tower.



There will be no regular compressed-air service established by the exposition administration, but arrangements will be made with the City Public Service Company whereby compressed air mains will be brought into the exposition buildings and air service offered to the exhibitors at the regular city rates, less 10 per cent.

SERVICE POWER PLANT

The controlling minds of this great undertaking have not lost sight of the artistic side of questions surrounding the service power plant, and in the construction of the chimneys for the two boiler plants ample provision has been made for the æsthetic treatment of the exterior of the towering stacks which will conduct the gases from the furnaces.

Two monumental chimneys have been designed, each to be handsomely ornamented. The height of each will be 230 ft. above the level of the Champs de Mars, the inside diameter at the base 28 ft., and at the summit 23 ft. These chimneys are to be illuminated at night, and will thus trace a striking outline upon the dark background of the sky.

In appropriating funds for the power plant the administration has, upon the advice of the technical committee, provided a minimum sum, which may be said to be only about one-third of the allowance made for the use of power units at the Columbian Exposition of 1893. The great commercial rivalry between the principal nations of Europe has been a factor in determining the course of the administration. Many large concerns would have granted the use of engines and dynamos during the period of the exposition without charge, providing advantageous arrangement of space, etc., could have been assured them. It was after mature de-

PRINCIPAL GATE TO PARIS EXPOSITION

liberation, however, that the authorities settled upon a very normal compensation, which should apply alike to French and foreign manufacturers.

The details and conditions surrounding the tenders of electrogene groups are recited in the official specifications appended:

GENERAL CONDITIONS OF INSTALLATION AND EXPLOITATION OF ENGINE DYNAMO GROUPS

Art. I. General Requirements.—The electrical energy required for the Paris Exposition of 1900 will be produced by engine-dynamo groups, the steam engine of which will operate condensing; the generator armature to be mounted direct on the engine shaft, thus excluding all cables and belts.

The administration will contract either with one builder only for the combined group, or simply with the builder of the steam engine and with the builder of the generator.

Art. II. Technical Requirements.—The steam in the main pipes will have a mean effective pressure of 142 lbs. per square inch; this pressure may vary 10 per cent either above or below normal.

The electric current generated will be delivered to a switchboard furnished by the contractor. The following voltages will be permitted:

Continuous current.....125, 250 or 500 volts.
Alternating current.....2,200 volts with a frequency of 50.
Three-phase current.....2,200 volts with a frequency of 50.

Art. III. Special Requirements.—As the apparatus installed under these articles will also be considered as exhibits, the conditions of the general regulations of the exposition will apply to these groups.

The apparatus will be submitted to the examination of the international jury and admitted to compete for awards. In consequence of this particular stipulation the furnishing of these apparatus will be made under the same conditions as govern other exhibited apparatus, that is, nothing will be granted to the exhibitor as allowance for expenses except for the installation and exploitation of the apparatus, which remuneration is specified in Art. IX., below.

Art. IV. Conditions of Installation.—The installation of the apparatus will be made according to plans established by the builder and accepted by the director general of exploitation on a favorable report of the technical committee and annexed to each copy of the contract. The builders will conform to the regulations enjoined by the administration concerning public safety.

Foundations.—The administration will furnish the necessary floor space to the exhibitors, who will provide all foundations and accessory works at their own expense.

The materials employed for the construction of the foundations will remain, after the exposition is over, the property of the builders, who may remove or abandon them as they may elect.

Piping.—The steam engine builder will establish at his expense special piping to his engine from the main steam pipe provided by the administration. A throttle valve will be supplied by the engine builder at the junction of his piping with the exposition mains. The engine builder will also furnish and erect the feed-water pipes and evacuation pipes for the hot water of condensation, as well as all necessary valves, traps, etc., to be placed at the junction with the main piping. The pipes conveying live steam and cold water as well as for the outlet of the hot water from condensation will be placed in underground conduits connecting the engines to the underground galleries in which are installed the main distributing pipes. These main galleries and pipes will be established by the administration, and the private piping will be installed by the exhibitors at their expense. Special regulations will fix the details to be observed concerning valves and joints.

Switchboards.—Each generator will be provided with a switchboard having the necessary means of interruption and protection such as are usually employed, also current-measuring apparatus to be approved by the administration. The administration also reserves the right to require the use of current-registering apparatus.

For the alternating-current generators the contractors will be obliged to furnish and install the necessary transformers for the distributing stations, so that the current of these alternators may be rendered available.

ART. V. DURATION OF SERVICE.—The duration of service is that of the exposition itself, that is, from April 15 to Nov. 15, 1900, 205 days. The administration reserves the right to vary this period not exceeding thirty days, in which case no modification concerning the remuneration allowed will be made.

ART. VI. DAILY SERVICE.—The duration of each day's service and the duration of working hours will be determined by the director-general of the exposition according to service requirements. The builders agree to furnish at any time the maximum amount of power they have undertaken to supply.

The director-general of the exposition will establish between the several builders an equalization of work so as to permit proper working and resting periods for facilitating the visiting, cleaning and repairing of apparatus without causing any inconvenience to, or disruption of, the regular service.

ART. VII. MEASUREMENT OF ENERGY.—The administration, with the assistance of the contractor's employees and at his expense, will make such experiments and tests as are necessary to ascertain if the engines and generators are capable of furnishing the power stipulated in the private contracts. An official report will be made concerning these tests. At any time during the exposition period these tests may be renewed to verify the previous reports.

ART. VIII. FINANCIAL CONDITIONS.—The live steam required by the engines and water for condensing will be furnished by the administration free of charge. The builders will receive: (1) A fixed sum to remunerate them for a portion of the prime installation expense; (2) a sum proportionate to the number of hours of work at the normal rating of the group as accepted by the administration. These sums will be fixed according to the power of the units as determined in the private contracts and in accordance with the following tables (the amount to be contributed by the administration toward the first cost of installation is presented in Tables No. 1 and No. 2):

TABLE NO. 1.

Total allowance:	Engine.	Dynamo.	Together.
Total maximum contribution	$46,330	$19,300	$65,630
Amount allotted to the French section (Plant La Bourdonnais)	23,165	9,650	32,815
Amount Allotted to foreign section (Plant Suffern)	23,165	9,650	32,815

TABLE NO. 2.

Allowance per indicated horse power:	Amount allowed per horse power. Engine.	Dynamo.	Together.
For the first 1000 h.p.	$1.92	$ .78	$2.70
For 1000 to 1500 h.p.	1.37	.24	1.61
For all above 1500 h.p.	1.00	.18	1.18

In the event of the maximum horse power accepted by the administration from foreign builders being such as to make the total remuneration based on Table No. 2 greater than the total sum for this service as established in Table No. 1, a proportionate reduction will be made on the horse power allowance for each builder which shall be commensurate with the increase in total horse power over the limit established by the appropriation.

The capacity of the groups admitted for service will be so proportioned that this reduction will not exceed 50 per cent.

TABLE NO. 3.

((Sums representing the administration's contribution toward the expense of exploiting and operating the electric groups).

Allowance per i.h.p. per hour.	Per Horse Power. Engine.	Dynamo.	Together.
For the first 1000 h.p.	Cents 0.162	0.138	0.300
From 1000 to 1500 h.p.	Cents 0.067	0.057	0.124
Above 1500 h.p.	Cents 0.056	0.046	0.102

The administration guarantees to the builders a minimum duration of work fixed at 500 hours.

ART. IX. TERMS OF PAYMENT.—The remuneration above stipulated will be paid to contractors as follows: On July 10, 1900, payment of the number of working hours furnished from the beginning of the exposition up to and including June 15; on Sept. 10 for the number of working hours furnished from June 15 to Aug. 15; one month after the close of the exposition the balance covering the number of working hours furnished after Aug. 15. That portion of the remuneration allowed toward first cost of installation will be paid in thirds on the same dates.

ART. X. DATE OF DELIVERY.—The contractors agree to begin the foundations for the engines and dynamos not later than October 15, 1890. If at that time they have not taken possession of the space granted to them and are unable to show satisfactory progress in the construction of the apparatus and in arrangements for prompt delivery, thus assuring the administration of the fulfilment of their obligations, the right to cancel without indemnity the contract between the administration and the contractor is reserved to the exposition officials.

The contractors must complete the installation of their groups on or before March 15, 1900; on this date will begin the trials mentioned in Art. VII.

ART. XI. PENALTIES EXACTED FOR DELAYS.—In event of delay beyond the time fixed in Art. X. for the installation of the units, the administration will exact the following penalties and will deduct them from any sums which may ultimately be due to contractors from the exposition. (1) A penalty equal to the allowance corresponding, for the apparatus referred to, to the normal service of the group during a working day of seven hours; (2) a penalty on the allowance made for installation expenses, which will be calculated by multiplying the amount of this remuneration by a coefficient of reduction equal to the ratio of the number of days delayed to the total duration of the exposition.

ART. XII. CANCELLATION OF CONTRACT FOR EXCESSIVE DELAYS.—If the apparatus is not in condition to furnish a regular service beginning with May 15, 1900, the administration reserves to itself the right to cancel the contract made by the builder without indemnity being due to either party, and without remuneration for installation expenses to be paid by the administration.

ART. XIII. PENALTY IN EVENT OF INTERRUPTION OF SERVICE.—In case of interruption to the regular service, aside from the resting hours fixed by the director-general of exploitation, the contractor will have imposed by the administration for each day of said interruption a penalty equal to the allowance corresponding, for the apparatus referred to, to the normal service of a day of seven working hours.

If this interruption exceeds a period of ten days, a second penalty will be exacted and deducted from the remuneration provided by the administration toward the installation expenses, which penalty will be calculated by multiplying the amount of such remuneration by a coefficient equal to the ratio of number of days of delay to the total duration of exposition.

ART. XIV. EMPLOYEES.—The director-general of the exposition will retain the right to require the discharge of any agents or employees in the service of contractors for insubordination, incapacity, intemperance or want of probity.

ART. XV. MEDICAL SERVICE.—The builders, being considered as exhibitors, as stipulated in Art. III., will not be classed as contractors for the masonry work required; therefore, the amount of their contracts will not be submitted to the customary deduction of 1 per cent for medical service required in Art. XVI. of general conditions.

On the other hand the employees of the builders, in case of injury or accident, will receive only the "first help to the injured," the regulations of Art. III. and IV. of the "Arrêé Ministériel" not applying to them.

ART. XVI. GENERAL REGULATIONS.—The contractors agree to conform to all the regulations promulgated by the director-general of the exposition. They will be held responsible for accidents caused by their apparatus or employees.

Disagreements between the administration and contractors must be, previous to any definite action, examined by three competent members of the technical committee. One of these members will be chosen by the commissioner-general of the exposition, the second by the contractor, and the third will be chosen by the two first-named members.

The contractors agree to withhold any procedure or action at law until after having submitted the disagreement to the council of arbitration as above provided for.

In the main the general conditions of installation and exploitation of steam boilers are similar to those governing the engine-dynamo plant, but there are some special features which are presented in the following abstract:

SPECIAL CONDITIONS OF BOILER INSTALLATION

ART. I. GENERAL REQUIREMENTS.—The steam required for the production of motive power for the Universal Exposition of 1900 will be produced by two distinct plants; one, called "Usine La Bourdonnais," being reserved for French builders, will be placed in the court of 117 by 40 meters situated between the Palace of Electricity, Palace of Agriculture, Palace of Machinery and the passage along the Avenue de la Bourdonnais; the second, reserved for foreign builders, will be placed in a court situated next to the Avenue Suffren and called "Usine Suffren."

These boiler plants will be formed by groups of boilers, each group being able to produce under normal conditions a minimum of 22,000 pounds and a maximum of 44,000 pounds of steam per hour.

The administration of the exposition will not contract for more than one group with the same builder.

ART. II. SPECIAL REQUIREMENTS.—Same as Art. III., engine-dynamo groups.)

ART. III. CONDITIONS OF INSTALLATIONS.—(Same as Art. IV., engine-dynamo groups, with the following additions:)

Chimney Flues.—The main flues for smoke from both boiler plants will be established at the expense of the administration. Junction pieces will be prepared to receive the ends of the flues from the different groups of boilers. The private flues connecting the boilers to the main flues will be made by the contractors at their expense after the approval of the plans by the director-general of exploitation.

Smoke Stacks.—A large smoke stack will be established by the administration for each boiler house.

Steam Pipes.—The administration will furnish the main piping connecting the boiler houses with the engine rooms and the different parts of the exposition where steam is required, but each builder must furnish at his expense the connection from his boilers to said main pipes.

Feed Water.—The administration will furnish main feed-water pipes through which will be conducted the water required for the boilers, but contractors must connect their feed tanks or pumps to these mains.

Sewerage. General Sewer pipes will be established by the administration. The contractors will be required to make at their expense the connections to the sewers from the boilers, blow-offs, drains, etc.

Condensers.—To avoid the escape into the atmosphere of the steam used in the different auxiliary apparatus, the administration will erect independent condensers into which this steam will be evacuated.

Main overflow pipes for these condensers will also be established by the administration, but the contractors must connect their apparatus thereto at their own expense. They must also establish a security escape into the open air.

ART. IV.—TECHNICAL CONDITIONS.—The steam apparatus must comply with the conditions of French laws and the regulations concerning public security unless exceptions have been granted by the Minister of Public Works, that is, apparatus built according to legal requirements and subjected to official security tests established by law in the originating country may be accepted upon the proper recognition of such requirements and tests being in consonance with French law. The administration, on the advice of the technical committee, reserves the right to require such other safeguards or safety appliances as it may deem necessary for apparatus working near the public aisles and passageways.

The boilers and their accessories must be established and the conditions of regulation carefully observed for a normal working pressure of 156 lbs. per square inch.

Plans of Installation.—General and detailed drawings must also be submitted to the technical committee, this committee prescribing the conditions to which the builders must conform in the installation they undertake.

The committee may particularly require satisfactory arrangement concerning the installation of the boilers from the chimney flues, water pipes, steam pipes, etc. All feed pipes, etc., must be installed and maintained in perfect condition.

The furnaces shall be constructed so as to avoid the production of opaque smoke, the fuel adopted by the builder being carefully selected with this end in view.

ART. V. MEASURING AND CONTROLLING APPARATUS.—The builders agree to mount on their boilers such indicators, gages or verification apparatus as the director-general of exploitation may deem necessary, and to have such experiments made as the technical committee or jury of awards may demand.

The builders will furnish, mount and keep in repair at their own expense during all the time of the exposition a suitable water meter of one of the patterns accepted by the administration, to be installed on the pipe supplying the feed water to their boilers, readings of the meter to be taken every day by the inspector of mechanical service, who shall keep the key to such water gage; two seals will be placed by said inspector on the feed and outlet pipes of the meter.

The builders agree not to blow off the boilers except in the presence of said inspector, and will make sure that the evacuation and overflow cocks are closed in due time, so as not to show erroneous results concerning the evaporization.

A special steam outlet will be located between the boiler and the main throttle valve, according to the conditions to be prescribed by the director-general of exploitation, which shall permit the measurements of the water carried away by steam.

Arrangements will also be made for the reading of the temperature of the gases escaping from the furnaces and for analyzing them.

ART. VI. DURATION OF SERVICE.—(Same as Art. V., engine-dynamo groups.)

ART. VII. DATE OF DELIVERY.—(Same as Art. X., engine-dynamo groups.)

ART. VIII. DAILY SERVICE.—(Same as Art. VI., engine-dynamo groups.)

ART. IX. FINANCIAL CONDITIONS.—The feed water will be furnished free of charge, according to the conditions of Art. III. As explained in that article, the chimney flues as well as the general steam feed, sewerage and overflow

pipes will be furnished by the contractors at their expense, as well as dampers, cocks, gutters, and in a general way, all other accessories required.

The administration will furnish the boiler house. The fuel, necessary employees and all other expenses concerning the installation as well as for the exploitation and trials will be at the expense of the builders. The exploitation will therefore entirely be at the expense of the builders, particularly that which concerns fuel, employees, etc., and these expenses will be settled directly by them without any interference by or responsibility resting on the administration, which will in no case assume any expenses incurred inside of the grounds of the exposition by the builders engaged to furnish the steam.

Within the grounds no fuel, ashes, etc., shall be allowed to be stored, except in sacks.

The remuneration allowed to builders includes: (1) A fixed sum representing the administration's contribution toward the expense of installation of boilers and their accessories. This sum is fixed at $289.50 per 2200 pounds of productive capacity of steam per hour, as contracted for by the administration and appearing on the private contract of each builder. This productive capacity will be determined by the technical committee and will, in any case, not exceed 122 pounds per square ft. of grate surface.

(2) A sum representing the administration's contribution to the expense of exploitation, which sum is fixed at 85 cents per 2200 pounds of steam effectively produced from the opening to the close of the exposition and during the working hours fixed by the director-general of exploitation.

Art. X. Terms of Payment.—(Same as Art. IX., engine-dynamo groups.)

Art. XI. Penalties Exacted for Delays.—(Same as Art. XI., engine-dynamo groups.)

Art. XII. Cancellation of Contracts for Excessive Delays.—(Same as Art. XII., engine-dynamo groups.)

Art. XIII. Penalty in Event of Interruption to Service.—(Same as Art. XIII., engine-dynamo groups.)

Art. XIV. Accounts.—The administration reserves the right to take for the regulation of the accounts any steps necessary, or to make tests and trials so as to be informed as exactly as possible concerning the power produced by the boilers and accessories.

Art. XV. Regulations.—(Covered in Art. XVI., engine-dynamo groups.)

Art. XVI. Employees.—(Same as Art. XIV., engine-dynamo groups.)

Art. XVII. Responsibility.—(Covered in Art. XVI., engine-dynamo groups.)

Art. XVIII. Medical Service.—Same as Art. XV., engine-dynamo groups.)

Art. XIX. Disagreement.—(Covered in Art. XVI., engine-dynamo groups.)

INCLINED ELECTRIC ELEVATORS

A new feature of the exposition service is the "escalader," an inclined elevating way, constructed in the form of an endless carpet or belt, propelled by a drum at one end. No former exposition has made such generous provisions for means of carrying the public to the galleries, and as the typical "escalader" has been so recently brought into public use, nearly everyone in the commercial world will be anxious to see the results obtained with it. The extent to which the elevating stairway may be successfully used can scarcely be estimated at this time. They are said to be safe, easily installed, simple to operate, and their capacity is far in excess of vertical elevators so far as transportation from floor to floor of large crowds is concerned. Such devices have long been sought for large stores, elevated railway stations, etc. Privilege has been granted the commissioner-general for the United States to install a working exhibit of one or more of these "inclines" in or near some United States section.

The terms under which the inclined electric elevators are to be installed are essentially the same as those of other exhibits that find a place in the service plant of the exposition. There are special conditions, of course, and details of construction that may prove interesting to those considering this class of apparatus. The competition will be divided into two lots, one comprising thirteen elevators in the palaces fronting on Avenue Suffern, and the other fourteen in the palaces fronting on the Avenue de la Bourdonnais and Constantine.

The following abstracts from the official specifications cover the principal points of interest:

The inclined elevators, their electric motors, means of transmission and other accessories, will be established in conformity with the general regulations to the general design accompanying these articles.

The beams supporting the inclined elevators will be supported on the upper floor by one or two pillars resting on a solid mass of masonry level with the ground floor. They may also be supported at some point of their lines by one or two additional pillars, in line with the pillars of the palace proper.

The bay to be cut through the upper floor will be established by the administration at its expense. The contractors shall provide for a platform of a particular type acceptable to the aministration. The bay will be 6 ft. 6¾ in. in width and 32 ft. 9¾ in. long.

The apparatus will be constructed for one file of passengers, and the proportions will be as follows:

Width of carpet or elevating surface.....23⅝ in.
Distance between railings.....35 7-16 in.
Grade of incline per foot (approximately)..... 4 in.
Capacity of the elevators in passengers.....20 passengers
(Normally one person per yard.)
Capacity of elevator in passengers.....40 passengers
(At maximum of two persons per yard.)
Distance between the surface of ground floor and the surface of the gallery floor.....23 ft.

The apparatus will be installed for a minimum speed per second of 19 11-16 in. and a maximum speed per second of 23⅝ in.

The conveyor, properly speaking, will consist of an endless belt or platform constructed of pliable and yet resisting material, which will roll continuously and uniformly, and must possess both softness and necessary rigidity for the service to be performed.

When in operation the rolling surface must so move over the supports or rollers as to cause no perceptible or disagreeable effect beneath the feet of the passengers.

The devices for stretching this moving surface, or scheme for "taking up the slack," must allow for all the elongation which may be produced during the entire period of the exposition, so that it will not be necessary to dismantle any portion of the elevator during such time.

The entire inclined elevator must work absolutely without noise. All mechanical apparatus connected with the elevator which may need oiling or greasing must be so arranged as to avoid all possibility of contact with passengers or their garments.

The electric motor and the apparatus for driving the elevator must be placed as near as possible to the elevators.

All parts must be accessible, either from the ground floor or the platform on the gallery floor, for the maintenance in operation.

Proper arrangements must be made so that, in event of damage or accidents to the motor or mechanism, the rolling surface loaded with passengers cannot receive a descending movement.

The side rails will be also formed by endless cables, so constructed that they will present under the hands of the passengers a soft and clean support.

The upper part of this endless cable or moving side rail at the height of the hand will only be seen; the lower part will be inclosed by framework which will have a perfectly plain and smooth surface offering no possibility of accident to the garments of the passengers. These moving side rails must have precisely the same speed as the elevating surface proper.

The tests of capacity of the elevators will be made under a load of 7780 lbs., representing the weight of fifty passengers, uniformly spread over the lines of the elevator. This load will be retained as long as deemed necessary by the administration.

As it is impracticable to make the tests of capacity under a load equal to fifty passengers, which should be renewed in a continuous fashion, the device for stretching the endless belt or moving elevator will be arranged in such a manner as to give to it a tension corresponding to that which it would receive under the weight of fifty passengers or the equivalent of 7780 pounds.

Under this tension the maximum speed must be maintained continuously as may be required by the administration.

The electric current necessary for the electric motors will be supplied by the exposition without expense to the contractor.

The remuneration of the contractor will consist of a fee to be exacted of each passenger using the elevators; this fee shall be ten centimes per passenger.

A percentage of each fee for the right of the concession will be allowed the exposition, and the amount of such percentage is to be indicated in the proposition of the bidders; the liberality of this percentage will largely influence the choice of the successful contractors selected by the exposition.

The contractor will be authorized to collect from the public direct the fee of ten centimes for each passenger.

ELECTRICAL FEATURES

Among the special features of interest to electrical men will be the illumination of the grand entrance, and the big wheel. The latter is larger than the Ferris wheel at Chicago, and differs in many important details of construction.

Not all of the main palaces will be lighted at night. The Palace of Manufactures, Palace of Electricity, Palace of Transportation and Civil Engineering, Palace of Textiles, and perhaps one or two other palaces, will be well illuminated every evening. The great Hall of Fetes, which occupies a central position in the Palace of Agriculture, will be illuminated brilliantly whenever in use for evening gatherings. The Palace of Education and Liberal Arts, Palace of Mines and Metallurgy, Palace of Chemical Industries, and Palace of Agriculture will not be equipped for evening illumination.

It is the Palace of Electricity, to which all eyes will naturally turn at night, and, as its main facade reaches across the entire width of the open plaza in the center of the Champs de Mars, splendid opportunity will be afforded for the attractive treatment of the architectural features of the exterior of this palace. Immediately in front of the Palace of Electricity is the grand Château d'Eau, which, as planned, will assume the character of an immense fountain with a series of cascades, to be effectively illuminated by vari-colored lights, thus making a most brilliant and striking attraction for the evening. A very ingenious scheme has been undertaken in connection with this Château d'Eau. All of the water used in the power plant for condensing purposes is to be discharged through the Château d'Eau and the cascades surrounding it, thus making use of this water in artistic effects, and obviating the necessity of pumping from the river another great volume of water simply for fountain use.

The administration has considered well the necessity for making the gallery space in the various palaces as accessible to the public as possible, and provision has been made not only for numerous vertical elevators of steam, electric and hydraulic type, but for a large number of inclined elevating ways, or "rolling carpets," to carry the passengers easily and speedily from the crowded ground floor to the galleries, where many interesting and instructive exhibits will be installed. The limited ground area at this exposition makes necessary the husbanding of all available gallery space. On the Champs de Mars there will be installed fourteen of these elevators, or "escaladers," which will have a capacity each of not less than 3000 passengers per hour. A fee not exceeding two cents for each passenger will be charged for the use of these "escaladers."

Decision in the Series Parallel Controller Case

The United States Circuit Court of Appeals (Judge Shipman writing the opinion) on Dec. 17, 1898, decided in favor of the plaintiffs in the case of the Electric Car Company, of America, and the Thomson-Houston Electric Company vs. the Nassau Electric Railroad Company, for alleged infringement of the patent issued to George Herbert Condict. The exclusive right under this patent for trolley roads is owned by the Thomson-Houston Electric Company. The patent covers broadly the modern form of series parallel controllers, in which both series-parallel changes and resistance changes are combined, so that by the movement of the same controller handle, both modes of regulation are utilized, and the resistance changes supplement and assist the series-parallel changes.

The Court, in its opinion, said in part: "It cannot be denied that

Condict's combination of two existing systems for regulating the supply of the current to an electric car motor was previously unknown and that the invention was one of much importance. * * * It is also obvious that the mixed controller system is in use whether the insertion is preparatory to or accompanies the shifting of the motor switch, and that in all the forms used either by the defendant in this case or by the defendant in the Hartford case auxiliary resistance was brought in at the time of making the change to parallel. * * * There is and there must be a substantial use and an enjoyment, more or less partial, of the benefits of the Condict idea and system, although the insertion of the dead resistance takes place during the transitional positions which result in a change from series to multiple." Since the original decision, a petition for a rehearing was presented and denied by the Court.

Railway Men in the Late War

Caryl D. Haskins, late commander of the volunteer electrical corps of the Boston Battalion during the late war, has written the STREET RAILWAY JOURNAL in regard to a statement in the last issue in connection with the part taken by the Boston office of the General Electric Company in the coast defense. Mr. Haskins states that while quite a large portion of the staff of that office did take part in the harbor defense work, they did so not as General Electric men, but as individuals and members or officers of the Volunteer Electrical Corps, Boston Battalion. Fully two-thirds of the squad officers and a large proportion of the privates of the battalion were associated with electric lighting companies, construction companies, or other companies foreign to the General Electric Company, so that it is not the desire of the latter that the mistake of giving it all the credit should be made.

There was another unintentional injustice in the same article, to which Mr. Haskins calls attention. This was in the omission of the name of E. H. Hoyt. Mr. Hoyt, who is well known in street railway circles throughout the state, and is chairman of the street railway committee of the State of Massachusetts, served as a special staff officer in connection with the Boston Battalion of the Volunteer Electrical Corps through almost its entire period of service. He dropped all of his important interests, abandoning his duties as representative of the Massachusetts House, and devoted himself exclusively to harbor defense work in connection with the corps, entirely without recompense and to his own personal loss.

Insulating Paint Abroad

The insulating compounds of the Standard Paint Company, popularly known under the name of P. & B., are so extensively employed in this country that American readers will be interested to know that the company is enjoying a very large export trade. Indeed, so large has this trade become during the last few years that after a number of visits abroad Mr. Shainwald, president of the company, decided some time ago to build a branch factory at Hamburg, Germany. The erection of this factory was begun in July, 1897, and completed in 1898, since which time all the compounds and apparatus manufactured by the Standard Paint Company in this country have been supplied by the branch factory at Hamburg. These include not only the P. & B. paint, tape, varnish and other goods which pertain directly to the electrical trade, but also P. & B. rubberoid roofing, P. & B. building sheathing and insulating papers and P. & B. preservative roof and structural paints.

It is a good indication of the standing of this company's products that material which has proved so popular in this country is regarded as equally indispensable in the countries of Europe.

An Advertising Bureau

With the closing of this year, the Manufacturers' Advertising Bureau, of New York city, complets the second decade of its existence—a fact which demonstrates beyond question the value of a concern of its unique character to the progressive manufacturer. Established in 1879 by the present proprietor, Benj. R. Western, the bureau has grown steadily in public favor and commercial importance. Its clientage is a large one, and comprehends representative concerns in nearly every industry in the country.

The Manufacturers' Advertising Bureau makes a specialty of the trade journals, and Mr. Western is, perhaps, one of the best-informed gentlemen in the advertising business regarding this class of publications and their conditions and possibilities as business bringers. A booklet, having the attractive title, "Advertising for Profit," is issued by the Manufacturers' Advertising Bureau, and will be sent on application.

Prospects for 1899

The results of an investigation recently conducted by the STREET RAILWAY JOURNAL shows that a large number of street railway companies are planning to make extensions and improvements during the coming year. Details of some of the new work proposed are given below:

ARKANSAS

The Hot Springs Street Railway Company will probably extend its line about 2 miles.

ALABAMA

The Birmingham Traction Company will probably add to its power station equipment two 300-kw. direct connected generators.

The Mobile Light & Railroad Company expects to add a direct connected generator and engine to its power station and build new car shed and repair shops.

The People's Street Railway and Improvement Company, of Decatur, is planning to reorganize the company and build 4 miles of new track.

CALIFORNIA

The Oakland Railroad Company will reconstruct about 7 miles of cable and horse lines, equipping them with electricity, and will replace twelve grip cars with motor cars. The care are in process of construction.

The Market Street Railway Company, of San Francisco, has not yet fully decided upon further construction and reconstruction for next year, but is planning to do considerable new work. The company has a franchise for an electric line about 1 mile in length, which may possibly be built. There is also a possibility that all the remaining horse lines and steam lines will be equipped with electricity.

The Sacramento Electric, Gas & Railway Company will not build any new mileage during the year, but may make an extension of existing electric transmission lines for power and lighting.

The following roads report that no new work is in contemplation: Gerry Street, Park & Ocean Railroad Company, San Francisco; San Jose & Santa Clara Railroad Company, Santa Rosa; Central Street Railway Company, Santa Rosa; Santa Rosa Street Railroad Company, Santa Rosa; Union Street Railway Company, Santa Rosa.

CONNECTICUT

The Hartford Street Railway Company will build a ¾-mile extension.

The Norwich Street Railway Company will build a ½-mile extension.

The Norwalk Tramway Company will probably build a line from Norwalk to New Canaan.

The Putnam & Thompson Street Railway Company, in connection with the People's Tramway Company, of Danielson, Conn., will construct, early in 1899, 16 miles of single track, together with power station and building equipment.

The following roads report that no new work is in contemplation: Norwalk Street Railway Company, Norwalk; Middletown Street Railway Company, Middletown; Bristol & Plainville Tramway Company, Bristol.

DISTRICT OF COLUMBIA

The Columbia Railway Company will build 10 miles of new suburban line, equipped with the overhead electric system. It will also change the existing cable road to underground electric, will add two 750-h.p. Allis engines and two 525-kw. G. E. generators to its power station, and will increase its rolling stock by sixty motor cars, twenty of which will have double trucks.

The Capital Traction Company will reconstruct about 1¾ miles of double track to conform with the electric conduit system now used on the city lines.

The Washington, Arlington & Falls Church Railway Company will extend its present line for a distance of 3 miles.

FLORIDA

The Pensacola Electric Terminal Railway Company will probably equip 4 miles of steam dummy line with electricity, and will extend present lines about 2¼ miles.

The Palatka Heights Street Railway Company has no new work in contemplation.

GEORGIA

The Augusta Railway & Electric Company has recently completed a new 1½-mile extension, and has installed a 4-kw. 2-phase generator for electric lighting purposes. During 1899 a 400-kw. railway generator will also be added.

The Atlanta Railway Company expects to build 11 miles of new track and add about twelve more motor cars.

The following roads report that no new work is in contempla-

tion: Columbus Street Railway Company, Columbus; City Electric Railway Company, Rome.

ILLINOIS

The Alton Railway & Illuminating Company will build 5 miles of new line and will add five new 28-ft. motor cars. It will also build a new car house, and will install a hot water heating plant for the heating of its buildings. This company is now engaged in relaying 2½ miles of old track and making a ½-mile extension.

The Chicago City Railway Company is planning to make many additions and extensions early in 1899.

The Galesburg Electric Motor & Power Company will add two double-truck motor cars, new motors and new boilers to its present equipment.

The Streator Railway was sold, Oct. 8, and bought by C. C. Barr, who expects to place the property in first-class condition early in the spring.

The Springfield Consolidated Railway Company has not fully determined on improvements for the next year.

The Belleville Electric Railway Company will rebuild about 3 miles of track.

The Rockford Railway, Light & Power Company will build several extensions to present lines.

The City Electric Railway Company, of LaSalle, will make extensions in the spring and add one more generator to the power station. The present rolling stock will be repainted and thoroughly repaired.

The City Electric Railway Company, of Decatur, will probably extend to Fair Haven Park, a distance of ½ mile, next spring.

The following roads report that no new work is in contemplation: Aurora & Geneva Railway Company, Aurora; Calumet Electric Street Railway Company, Chicago; North Kankakee Electric Light & Railway Company, Kankakee; Kankakee Electric Railway Company, Kankakee.

INDIANA

The Union Traction Company, of Anderson, has recently completed its line from Alexandria west to Arestes, 3 miles, and is extending the same to Elwood, a distance of 7 miles further. The company will erect at Alexandria a power station completely new, with 600-kw. generators, with necessary engines and boilers.

The John S. Crumps Street Railway Company, of Columbus, has not decided on new extensions for the coming season.

The Kokomo Street Railway Company will add 1 mile of new track and four new motor cars.

The South Bend Street Railway Company will build a new line to Notre Dame College, a distance of 1½ miles, and will also make other extensions amounting to about 2 miles. A new power station will be erected.

The following roads report that no new work is in contemplation: North Vernon & Vernon Street Railroad Company, Vernon; Logansport Street Railway Company, Logansport; Terre Haute Electric Railway Company, Terre Haute.

IOWA

The Waterloo & Cedar Falls Rapid Transit Company will build 1½ miles in Cedar Falls, and will add to the power station equipment one 300-h.p. engine and one 250-kw. generator.

The Boone Electric Street Railway & Light Company will build 3½ miles of new track.

The Marshalltown Light, Power & Railway Company intends to equip some of its open trail cars with motors.

The Omaha & Council Bluffs Railway & Bridge Company has recently built a new power station, and has no further work in contemplation.

The Sioux City Elevated Railway Company is lowering its elevated structure and extending it on the surface a distance of eight blocks into the city, giving this company a surface line all through the business district.

KANSAS

The Atchison Railway, Light & Power Company has not fully decided what new work will be undertaken, but will probably make some extensions of track.

The Leavenworth Electric Railroad Company expects to build a new car barn, to be modern in every respect and to accommodate forty cars. New shops will also be added.

The following roads report that no new work is in contemplation: Citizens' Railway Company, Fort Scott; Topeka Railway Company, Topeka.

KENTUCKY

The Ashland & Catlettsburg Street Railway Company will increase the capacity of its power station.

The following roads report that no new work is in contemplation: Paducah Street Railway Company, Paducah; Frankfort & Suburban Railway Company, Frankfort.

LOUISIANA

The New Orleans City & Lake Railroad Company will equip with electricity two miles of horse lines and will add six new double-truck motor cars, and will rebuild twenty others.

MAINE

The Sanford & Cape Porpoise Railway Company will build a new line from Sanford to Cape Porpoise, a distance of 22 miles.

The Bangor, Hampden & Winterport Railway Company will extend its line about 8 or 10 miles.

The following roads report that no new work is in contemplation: Bangor Street Railway Company; Biddeford & Saco Railroad Company, Biddeford; Fryeburg Horse Railroad Company; Mousam River Railroad, Sanford.

MARYLAND

The Baltimore, Middle River & Sparrow's Point Electric Railroad Company intends to double its present steam power plant, add ten more cars, and extend its tracks possibly 6 miles.

The following roads report that no new work is in contemplation: Baltimore & Northern Electric Railway Company, Baltimore; Cumberland Electric Railway Company.

MASSACHUSETTS

The Palmer & Monson Street Railway Company will make several extensions to its lines.

The Braintree & Weymouth Street Railway Company expects to build from 4 to 8 miles of new line.

The Shelburne Falls & Colrain Street Railway Company will extend its line for a short distance.

The Boston Elevated Railway Company will build its new elevated structure during 1899.

The following roads report that no new work is in contemplation: Greenfield & Turner's Falls Street Railway Company, Greenfield; Athol & Orange Street Railway Company, Athol; Fitchburg & Leominster Street Railway Company, Fitchburg, Lowell & Suburban Street Railway Company, Lowell; Newton & Boston Street Railway Company, Newton; Newtonville & Watertown Street Railway Company, Newtonville; Wellesley & Boston Street Railway Company, Newtonville; Northampton Street Railway Company; Springfield Street Railway Company; Worcester & Marlborough, Worcester; Taunton Street Railway Company.

MICHIGAN

The Long Lake, Durand & Corunna Electric Railroad Company has recently been formed to build a line from Fenton and Durand to Corunna.

The Adrian Electric Street Railway Company will build ¾-mile extension.

The Escanaba Electric Street Railway Company will build 3½ miles of new track laid with 60 lb. steel T rails; 200-h.p. engines and generators will be added to the power station, and new carhouse and shops will be built. Two large interurban cars will be added to the rolling stock.

The Michigan Traction Company proposes to connect Kalamazoo and Battle Creek with an electric railway 23 miles long, with a spur 3½ miles from Augusta to Gall Lake. The road has been surveyed and part of the material is on the ground. It is thought operation will be commenced in June, 1899.

The Manistee, Filer City & Eastlake Railway Company will build about 3 miles of new track. This company has recently enlarged its power house and increased its power house equipment. The company is also opening a large park on the shore of Lake Michigan.

The following companies report that no new work is in contemplation: City Electric Railway Company, Port Huron; Muskegon Railway Company; Menominee Electric Light, Railway & Power Company; Detroit, Fort Wayne & Belle Isle Railway, Detroit; Detroit & Pontiac Railway Company, Detroit.

MINNESOTA

The St. Cloud City Street Car Company will extend its line 1½ miles to the Great Northern Passenger Depot.

The following companies report that no new work is in contemplation: Twin City Rapid Transit Company, Minneapolis; Lakeside Railway Company, Duluth.

MISSISSIPPI

The Meridan Street Railway & Power Company is adding new boilers to its station equipment.

The Greenville Street Railway Company has abandoned its old property and the track has been taken up. but it is the purpose of

the company to establish a new road some time in the near future.

The following road reports that no new work is in contemplation: Bluff City Railway Company, Natchez.

MISSOURI

The Hannibal Railway Company proposes to build at least 2 miles of new road to Oakwood, and possibly 10 miles more to Palmyra. The present line will also be extended about 3 miles. A new power house will be built and equipped, and new rolling stock and equipment will be added.

The Brooklyn Avenue Railway, of Kansas City, now operated by cable, will be converted to the overhead electric system and 15 miles of extensions (also electric) will be built during the spring. Work will be commenced as soon as the weather permits. A new bridge will be built over the Belt Railway tracks, a new power house erected, and new rolling stock and equipment will be purchased.

The Northwest Electric Railway Company, of Kansas City, is preparing to rebuild its entire line.

The Clinton Street Railway Company is endeavoring to secure capital to equip the road with electricity.

The following roads report that no new work is in contemplation: Electric Railway, Light & Power Company, Sedalia; St. Louis & East St. Louis Electric Railway Company, St. Louis; People's Railroad Company, St. Louis; Citizens' Street Railway Company, Cape Girardeau.

MONTANA

The following road reports that no new work is in contemplation: Bozeman Street Railway Company, Bozeman.

NEBRASKA

The Nebraska City Street Railway Company expects to change from horse traction to electric traction in the latter part of 1899.

The following roads report that no new work is in contemplation: Benson Railway Company, Benson; Lincoln Traction Company, Lincoln.

NEW JERSEY

The Atlantic City Electric Railway Company expects to make some additions to power station equipment.

The Bridgeton & Millville Traction Company is planning an extension to Cedarville, a distance of 4 miles.

The Union Traction Company, of Rutherford, has the construction of 7 miles of new line under consideration, but it is not decided definitely when the same will be built.

The Bergen County Traction Company, of Undercliff, expects to complete its extension to Hackensack, a distance of about 4 miles.

The Trenton Passenger Railway Company will build 2 miles of new line.

The Ocean City Electric Railroad Company recently completed 5 miles of new line and installed new equipment in its power station. No new work is contempleted for 1899.

The following roads report that no new work is in contemplation: Brigantine Transportation Company; Camden, Gloucester & Woodbury Railway Company, Camden; North Hudson County Railway Company, Hoboken.

NEW HAMPSHIRE

The Laconia Street Railway Company will extend its line about 5 miles along the lake shore.

The Exeter Street Railway Company will build from Exeter to Epping, a distance of 6 miles, and from Hampton to North Hampton, a distance of 3 miles, in the spring, and will add about 400-h.p. engines and generators to the power station.

The following road reports that no new work is in contemplation: Nashua Street Railway.

NEW YORK

The Brooklyn Heights Railroad Company has contracted for 150 thirteen-bench open cars and 5000 tons of 9-in. steel girder rails. This rail, when laid, will complete the change of the entire Brooklyn Heights system from horse traction with various kinds of rails to electric traction with standard 9-in. construction.

The Elmira & Horseheads Railway Company will complete a short extension to a new park which it will open to the public in June, 1899, and will also rebuild 3 miles of the present line with 60-lb. T-rails.

The New Paltz & Wallkill Valley Railroad Company will probably add some small motor cars.

The Metropolitan Street Railway Company, of New York City, is now equipping existing horse lines with the underground electric system, and this work will probably be completed during 1899.

The Kingston City Railroad Company may possibly add six or eight new cars to its equipment.

The Hornellsville Electric Railway Company is planning to erect a new power station, and equip some with gas engines.

The Dunkirk & Fredonia Railway Company is endeavoring to secure franchises for building 1 1-3 miles of new track.

The Auburn Street Railway Company will make an extension of its lines about 9 miles in length.

The Syracuse, Skaneateles & Moravia Railroad Company is a new company recently incorporated, and expects to build several miles of track in the spring.

The Green County Traction Company, of Coxsackie, has recently been incorporated, and intends to build a new line in the spring.

The Buffalo, Hamburg & Aurora Railway Company intends to build a new line 21 miles in length in the early spring.

The Saratoga Traction Company will extend its present line to Ballston Spa.

The following roads report that no new work is in contemplation: Bennington & Hoosick Valley Railway Company, Hoosick Falls; Rochester Railway Company, Rochester; Ossining Electric Railway Company, Sing Sing; Oneida Railway Company, Oneida; Niagara Falls, Whirlpool & Northern Railway, Niagara Falls; The Niagara Falls & Suspension Bridge Railway Company, Niagara Falls; Herkimer, Mohawk, Ilion & Frankfort Electric Railway Company, Mohawk; Middletown-Goshen Traction Company, Middletown; Fonda, Johnstown & Gloversville Railroad Company, Gloversville; Citizens' Street Railway Company, Fishkill-on-Hudson; Cortland & Homer Traction Company, Cortland; Buffalo & Niagara Falls Electric Railway Company, North Tonawanda.

NORTH CAROLINA

The Intermontaine Railroad Company, of Asheville, will put in a new plant to be operated by water power.

The following roads report that no new work is in contemplation: Wilmington Street Railway Company, Wilmington; Winston-Salem Railway & Electric Company, Winston; Charlotte Electric Light & Power Company, Charlotte.

OHIO

The Ashtabula Rapid Transit Company has recently completed a number of improvements, including a number of new turnouts, a signal block system and additional shops and car barns. The car barn is heated by steam.

The Oakland Street Railway Company, of Dayton, will make a number of improvements in its property.

The Lima Railway Company will build a ½-mile extension.

The Citizens' Electric Railway, Light & Power Company, Mansfield, is remodeling its power station equipment.

The Tuscarawas Electric Company, of New Philadelphia, is considering the advisability of building a line from Uhrichsville to Cadiz.

The Springfield Railway Company will rebuild 1 or 2 miles of present track and will extend its line about 1½ miles. It also intends to build a new car barn with capacity for thirty-five cars and to add six new cars to the present rolling stock.

The Tiffin, Fostoria & Eastern Electric Railway Company is engaged in finishing its line. All power station equipment has been ordered, but the company may wish to purchase a few more cars.

The Toledo Traction Company will probably lay some additional double track and add one or two railway generators. It may possibly also purchase a few more open cars.

The Cleveland & Eastern Railroad Company is constructing a new line, but new cars, motors or electrical equipment have not yet been ordered.

The Akron, Bedford & Cleveland Railroad Company will double track a considerable portion of its line.

The Worthington, Clintonville & Columbus Street Railway Company is considering the advisability of operating trail cars on its lines.

The Pennsylvania & Ohio Railway Company, of Ashtabula, is a new company which intends to build 45 miles of electric railway. It is also intended later on to continue the line to Erie, Pa., a distance of 26 miles. Part of this road has already been constructed, and as soon as the spring opens the work will be pushed through as rapidly as possible.

The Cleveland, Medina Southern Electric Railway Company will build a new line from Cleveland to Wooster.

The following roads report that no new work is in contemplation: Sandusky, Milan & Norwalk Electric Railway Company, Sandusky; Salem Electric Railway Company, Salem; Tuscarawas Railroad Company, New Philadelphia; Lorain Street Railway Company, Lorain; the Price Hill Inclined Plane Railroad Company, Cincinnati; Cincinnati, Newport & Covington Railway Company, Cincinnati; Chillicothe Electric Railroad Company, Chillicothe.

OREGON

The City & West Portland Park & Motor Company, of Portland, intends to extend the present line 12 miles and equip its existing steam line with electricity.

PENNSYLVANIA

The Beaver & Vanpool Electric Street Railway Company will make a short extension of its line.

The Schuylkill Valley Traction Company, of Norristown, will probably make a number of improvements and extensions.

RHODE ISLAND

The Newport Street Railway Company is asking permission from the city to build a small extension.

SOUTH CAROLINA

The following road reports that no new work is in contemplation: Charleston Street Railway Company, Charleston.

TENNESSEE

The Electric Street Railway Company, of Clarksville, has completed surveys for a new line to New Providence, 2½ miles in length.

The Memphis Street Railway Company expects to build about 2 miles of new track and to construct a car barn and office building, with paint, carpenter and machine shops, etc. The buildings will be 320 ft. x 300 ft. and 105 ft. x 150 ft.

The Nashville Street Railway Company will probably buy some new motor cars and rails for 4 or 5 miles of track.

TEXAS

The Dallas Rapid Transit & Terminal Railway Company is now in process of reorganization. The road will be completed in January, 1899, and several changes and considerable improvement are contemplated.

The Dallas & Oakcliff Electric Railway Company contemplates making some changes, but has not fully decided upon them as yet.

The Austin Rapid Transit Railway Company contemplates a short extension of its line. This company is replacing the old pine ties with mountain cedar ties.

The Uniontown Electric Railway Company expects to make an extension of two miles in the spring.

The Titusville Electric Traction Company will add one new 325-kw. G. E. generator and one new Atlas Corliss engine and boiler.

The Connellsville, New Haven & Leisenring Street Railway Company will build 3 miles additional track from Leisenring to Vanderbilt, and also renew 4 miles of old roadbed with new track. track.

The Pennsylvania Traction Company, of Lancaster, is planning to build about 17 miles of extensions.

The Quakertown Traction Company is planning to build a line from Quakertown to Perkasie and Doylestown, a distance of about twenty miles.

The following roads report that no new work is in contemplation: Paris Railway Company, Paris; Citizens Railway Company, Waco; San Antonio & Magoffin Street Railway Company, San Antonio; El Paso & Juarez Avenue Street Railway Company, El Paso.

UTAH

The following roads report that no new work is in contemplation: Ogden Electric Railway Company, Ogden; Salt Lake Rapid Transit Company, Salt Lake City; Salt Lake City Railroad Company, Salt Lake City.

VERMONT

The following road reports that no new work is in contemplation: Rutland Street Railway Company, Rutland.

VIRGINIA

The Portsmouth Street Railway Company has under consideration an extension of its line.

The Lynchburg & Richmond Street Railway Company will construct an extension 1½ miles long; 90-lb. girder rail in paved streets, and 55-lb. T rail in unpaved streets will be used. This company intends to greatly improve and beautify its park covering about thirty acres, and will put in attractions of various kinds.

The Staunton Street Car Company may extend its line about one mile in the spring. This company is now remodeling its open cars, making combination cars of them, with removable vestibules.

The following road reports that no new work is in contemplation: Richmond Traction Company, Richmond.

WASHINGTON

The West Street & North End Electric Railway Company, of Seattle, expects to extend its line to Army Post, a distance of two miles.

The Seattle & Rainier Beach Railway Company is remodeling its rolling stock and roadbed.

WEST VIRGINIA

The Charleston Street Railway Company expects to build a 1½-mile extension to Ruffner, purchase a rock crusher and rock-ballast all its track outside of paved streets; also to relay about 1½ miles of old 50-lb. T rail, and lay new 62-lb. T rail on new ties.

The following road reports that no new work is in contemplation: Consolidated Light & Power Company, Huntington.

WISCONSIN

The Fox River Electric Railway Company, of Green Bay, expects to extend its De Pere line about two miles into the city of De Pere, and cross the river to the West Side. This company has ordered one new double-truck car, and will probably order two more during the year.

The following roads report that no new work is in contemplation: Sheboygan Light, Power & Railway Company, Sheboygan; La Crosse Street Railway Company, La Crosse; Ashland Light, Power & Street Railway Company, Ashland.

CANADA

The Montreal Island Belt Railway Company will make extensive extensions during 1899.

The St. Thomas Street Railroad Company will make a ½-mile extension and purchase new cars.

The Halifax Electric Tramway Company will build three miles of new track, and add a 300-kw. rotary transformer to the power-station equipment.

The Belleville Traction Company has six miles of extension under consideration.

The Quebec, Montmorency & Charlevoir Railway proposes to build a double track-line from Quebec to Montmorency Falls, a distance of 6.27 miles, and change a 30-mile steam road to electric traction.

The British Columbia Electric Railway Company, of Vancouver, will make several extensions during the coming year.

The following roads report that no new work is in contemplation: Niagara Falls Park River Railway Company, Niagara Falls; Oshawa Railway Company, Ontario; London Street Railway Company, London.

New Law Requiring the Licensing of Private Detectives

A law of considerable interest to street railway companies hiring private detectives or "spotters" has recently been passed by the New York Legislature, through the efforts of A. L. Drummond, general manager of Drummond's Detective Agency, of New York city. This statute requires all private detectives and private detective agencies to take out a license before they can do detective work of any kind. A penalty of a fine of $500, or imprisonment for a year, or both fine and imprisonment, will be imposed upon all offenders of this regulation. The principal reason for the law was the number of unexperienced and irresponsible people who were going into the detective business. Under the new statute, the license fee is $20 a year, and every applicant must have five reputable freeholders of his county to sign his application, and in addition to this he must give a bond of $2,000.

The strong points urged for the new regulation are as follows: At a small cost a man becomes a licensed detective, and he must be a very poor sort of a man and detective who cannot get five reliable indorsers as to his qualifications. It is thought that the requirement of a bond will also be a very valuable feature, as it gives clients something to fall back upon should a detective commit any fraud. This bond, of course, can be sued upon.

The law covers all special policemen, special peace-officers, special watchmen, and other private detectives of any character.

NEWS OF THE MONTH

The Boston Elevated Railway Company has decided to adopt the service stripe system for all uniformed employees. One stripe will be worn for each five years of service; motormen will wear silver braid; conductors, inspectors, starters, etc., gold; emergency linemen, scarlet, and switchmen and subway watchmen, green. A number of the large street railway systems throughout the country are introducing service stripes for employees.

The Traction Company Centennial Band, which is a social organization of employees of the Toledo (Ohio) Traction Company, gave a very successful and enjoyable entertainment recently. The band, which consists of twenty-five good musicians, rendered a musical programme, after which a dance was given. Thomas H. McLean, general manager of the Toledo Traction Company, was present, and with Mrs. McLean led the grand march. Refreshments were provided at the expense of Mr. McLean.

The new electric line from Elkhart to Goshen, Ind., which is owned by the Indiana Electric Railroad Company, was opened on Dec. 19. There now remains only a ten-mile stretch between Elkhart and Mishawaka to give a continuous line of 40 miles from Goshen to South Bend, Ind.

The Cicero & Proviso Street Railway, of Chicago, Ill., was granted a fifty-year franchise by the Cicero Town Council on Dec. 20. The companies to be benefited by this ordinance are the Cicero & Harlem Street Railway Company, Cicero & Proviso Street Railway Company, Ogden Street Railway Company, Suburban Railway Company, and the Chicago Telephone Company.

The Third Avenue Railroad Company, of New York, for the quarter ending Sept. 30, 1898, reports gross earnings of $594,807, as against $699,052 for the corresponding quarter of 1897, and $726,980 in 1896. This is a diminution in gross earnings of $104,245 during the past year, and of $132,173 during the last two years. The net earnings, after paying operating expenses, were $243,221 in 1898, as against $338,790 in 1897, and $377,040 in 1896, and the surplus for stock, after paying charges, is $150,827 in 1898, as against $246,970 in 1897, and $290,261 in 1896.

The annual report of the Railroad Commissioners for the State of Maine for the year ending June 30, 1898, shows an increase in gross earnings in 1898 over 1897 of $49,342. The Portland Railroad Company earned the largest sum per mile of road, $9,762, and the Augusta, Hallowell & Gardiner Railroad Company operated its line at the lowest percentage of operating expenses to earnings, 54 per cent. Only one person was killed and but thirteen injured by the street railways of the State during the year, seven of the latter being in a single collision, and the other six from their own carelessness, nearly all in getting on or off cars while in motion.

The just issued report of the Railroad Commissioners of Connecticut for the year ending June 30, 1898, shows that the capital stock and funded and floating indebtedness of the street railways of the State amount to $51,610 per mile of road. The largest capitalization per mile is that of the Meriden Electric Railroad Company, $92,507. The average gross earnings per mile of road operated were $5,254, and per mile run were $.1945. The largest earnings per mile of road were made by the Fair Haven & Westville Railroad, $12,460, and the largest earnings per car mile were made by the Waterbury Traction Company, $.2698. The largest operating expenses per car mile were $.171, those of the Norwich Street Railway Company, and the smallest were $.0856, those of the Bridgeport Traction Company, the average for the State being $.1271. But ten people were killed by the railways of the State during the year, and 128 injured. The capital stock was increased by $680,600, and the bonds by $930,000 over the totals of the previous year. The gross earnings were reduced by $607,242, and the net earnings by $242,328. The dividends were reduced by $85,350, and the interest paid, by $143,852.

A syndicate has acquired, for $1,472,000, the entire street railway system and street railway concessions in Havana, Cuba. It is officially stated that the owners of the Metropolitan Street Railway Company, of New York City, are largely interested in this deal, and that the work of giving Havana one of the finest street railway systems in the world will certainly be commenced in the spring, or as soon as certain minor legal details are settled.

The Union Elevated Railroad, of Chicago, which operates the loop terminal, held its annual stockholders' meeting on Dec. 5, and re-elected directors. No financial statement was given out, but the result of operation for the year ending Nov. 30 is locally estimated as follows:

Revenue from 23,556,000 passengers on the Metropolitan road at one-half cent	$117,780
Revenue from 18,702,000 passengers on the South Side road, at one-half cent	93,510
Minimum charge, Lake Street line	62,500
Minimum charge, Northwestern line	62,500
Total earnings	$336,290
Interest on bonds	$210,000
Surplus on stock	$126,290

This surplus is equivalent to about 2.5 per cent upon the stock.

The ordinance extending the franchises of the Chicago City Railway Company for fifty years has been defeated in the Council.

S. Dana Greene, who is head of the sales department of the General Electric Company, and who served on board the "Yankee" in the Spanish-American War as lieutenant (junior grade), has been detailed for duty as aide to Governor-elect Roosevelt, at the latter's request. Lieut. Greene now occupies the position of lieutenant commander in the naval militia and chief of staff to its captain. He comes from an ancestry, direct and collateral, distinguished in the army and navy of the United States. He is the son of Captain S. Dana Greene, who was first lieutenant of the "Monitor" when she fought the "Merrimac," and who was in charge of her during almost the entire engagement, owing to the accident to Commander Worden. His grandfather, General George S. Greene, is the oldest living graduate of West Point, and his uncle, Major-General Francis Vinton Greene, U. S. V., is in command of the Seventy-first Regiment New York Volunteers.

The officers of the First Regiment of United States Volunteer Engineers gave a dinner on Dec. 8, at Sherry's, New York, in honor of their colonel, Eugene Griffin. Most of the officers of the volunteer regiment were present. Lieut.-Col. Hodges acted as toastmaster, and with a few well-chosen words presented Col. Griffin with a handsome silver loving cup from the officers of the regiment. In acknowledging the souvenir, Col. Griffin reviewed the work of organizing and equipping the regiment, and mentioned the efficient services performed by the engineers in Porto Rico. The latter work included a detailed topographical survey of the main highway of the sea through Ponce to Aibonito; a survey of the Aibonito Pass, showing the locations of the Spanish batteries and entrenchments; a detailed hydrographical survey of the harbors of Ponce and Guanica; a rebuilding of several fine masonry bridges, and the building of a dock and commissary storehouses. An ice and refrigerating plant, a reservoir and a fort were also erected by the regiment. Following Col. Griffin's speech, a number of other addresses were made, and steps were taken looking to a permanent organization of the officers of the engineer regiment.

Important Changes in the General Electric Company

W. J. Clark, of the General Electric Company, has accepted the position of general manager of the company's foreign department, with headquarters in New York.

In the reorganization of the foreign department, D. Mazanet, who, for five years, has held the general managership, and who has piloted it from its small beginning to its present position as one of the foremost departments of the company, becomes managing director of the Mexican General Electric Company, with headquarters in the City of Mexico.

In view of the importance which our recent foreign acquisitions and our improved relations with foreign countries, will give to our commerce, especially in the field of electrical development, the scope of the foreign department will necessarily be greatly widened, and this department will undoubtedly become the foremost in the company. It will have charge of commercial relations between the General Electric Company and all countries outside the United States.

Mr. Clark's wide experience in foreign commercial matters peculiarly fits him for his new position. He has traveled through

Europe, as well as in the countries south of us, and his familiarity with foreign methods and manners will stand him in good stead. His book, "Commercial Cuba," recently published, is already generally acknowledged to be the standard authority on Cuban commercial affairs. He will be greatly missed from the railway department, in the management of which he made a unique record, and his hosts of friends in the American street railway field will regret to hear that he is no longer to be in active charge of the home business.

Americanizing a Railway in Porto Rico

The incorporation in Albany on Dec. 27 of the San Juan & Rio Piedras Railroad Company, with a capital of $300,000, brings to a focus an interesting enterprise which has been carried out by a syndicate organized by the well-known engineering firm of J. G. White & Company, to obtain a foothold in the transportation industry of Porto Rico. Some months ago Mr. Young, an engineer connected with this firm, was sent to Porto Rico on a tour of investigation, and found a valuable railroad property, seven miles in length, connecting San Juan with a rich residential district, practically the only one in the city. An option was secured by Mr. Young, and the property was shortly after purchased by the White syndicate.

This road was formerly owned by Mr. Pablo Ubarri, a Spaniard, resident in San Juan, and was originally built as a steam road in 1880. The line extends from a point near the center of San Juan, to a distance of seven miles through the suburban territory of Puerte de Tierra and the residential suburbs of San Tource, Martin Peña, and Rio Piedras. The entire Rio Piedras district has about 12,000 inhabitants, but the town proper has about 3000, and contains the Governor's summer palace. The railroad, as constructed, runs along the side of the main military road, extending from San Juan to Ponce, but is separated from it by well-defined embankments, and is upon its own right-of way, so that practically any desired speed can be made without difficulty. The present gage is about 30 ins., and many of the ties that have been down for eighteen years are still in good preservation, being of the native hard woods of the country.

The new company proposes to widen the gage of the road, to electrify the same in the best possible manner, and also to extend the road by a loop around the principal plaza in San Juan, and when the new work is completed and modern cars are operated at frequent intervals it is expected that the line will be largely patronized. The company also has in view still further extensions and improvements, which make this railroad a most important one for San Juan and the island of Porto Rico. It likewise contemplates furnishing electric lights along the line of the road.

This steam road was purchased and taken over on Nov. 26, 1898, and has been operated by Messrs. J. G. White & Company, who are, as before stated, managers of the syndicate which secured and are promoting the enterprise. The incorporators of the new company are George H. Walbridge, Fernando G. Echeverria, H. H. Harrison, Edward Schmidt, Lathrop R. Bacon, F. Kingsbury Curtis, Philip H. McMillan, Augustus N. Hand and William B. Parsons, of New York City.

Consolidation Negotiations in Several Cities

Early in December a syndicate, headed by Alexander Brown & Sons, prominent bankers of Baltimore, and said to include the powerful New York and Philadelphia capital interested in the street railways of those two cities, made an offer to purchase the $3,500,000 capital stock of the Baltimore City Passenger Railway Company at a price of $90 per share, the shares being $25 par value. Acceptance of this offer was recommended to the stockholders by the president and directors of the Baltimore City Passenger Railway Company, and there is no doubt of the stockholders' decision. As a result of this purchase there are now two large competitive street railway systems in Baltimore—the Baltimore & Northern and the Baltimore Consolidated. The former owns about 135 miles of track and the latter 207 miles. There are now outstanding $9,172,000 of the capital stock of the Baltimore Consolidated Railway and $10,550,000 of its bonds, while of the Baltimore & Northern system there are $4,700,000 in outstanding bonds and $1,400,000 in outstanding stock, exclusive of the $3,500,000 of Baltimore City Passenger stock now purchased for the sum of $12,600,000.

About ten days after the above purchase was made it was officially announced that an agreement had been reached between the Baltimore Consolidated and the Baltimore & Northern companies for a general consolidation of the entire street railway system of Baltimore, but shortly after this a disagreement taking place before the final merger of interests, the consolidation was not effected.

The Brown Syndicate is known to include Harry Parr and G. R. Webb, of Baltimore, and Sidney Wright, of Philadelphia, while the Elkins-Widener-Dolan interests are believed to be also associated with Mr. Brown.

Another important street railway purchase, amounting probably to eventual consolidation, has taken place in St. Louis during the past month. It will be remembered that last summer a new company, the Central Traction Company, obtained a franchise to build about eighty miles of track in St. Louis. This franchise was passed by the Municipal Assembly, was vetoed by the Mayor, and was passed over his veto. It was extremely valuable, as it gave the new company the right to lease the tracks of any other street railway, and, in effect, to bring about a consolidation. It soon developed that the parties behind this new company were the Elkins-Widener syndicate, of Philadelphia, and Sellers McKee, of Pittsburgh.

On Dec. 7, the National Railway Company, of Chicago, which owns seven street railway properties in St. Louis, sold and transferred those properties to local capitalists, Messrs. Spencer & Orthwein, who had previously, about two years pefore, purchased the Southern Electric Railway property. Up to the present time it is not known whether these two gentlemen bought the stock for themselves or bought it on account of Eastern capitalists, but it is significant that at almost the same time, Messrs. Brown Brothers, of New York, who are closely associated with the Elkins-Widener syndicate, purchased or secured an option on the stock of the Lindell Railway Company, the general understanding in St. Louis being that the road has been sold. It is believed that the Eastern syndicate now controls every street railway in St. Louis except the Union Depot line, and that there is simply a question of price in negotiations for the latter.

In connection with these attempts at street railway consolidation there appear to be movements on foot in New York City, Brooklyn, Philadelphia, Baltimore, Pittsburgh, St. Louis and Chicago, to effect general consolidations of electric lighting, gas and street railway properties with a view to introducing economies in management, to utilize the waste products to better advantage, and to operate power stations with more economical load factors. It is now known, for example, that the New York Light, Heat & Power Company, recently organized, with a capitalization of $25,000,000, has been, and will be, closely associated in interest with the Metropolitan Street Railway Co. It has purchased the Empire Conduit Company, which has the monopoly of high-tension underground conduit system in the northern part of Manhattan Island, and the Mt. Morris Electric Light Company, and the surplus power of the new 70,000-h.p. station which the Metropolitan Company is building will be used for lighting purposes, together with many of the ducts now being laid in such quantities on the company's north and south railway lines.

Electric Equipment in Silesia, Germany

The Electricitats Gesellschaft Felix Singer & Co., Aktiengesellschaft, of Berlin, has recently received a contract from the Ober Schlesischedampf Strassenbahn-Gesellschaft for twenty electric motor cars with eighty motors for a gage of 785 mm. These will be used on some future extensions of this railway. This order makes a total of 208 motors which the Ober Schlesischedampf Strassenbahn-Gesellschaft has purchased from Felix Singer & Co.

Calendars for 1899

The coming of the new year has brought the usual number of calendars, but of a greater variety and more attractive than ever before. The number issued is extremely numerous, but some which have been already received deserve special notice. The most elaborate calendar this year is, without doubt, that issued by the Falk Manufacturing Company. This is a collection of six beautiful reproductions of well-known paintings, each accompanied by a calendar for two months. With this is a short story of each of the pictures by Prof. H. Ward Rhodes, Museum of Fine Arts, Washington University. The pictures are printed with a tint on heavy cardboard, and are extremely tasteful. The Okonite Company has also recently published an attractive calendar bearing handsome colored pictures. A beautiful calendar has also been issued by the American Electrical Works, of Providence, R. I., and others are being received with each mail.

Trolley Wheel for High Speed Roads

A trolley wheel especially designed for high speed roads, but also adapted for any kind of trolley road, has been put on the market by the Star Brass Works, of Kalamazoo, Mich., and is known as the Kalamazoo wheel. The peculiar feature of the wheel is that it will lubricate itself and is soft enough not to injure the overhead work. The hub is cast hollow and is filled with oil, which lubricates the bushings. All the long distance lines running out of Detroit are using this wheel. This service is a severe one, as a car is run from 30 to 40 miles an hour for long distances. The metal in the wheel is treated for electrical purposes by a method owned and controlled by the Star Brass Works, and gives, it is claimed, excellent results and entire proof against sleet. The wheel is supplied in a harp of special design, so made that the harp will not catch on anything in case the trolley leaves the wire.

Contracts Awarded by the Third Ave. Railroad Co.

A description was published in the last issue of the STREET RAILWAY JOURNAL as to the plans of the Third Avenue Railroad Company, of New York, for electrical equipment, and mention was made of a number of contracts. During December a number of other contracts were awarded by the company, including that for the steam plant and electrical apparatus. Bids were submitted by the different electric companies on specifications drawn up by Dr. Louis Duncan, consulting engineer of the company, and the contract was given to the Westinghouse Electric & Manufacturing Company, who will furnish all the electrical apparatus from its own shops; the Westinghouse Machine Company will furnish the engines, while the Westinghouse, Church, Kerr & Co. will execute contract for the construction of the entire steam plant. The total contract amounts to about $5,000,000, more than half of which is for the steam plant, and this does not include the building or the substructure on which it stands. Westinghouse, Church, Kerr & Co. are the engineers and architects for the building and furnished complete plans and specifications by which the contract will be let.

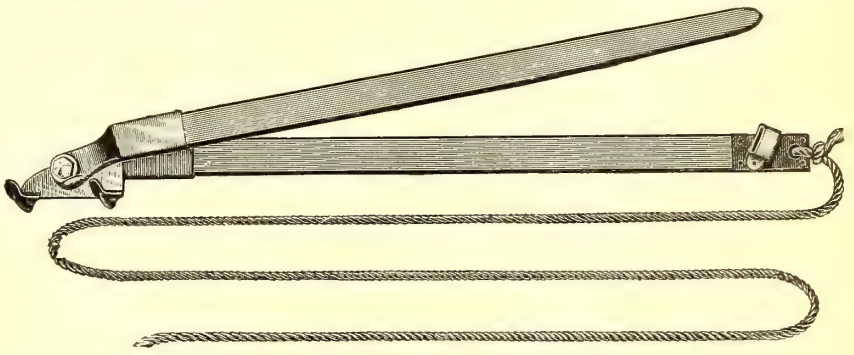
The power station for supplying current to all the lines of the Third Avenue Company, which comprise over 100 miles of track, will be on the Harlem River, between 216th Street, Ninth Avenue and 218th Street, and the distribution will be made at high tension to substations located in different parts of the city. The power house will be approximately 320 ft. long and 250 ft. wide, and will contain sixteen 3000 kw. alternating current generators, which will be driven by engines having a mechanical rating of about 4000 h.p., but a maximum capacity of at least 50 per cent over this. Thus the station will have a nominal rating of 64,000 h.p. and a maximum capacity of about 100,000 h.p., and is undoubtedly the largest station ever projected. The engines will stand in double rows in the engine room, 320 ft. long.

The boiler house will stand parallel to the engine house and will contain a double row of Babcock & Wilcox boilers in two decks. These boilers, if set in continuous battery, would be about 1000 ft. long. Coal will be received from an enormous coalbin overhead, from which the fuel will chute to the Roney stokers, with which the boilers will be equipped, and the ashes will be drawn from the hoppers under the boilers. The boiler plant will be generously supplied with economizers and the draft will be handled by a combination of natural and mechanical draft on a system more complete than has ever yet been installed, and involving the use of four tall stacks. The condensing apparatus will be so arranged that the engines will be served in sections, with special provisions for handling this part of the service with greater economy and reliability. The method of piping is most complete, and with numerous provisions for all contingencies.

Aside from the sixteen large generators, there will be much other electrical apparatus in the power station, including an enormous switchboard about 200 ft. long, exciting apparatus with separate switchboards, rotary transformers, not including the various substations throughout the city, all the apparatus for which will be furnished by the Westinghouse Electric & Manufacturing Company. In addition to the power station and substation apparatus, all the car equipment will also be supplied by the Westinghouse Company.

Spring Liner for Track Rails

The wisdom of employing a spring liner for track rails to relieve the anvil effect noted in rigid roadbed construction is already apparent in the new track construction of the Third Avenue (New York) Railway Company. The new construction, which was illustrated and described in the December issue of the STREET RAILWAY JOURNAL, has been completed from 124th Street as far south as Seventy-fourth Stret, and the striking contrast in the effect upon the car and rail is instantly noticed by the most unobserving passenger as the car passes from the old to the new section. The rumbling and bumping sound is eliminated and the cars ride with a most agreeable motion, as if one were floating in a boat on the surface of placid water. The result in the life of the rail will be watched with a great deal of interest, as the old rail, which was a 7-in. grooved girder, has been so hammered out as to be unfit for legitimate service, and this after a life of less than five years.



Railway Building Near Detroit

Of the many roads which go to make up the chain of interurban systems around Detroit a considerable number were constructed by the International Construction Company of that city, who certainly can feel a just pride in their record in Detroit. During the year 1898 this company contracted for the complete construction and equipment of the Detroit, Lake Shore & Mt. Clemens Railway, Detroit & River St. Clair Railway, Detroit, Plymouth & Northville Railway and the Mt. Clemens & Lake Side Traction Company. All these lines are in actual operation, or soon will be, and their aggregate length is over 80 miles. The companies were also largely financed by the International Construction Company.

The International Construction Company was also contractor for the Mill Creek Valley Street Railroad from Cincinnati to Hamilton, Ohio, and for the year 1899 has a large amount of work on hand, not only in the city of Detroit, but over the entire country. The company's offices occupy five large rooms in the Chamber of Commerce, and its drafting and engineering departments occupy three more rooms.

Trolley Wire Emergency Clamp

The accompanying engraving shows an emergency clamp or pickup manufactured by the Western Electrical Supply Company, of St. Louis, and used to handle broken trolley or other live wires. The handles are made of hard wood, which gives perfect insulation. Attached to the handle of this device is a piece of rope about 20 ft. long, which enables the conductor of the car to replace broken wire where it will be harmless until the linemen can place it in its proper position. For this purpose one of these clamps should be carried on each car.

TROLLEY WIRE EMERGENCY CLAMP

Line Material

L. A. Chase & Co., of Boston, will hereafter control the sale of "Pawtucket" line material. This material has a high reputation and is the standard on many roads. Notwithstanding the high grade of this material, Chase & Co. claim to be able to market it at prices generally obtained for the cheapest grades. This is due to the unsurpassed facilities for manufacturing this material.

The Electrical Exhibition Company has, at a meeting held Dec. 7, decided to conduct another electrical exhibition at Madison Square Garden during the month of May, under the auspices of and in connection with the twenty-second annual convention of the National Electric Light Association.

Switchboard Instruments for Street Railway Generator Panels

The selection of indicating instruments for the generator panels of a street railway switchboard is a matter of as great, if not greater, importance than the selection of the instruments for the feeder panels. The latter subject was discussed in the November

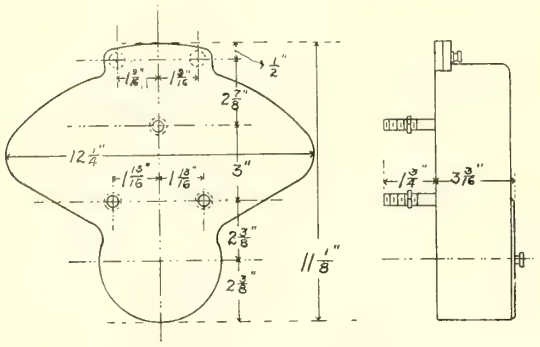


DIAGRAM OF VOLTMETER

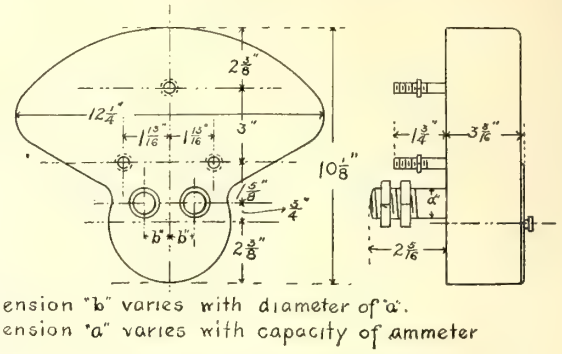

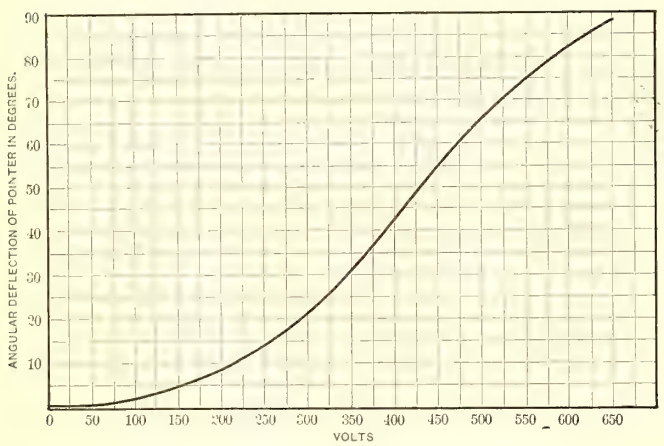

DIAGRAM OF AMMETER

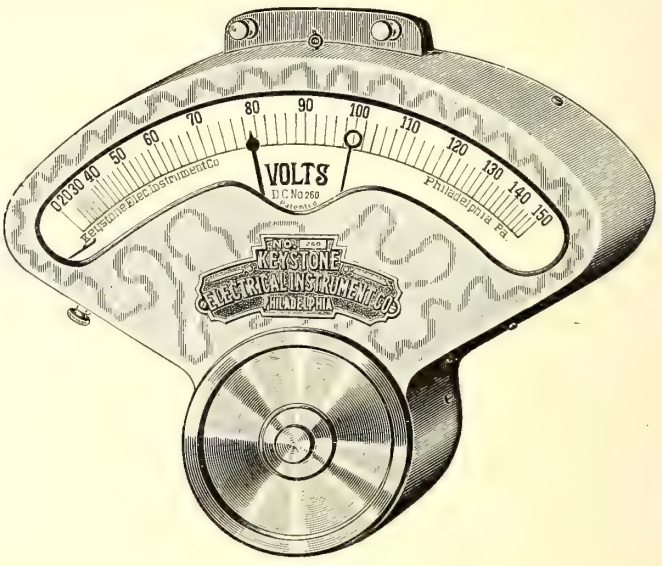
issue, and much that was said in connection with feeder ammeters applies equally well to generator or summation ammeters. The principle employed in both cases is the same, the major difference being that of range, since one generator frequently supplies many feeders.

On the generator panel, however, it is the voltmeter, rather than the ammeter, which occupies the position of prime importance. The voltmeter indicates the potential of the generator, and, by proper deductions for line drop, the potential at the terminals of the car motors. Since street railway systems are invariably operated on the constant potential system and any abnormal variation of potential is followed by more or less serious trouble, it is important that the generator voltmeter should be accurate, durable and dead-beat, and if it lack any of these attributes it is not adapted for railway use.

To meet these requirements the Keystone Electrical Instrument



CALIBRATION CURVE OF VOLTMETER

Company, of Philadelphia, placed on the market, some years ago, a line of instruments designated by them as its Type "K." The engravings presented herewith show the external appearance of this type of instrument and, diagrammatically, its dimensions. As may be noted, the case is of graceful design and the scale long, with clearly marked and open divisions around the normal working point. The scale shown is that of an instrument reading to 150 volts, but if each scale division is multiplied by 4 it will represent its appearance when calibrated for a maximum potential of 600 volts. The finish of the case is brass, grained and lacquered by hand.

The system employed in the voltmeter is electro-magnetic, a system concerning which much has been written pro and con, but which has survived all attacks made upon it, and to-day is recognized as the one which, if scientifically designed and properly constructed, meets the exacting requirements of modern engineering practice. The general principle of the voltmeter and the methods employed in its construction and calibration, follow the lines laid down previously for feeder ammeters. Careful provision is made to protect the instrument from the influence of external fields, and the design is such that variations of temperature produce no variations in indications. This latter point is accomplished by employing a special alloy wire in the instrument, the temperature coefficient of which is negligible, and, in addition, providing a generous area of cross section, so that there can be no perceptible heating in the windings of the instrument due to the flow of the very small actuating current.

Calibration is effected by comparison with a standard voltmeter which never leaves the laboratory, and this standard is kept in absolute check by the galvanometer, bridge and standard cell method, now so well known in laboratory practice. In alternating current work comparison is made with a standard voltmeter employing the dynamometer system, and the windings of the switchboard instrument under calibration is so carefully proportioned between inductive and non-inductive resistance that errors due to self-induction and capacity, under normal variations of frequency, are quite negligible. Absolute compensation for any variation of frequency may be obtained by the employment of an inductive shunt across the terminals of the actuating solenoid. This method is described in a patent recently issued to the Keystone Electrical Instrument

VOLTMETER

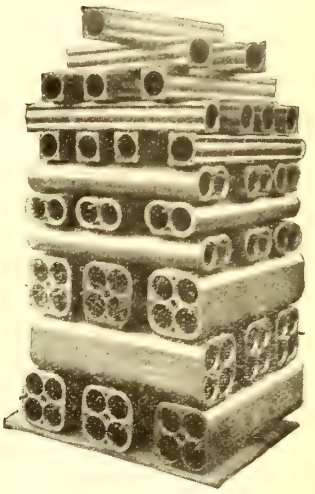
Company, and provides for compensation between direct current and alternating current of any frequency.

One of the most important features in any indicating instrument is the curve of calibration, and attention is called to the curve shown herewith which was taken from a voltmeter now in use, calibrated for a total potential of 650 volts. From this curve, it will be noted that the lower portion of the scale is suppressed, and the calibrated portion, or working range, is from 100 to 650 volts. Values below 100 volts are never used in practice, and the suppression of this portion of the scale permits wider divisions around the normal working point. The curve is fair and follows accurately known laws with a total absence of irregularities. This last point is of prime importance, for an irregular calibration curve indicates arbitrary calibration and a system improperly designed or proportioned. Such a system is sure to give inaccurate results and to possess inherently objectionable features.

The calibration curve of any instrument can be found by removing the scale plate and finding the center, from which the arc of the circle forming the base of the division lines is described. Then by plotting the angular distance between the division lines, ex-

tended to the center, as ordinates with their coresponding values in volts as abscissae, the curve may be laid down.

Generator ammeters and summation, or total output, ammeters may be constructed on either the series or shunt principle, depending on the current to be measured and the local conditions governing the construction of the switchboard. For alternating current of large volumes the series transformer presents many advantages. This series transformer consists of a primary of one turn, cut in on the bus-bar and clamped or bolted to it, and a secondary of a number of turns of finer wire. The ammeter is connected across the terminals of the secondary and receives a current of from 10 to 25 amps. with a drop of a small fraction of a volt. The total current in the secondary circuit of the transformer is so proportioned to the current in the primary circuit that the effects of self-induction and capacity balance one another, there being sufficient current in all cases to provide ample force to properly actuate the ammeter system. The ratio of the current in the primary to that of the secondary in this series transformer must, however, be carefully determined under variations of load and variations of frequency, and these adjustments are always made by the instrument maker, then the ammeter can be calibrated in terms of the primary, or bus-bar, current.



Voltmeters for high tension alternating current should be placed in the secondary of a regular step-down trasformer, which accurately transforms the bus-bar potential to a working potential of from 100 to 120 volts. All voltmeter transformers should be carefully tested by the instrument maker to determine their exact ratio and their variation, if any, under varying frequency and varying primary potential.

It is now considered good practice in high potential alternating circuits, using two or three phase transmissions, to place an independent voltmeter in each leg in order to obviate the dangers and annoyances incident to switching such high potentials on one instrument by means of a voltmeter switch when reading the voltage of each leg.

Modern practice in electrical engineering demands of each piece of apparatus employed in an installation accuracy, efficiency and durability, and if these are of importance in the generating, transmitting and translating devices, they are of far greater importance in the measuring instruments employed to determine them. Great care should be exercised in the design and construction of measuring instruments, and an equal amount of care and thought should be given by the designer of the plant to the proper selection of this important part of his installation.

TERRA COTTA CONDUITS READY FOR SHIPMENT

ONE, TWO AND FOUR-DUCT CONDUITS

The Manufacture of Terra Cotta Conduits for Electric Wires

Terra cotta, or baked clay, is one of the most enduring substances known, as the clay tiles and tablets from the ruins of ancient temples testify, being found by recent explorations in a perfect state of preservation. It is interesting to note in this connection how the potter's art, the most ancient of all arts, is now contributing to the safe and successful use of electricity, the most recently developed of nature's forces.

It is not the province of this article to tell how all conduits of this character are produced, but only as found in the works of the Potomac Terra Cotta Company, which are located at Terra Cotta, four miles out from Washington, D. C., on the line of the Baltimore & Ohio Railway. The plant includes clay beds, whence the material is mined, an extensive building for housing the machinery, and drying floors and kilns for the burning and vitrifying. The surface of the region is abruptly rolling, and the clay deposits, which are seemingly inexhaustible, are found in irregular veins located from a few to several feet below the surface, appearing to have been thrown up from a lower level by some internal upheaval. The deposit is in streaks of red and white, the red predominating, and in process of mining nuggets of iron ore are frequently found, ranging from a few ounces in weight to several hundred pounds. The method of mining is simple, as it is only necessary to remove the layer of gravel and sand, which covers the clay, which is very hard and dry, so that it is readily broken from the face of the vein by means of heavy iron wedges. The material, which is in lumps of various sizes, is transported a short distance to the mill in tram-cars or carts, and is dumped directly into a hopper at the side of the building, which is located against a bank, so that the road is slightly above the basement floor. From the hopper the material falls directly into a grinding mill, which consists of an open trough, about 10 ft. long, in which revolves a horizontal shaft. The latter is provided with heavy radial knives placed spirally, which cut or pulverize the lumps into smaller grains, and discharge the material at one end after the manner of a spiral conveyor. From this the material falls upon a belt conveyor, by which it is elevated to the grinding mill, and as it passes along the conveyor an attendant picks out from the mass all lumps of iron or stone.

The grinding mill consists of a rapidly revolving cylinder with grooves cut lengthways in the surface, and reduces the material still finer. From this mill the material drops directly into a pair of chilled crushing rolls, which are spaced less than 1/16 in. apart, and serve to crush the material into a fine powder. From this machine a belt conveyor distributes the clay along the floor of the basement of the building, when it is moistened by means of a hose, and piled up against the side walls, where it is left from five to seven days, or until thoroughly soaked or "tempered," which is the term employed. The amount of moisture depends upon the character and size of the product to be moulded. For instance, the material for large sewer pipe sections is necessarily more plastic than for smaller pieces. When sufficiently tempered the clay is delivered to the pug mill, which consists of a steel cylinder 8 ft. in length and about 18 ins. in diameter, in which is a revolving shaft carrying, over most of its length, spiral knives, and near the end a beater, which is similar to the flukes of a propeller. This serves to force the clay through the cylinder, and as the material emerges, the mass is sliced up by means of revolving knives, which run parallel to the end of the cylinder; from this the clay is immediately taken up by a bucket conveyor, and lifted to the top or third floor of the building, where, by means of short belt conveyors, it is conveyed to the cylinders of the forcing presses.

There are two vertical presses in which the steam cylinder is placed directly above the cylinder which receives the plastic mass. Three piston rods convey the power from the steam cylinder to the head of the press; the steam cylinders in each press are about 3 ft. in diameter, and have a stroke of about 4 ft., and operate under a pressure of 120 lbs. The diameter of the forcing press is from 20 ins. to 30 ins., and the material is fed in at the side after the follower is lifted. Suitable dies are attached to the base of the forcing cylinder, depending upon the character of the product. For making the four-way ducts the four dies are attached to a suitable interior frame-work, and are each about 12 ins. in length, cone shaped to within 3 ins. of the lower end, for which distance they are uniform in diameter, either 3 ins. or 3¼ ins., depending upon the size of the duct required. There are also rods placed in the dies, which serve to form the cavities designed for the dowel pins, and also for the small central duct. The conduits are made in one, two and four-duct sections, and are usually about 30 ins. in length. The four-duct sections when burned weigh about 80 lbs.

Sewer pipe, of sizes, up to 30 ins., is forced in the same manner, the dies being rounded off on the inner surface, so that the material spreads out and emerges in a perfect ring, which is cut into any desired length. In the process of forcing the sewer sections or conduits, a balanced platform, carrying a square board, known as a "shod," is placed directly under the die, which descends by the weight of the section as fast as it emerges from the die. When of sufficient length it is cut off by means of a wire, when the section still standing on end is transported to the drying floor. The sewer sections are readily shifted about the floors by means of long-handled trucks with small wheels. These trucks have, at their outer extremity, in line with the handles, iron bars bent in such shape as to be readily slid under the base or shod on which the section rests. Cleats on the under side of the shod raise it sufficiently above the floor to allow the bars of the truck to be inserted, when, the handles being slightly pressed down, the section is lifted, and can be safely shifted about. Flat two-wheel trucks with handles are employed for handling the conduit sections. The two upper floors of the building, which is T shape, one wing being 200 ft. in length, and the other 100 ft., are employed for drying the sections. This process requires from four to six days, steam pipes being attached to the ceiling of both floors to provide a suitable drying temperature.

For turning the sewer sections in the process of drying a semi-circular frame of slats is provided with curved runners on one side, and iron bar extensions on the other. This is called a cradle, and by inserting the bars under the shods on which the section rests the whole is gently lifted and turned on the rockers, end for end. Just before it is placed in position an attendant removes the shod, and puts it at the other end when the section is slid against it, and is brought to an upright position. The operation is performed very rapidly.

As soon as the sections are ready for the kilns they are lowered to the ground floor by means of balanced elevators, with which each floor is served, and the weight of the material as it descends serves to raise the alternate platform, so no power is required for the operation. Three boilers, two of 50 h.p. and one of 125 h.p., provide the steam for the drying processes, also for driving a 100-h.p. Atlas engine, by means of which the grinding machines are operated.

We are now ready to follow the sections of material to the kilns, of which there are twelve, and which are circular, some being 22 ft. in diameter, and others 26 ft., with two 30 ft. All are dome shaped, and bound about by hoops of steel plate 5 ins. in width. One of the newest, a 30-ft. kiln, has the dome finished in steps, and four hoops at the crown. It is built extra strong to support the expansive pressure of the dome, and, it is believed, will last for many years. In the process of setting the kilns the sections are transported from the dry house by means of trucks, or on the shoulders of the laborers, and are placed on end, with one section above another, until the whole interior is filled. The furnaces are placed at intervals in the outer rim of the kilns, and soft coal is burned in them. A double interior flame wall is provided about 6 ft. in height, between which and the outer wall the heat from the furnaces is delivered and passes to the dome, thence downward through the floor into the flues beneath, through which the smoke is conveyed to large chimneys, one of which answers for two kilns. The fire is started gradually and increased until the contents of the kilns are brought to a white heat, and continues from five to seven days, when the fires are removed. The furnace is then sealed up and the material is left for about the same length of time for gradual cooling. Just before the firing process is completed a cheap grade of salt is sprinkled into the furnaces, about a wheel-barrow load being required for a kiln. The fumes of the salt, uniting with the heated clay, serves to glaze the surface of the material inside and out, with the hard, impervious coating which is characteristic of this class of product.

The business of the Potomac Terra Cotta Company was established about twenty-five years ago, and until ten years ago the company was engaged in the manufacture of sewer pipe exclusively. This concern claims the distinction of having been the first terra cotta factory in this country to begin the manufacture of material for electric conduits, and filled its first conduit contract in 1887, the order being from the United States Electric Lighting Company, of Washington. One claim of superiority made by the manufacturers for their conduit which is known as the "Mason" is that of perfect vitrifaction, due to the use of a clay that vitrifies at a high temperature, rendering it non-absorbent, while it is indestructible by the elements when properly made. Another feature, and for which the company owns letters patent, is the provision of minor openings, designed for the reception of iron dowels in the ends, which secure perfect registration of the ducts in the process of laying. The dowels are about ½ in. diameter, and are provided on one side with a barb, which prevents a settling too far into the chambers designed for them. As the conduits are glazed inside, as well as out, little or no friction resistance is offered to the drawing in of the cables, and there is no chafing of the sheath. The conduits are thoroughly burned, have a dark chocolate color, and are unusually strong for this class of material. Being manufactured in standard lengths of 30 ins., they are easily handled, and not liable to breakage in handling or shipping. The affairs of the company are under the direction of George Mason, after whom the conduits are named.

A Handsome Vestibuled Car

The car shown in the accompanying illustration is, perhaps, one of the handsomest electric cars for regular service now in use on any road in New England. It is one of three which have just been built for the Newton Street Railway Company, of Newton, Mass., by the Laconia Car Company Works, of Boston.

The car is 25 ft. over end sills, and 35 ft. over bumpers. It is fitted with vestibules at each end, has reversible seats, and the windows are heavy plate glass, with double sash, similar to those on the finest steam cars. The interior of the car, including the vestibules, is finished in the choicest of mahogany panel work, with mahogany doors. There are eighteen reversible plush seats 32 ins. wide. The car is wired for twelve incandescent lights, and at each window post is a push-button for signaling the conductor. The car is mounted on Brill No. 27 trucks.

CAR FOR NEWTON, MASS.

A New Type of Surface Contact System

The Campbell Electric Traction Company, of Towanda, Pa., has recently put on the market a new type of surface contact system. In this system the conduit, which is about 6 ins. x 9 ins. in cross section, and air and water tight, rests on the top of the ties, and its upper surface is flush with that of the paving. The bottom and sides of the conduit may be of either wood or iron, as preferred. The top consists of 8 ft. metal sections, thoroughly insulated from the rest of the conduit and from each other. The interior of the conduit is hollow, and at the bottom on the inside lies a continuous rail, carrying the 550-volt current. Contact between this rail and the insulated sections on the surface of the street can only be made by a specially designed trolley or traveler that runs in the conduit, and is controlled in its movement by a pair of strong electro-magnets on the car. As the car moves along, the trolley on the inside of the conduit travels at the same rate, being always in position under the magnets at the center of the car. Consequently there can be no live section, except that over which the car is situated.

New Horizontal Engine, with Direct-Connected Generator

One of the latest designs of direct-connected units has been brought out by the B. F. Sturtevant Company, of Boston, Mass. This unit is unusually compact and neat, and has been built with special attention to the requirements of all conditions of service. The frame of the engine with the attached oil guard and removable side plates practically inclose the running parts, prevent the throwing of oil and decrease the annoyance from dust. The valve is of the balanced piston type, with snap rings, and operates in a removable bushing. The regulator, which is of the most delicate construction, secures the closest possible regulation through a range from zero to three-quarters cut-off. Continuous sight feeding arrangements are provided for all bearings. The engine is of the automatic horizontal center-crank type.

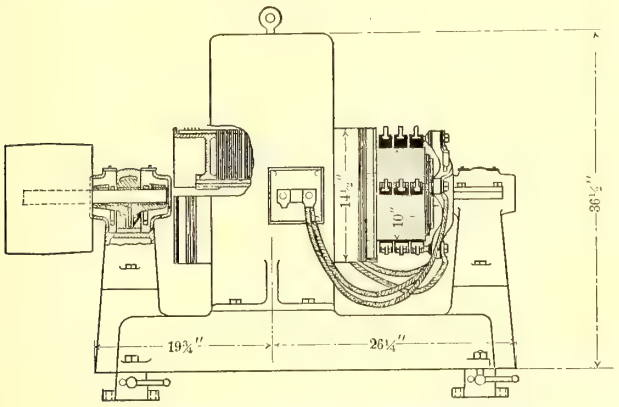


FIG. 3.—SIDE ELEVATION OF GENERATOR

The magnet frame of the generator is of cast steel, and the shaping of the pole pieces and proportioning of magnetic field and armature is such as to insure absolutely sparkless operation under all changes of load, from no load to 25 per cent overload. The temperature rise after a full load run of ten hours is guaranteed not to exceed 90 deg. Fahr. The bearings, which are ring oiling, are built upon the ball and socket principle.

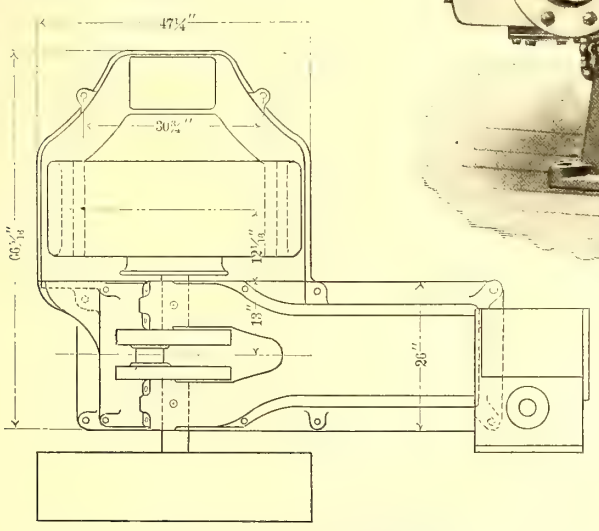

FIG. 2.—PLAN OF DIRECT CONNECTED UNIT

In Fig. 1 is shown the Sturtevant horizontal center-crank engine direct-connected to a four-pole generator. This unit is built with the engine cylinder of various sizes, ranging from 6 ins. x 8 ins. to 13 ins. x 12 ins. These are standard combinations, but any special combinations can be made to meet any requirements. Fig. 2 shows a plan view of a 11-in. x 10-in. horizontal engine connected to a 30-kw. generator. Fig. 3 shows the side elevation of the Sturtevant M P-4 generator. This unit is provided with a substantial bed, which serves to render the entire foundation extremely rigid.

The Thompson-Walker Surface Contact System

This system has been worked out by Prof. S. P. Thompson, the well-known writer on electrical subjects, in connection with Mr. Miles Walker, and upon invitation, an experimental line at Willesden was recently inspected by F. H. Fernie, representative of the STREET RAILWAY JOURNAL for Great Britain. The line is about 200 yards in length, and contains a sharp grade and curve. The electro-magnetic system is employed, as shown diagrammatically in Fig. 1, the magnets being excited by a piece of iron carried on the car. To understand the principle employed, some preliminary explanation is necessary.

If an iron plungeboard with extended ends like No. 2, in Fig. 2, is surrounded by a solenoid of wire carrying the current, it is possible to choose the size of the heads so that the tendency of the plunger to assume a central position is balanced by the attraction of the solenoid on the iron heads. With properly chosen heads the solenoid exerts no force whatever on the plunger. Gravity being the only force upon it, it will, of course, take up the position shown. If now a piece of iron is placed over it, as shown in No. 3, the plunger may be raised by the attraction between the two. In case a very heavy plunger is used it is possible to support part of its weight by merely increasing the size of the lower head by a small amount. It is thus possible to construct a simple piece of mechanism whose movement is entirely dependent upon the presence of a mass of iron in its neighborhood, and which cannot be moved by the solenoid itself, even though the magnetizing current carries the iron up to the saturation limit. This has been converted into the operating part of the switch.

Though the force of attraction is sufficient to lift a fairly heavy plunger and operate a switch, it is desirable to have something more than this, i. e., a switch which will, notwithstanding its massive moving parts, close in an exceedingly short space of time, as well as a very great acceleration upon the moving parts during the first part of their motion. This is obtained by the inventors by merely separating the upper head from the plunger by a short air-gap, and arranging matters so that the mass of iron comes over the switch before current is put through the magnetizing coil. As soon as current passes, the attraction upon the head is so great that the plunger gets up a high velocity before the two come together, with the result that the switch operates as though it had been hit with a hammer. A very simple device, a mere film of oil acting as a cushion, can be employed to prevent the switch from being injured by the concussion.

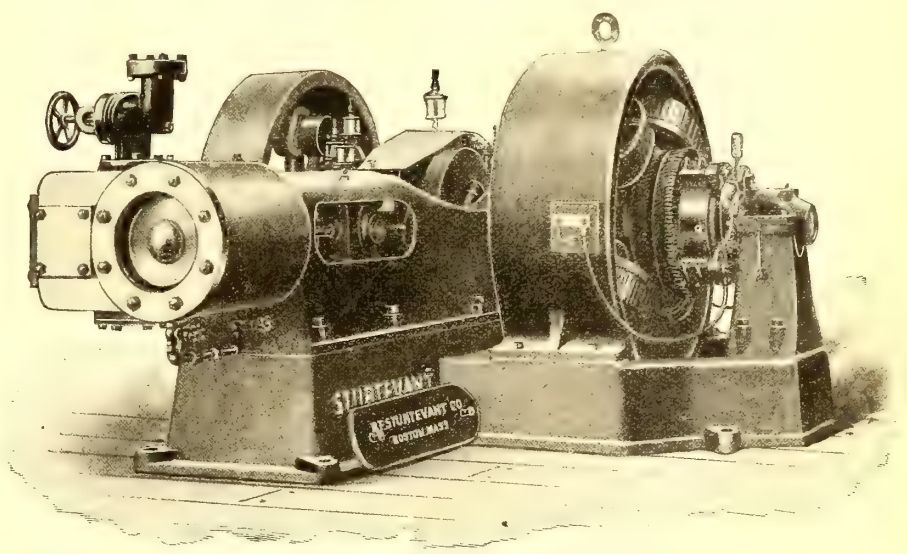

FIG. 1.—DIRECT CONNECTED UNIT

The connection of this operating part to the contact points of the switch has been the subject of some very varied experiments. If the safety of the street passengers could be made dependent upon nothing else than the falling of the plunger when the mass of iron is removed, it was thought by the inventors that as great perfection would be attained as could be hoped for from any moving mechanism. The attachment of any gear at once introduces the risk of friction and the simplicity of the issue is destroyed. For that reason, as well as for cheapness and convenience, the method shown in Fig. 3 was decided upon, though there are some simpler modifications of it still under experiment. The diagram, which is intended to illustrate the principle only, shows, in the first place, the cast-iron box which is laid in the street. This is surrounded by a gunmetal stud *S*, faced with a phosphor--bronze wearing cap.

This stud is insulated from the iron box by a sheet of micanite. A non-porous road material is placed around the stud to make up the level.

The box is filled with oil, which besides performing the function presently to be considered, maintains very high insulation throughout. The switch is attached to the stud and comes away with it in one piece. Being only about 4 ins. in diameter no difficulty is found in making a perfectly watertight joint.

The next point to consider is the method of making electrical contact. The requirements of switchpoints for disconnecting surface-studs are given by the inventors as follows: When closed the contacts should be of low resistance and capable of carrying 100 amperes easily. They should be incapable of fusing or sticking in any way, and should require only a small force to operate them. They should retain their shape and efficiency unimpaired for a long time without requiring attention. It will be observed that the current through the stud ceases as soon as the skate parts company with the stud as the car moves forward. Hence in the operation of the car as the switch-plunger falls it does not have to break the main current, that having already ceased. Yet although the switches are not required in the ordinary course to break a large current, it is desirable that they should be able in case of accident to do so without injury. After experimenting with different forms of contact it was found that nothing fulfils these requirements so completely as a properly designed mercury contact. Mercury contacts are, therefore, used throughout these switches.

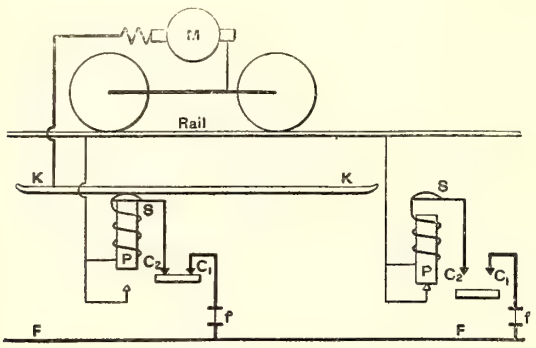

FIG. 1.—DIAGRAM OF CIRCUITS

The yoke of copper which dips into the mercury is supported by a brass tube which floats in the oil and fits loosely into a fixed brass tube which acts as a guide. When the plunger rises it takes the oil from under the float, which accordingly falls and connection is made. When the plunger falls the float rises. As the plunger moves quickly the oil has not time to leak past the sides, notwithstanding the very loose fit of the parts and the force upon the yoke piece is very great. At the same time a long movement is obtained.

To operate the switch contacts requires a fraction of an ounce. The forces which operate on the moving plunger (which slides freely in a brass tube in oil) are over 80 lbs. at the commencement of the stroke, and are several pounds at the end. The sliding plunger itself weighs 3 pounds. There is, therefore, a margin of safety of many hundred per cent. As the car passes on, there is a breaking of the magnetic and also of the electric circuit, adding to the security. There is yet a third line of defense to the public in that the switch is actually earthed, if when the car passes on the switch fails to open: for then the plunger earths the switch. In that event the fuse would be blown, effectually protecting the public from the possibility of a stud being left alive in the roadway.

It will be seen from Fig. 3 that three cups are employed; the two outer being connected to the main and the stud respectively. The main cup is inclosed in a metal sheath (not shown) permanently connected to earth, so that it is impossible for current to reach the stud except when the yoke is down. It will be seen from Fig. 3 that when the plunger is down it earths the center cup, so that if from any accident whatever the yoke piece fails to open the switch after a car has gone past, the plunger puts the stud to earth and blows the fuse between it and the main. Either shunt or series coils may be used to connect up the switch boxes. In practice a shunt coil is preferred because the slightly increased expense is more than compensated for by the smallness of the bulk. Only one skate is employed, and this is in the center of the car. This gives much greater facility in going round curves than where two skates and two rows of studs are necessary.

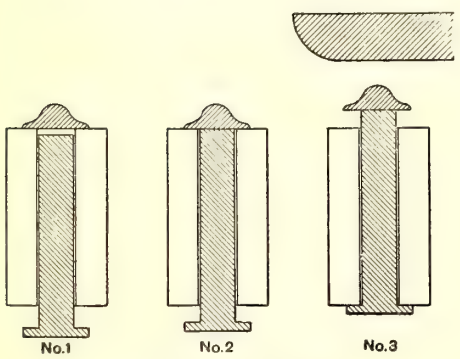

FIG. 2.—PLUNGERS

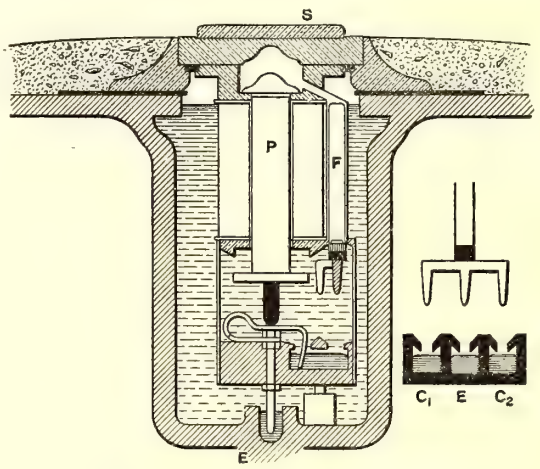

FIG. 3.—SECTION OF CONTACT BOX

New Electric Railway in Virginia

Contracts for the construction of the Norfolk & Atlantic Terminal Railroad, which is to run from Norfolk to Sewell's Point, Va., have recently been let to the Tennis Construction Company, Stephen Gerard Building, Philadelphia. The road will be operated by the overhead electric system and contracts for the material required have been awarded as follows: Hamilton Corliss Engine Company, Hamilton, Ohio, engines; E. Keeler, Williamsport, Pa., boilers; Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa., generators, motors, etc.; H. W. Johns Manufacturing Company, New York City, overhead equipment; Maryland Steel Company, Sparrows' Point, Md., steel rails.

Telephones for Street Railway Service

The advantages of a private telephone exchange for connecting the different departments or offices of large corporations are so obvious that the demand for these exchanges has greatly increased within the past few months. To meet this call the Viaduct Manufacturing Company, of Baltimore, Md., is manufacturing a full line of telephones and accessories for private exchanges, and special care has been given to the designing of telephone instruments for the use of street railway companies. These instruments operate independently of a central exchange. They are made in two patterns; one, which is shown in Fig. 1, is a desk telephone with a switch located in the base, and the other, Fig. 2, is a wall telephone, with a switch in the face of the case. By means of the switches calls are made to any of the other instruments on the system. The calls may be received with the switch on any point, but in order to talk with the new call it is necessary to place the switch upon the home stud. The use of these instruments avoids the necessity of a switchboard and attendant.

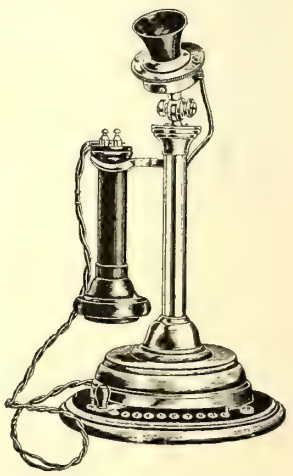

FIG. 1.—DESK TELEPHONE

This company also makes a portable telephone outfit designed for the use of the street railway conductors, who are required to report to the starter at the station from any point on the road. For using these instruments when no special provision has been made, contact is made by throwing the wire over the telephone line wire and making a ground connection, but where a metallic circuit is employed, contact is made with both limbs of the service. Where there is much telephoning to be done it is better to provide cut-outs at intervals on the trolley poles along the line, so that the plugs of the telephone instrument can be attached directly to the circuit. The portable outfit consists of a generator ringer, a re-

ceiver of hard rubber, the transmitter and two-cell dry battery. This is all inclosed in a neat case and provided with a strap for carrying. The outfit weighs only about 9 lbs.

Another specialty manufactured by the Viaduct Manufacturing Company for the use of electric railways is an alarm or signal for use in outlying districts. This instrument is fitted with a large vibrating gong, and is intended to be attached to a trolley pole. In this way the starter can signal the conductor of a passing car should he wish to communicate with him while on his trip. This signal can be used in connection with either a stationary telephone at the same pole to which the gong is attached, or else the conductors can be supplied with a portable outfit.

Storage Air Brake System

A new type of air brake has been in use for some time on the Detroit & Pontiac Railway, as mentioned elsewhere in this issue, and is giving excellent satisfaction there. It is placed on the market by the G. P. Magann Air Brake Company, of Detroit, Mich., and is illustrated in detail in the accompanying engravings. The system contains a number of novel features, one of which is that no compressing devices, either axle or motor driven, are carried on the car, but the air is compressed to the requisite pressure by means of a stationary steam driven compressor in the power station, and is then stored in reservoirs on the car for use. This, of course, reduces enormously the amount of apparatus required, and removes entirely the most complicated part of the air brake system to the station, where it can be directly under the supervision of the power house engineer. The chief claims made for this radical step are that it eliminates: first, any noise from the air-pump when the car is at rest; second, attention required to the pump and its motor, either on the road or in the car house; third, possibility of breakdown; fourth, greater amount of apparatus, and, fifth, the loss of valuable space in the car.

As in use on the Pontiac line, the air is first compressed at the power station to 225 lbs. per square inch by means of a Laidlaw-Dunn-Gordon reciprocating air pump located near the boilers and driven directly by steam pressure, and is stored in a large reservoir, from which it is piped to an adjustable coupling near the track. Each car carries two storage cylinders made of riveted sheet steel and tested under hydraulic pressure to double their working pressure. These cylinders have a capacity aggregating about 36 cu. ft. and are stored to 225 lbs. The time required for making connections, charging and breaking connections, is less than half a minute, and is done while the conductor is obliged to enter the office of the company at that point and make his usual report. The storage tanks on the car are piped through a reducing valve to a small reservoir which carries 40-lb. pressure, which is the working pressure. The usual connections are then made from this small reservoir to the jam cylinder through a 3-way controlling valve on the platform. The jam cylinder is of the differential type, air being admitted on both sides of the piston, which moves in two cylinders of different sizes. To stop the car the large-sized cylinder is exhausted, allowing the air pressure in the smaller cylinder to force the brake on. To release the brakes air is admitted to the large side forcing the brake off, making a positive release. This also allows the motorman to put on only the requisite braking pressure, any undue pressure being immediately relieved by air cushioning in the large cylinder. With 36 cu. ft. stored to an original pressure, 200 lbs., a large double truck interurban car on the Pontiac line ran six hours and twenty minutes, or a total of 96 miles, in a hilly region, and made 228 stops. When the car was run into the car house there was still enough air pressure to handle the brakes with ease, the gage showing 40 lbs.

The average reduction in pressure in the large cylinder for each stop is 0.8 lbs.

The equipment has been in constant use on the line mentioned for over nine months without requiring any repairs.

DIAGRAM OF AIR BRAKE EQUIPMENT FOR DOUBLE-TRUCK CARS

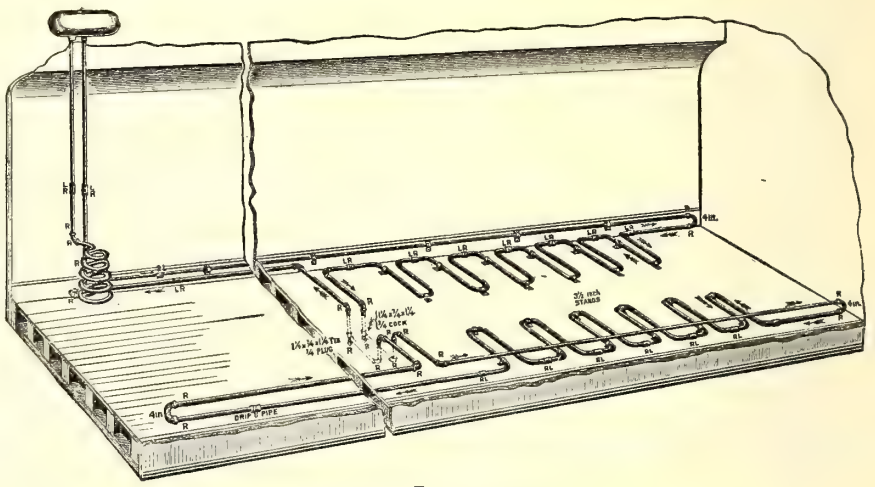
Hot Water Heaters for Electric Railways

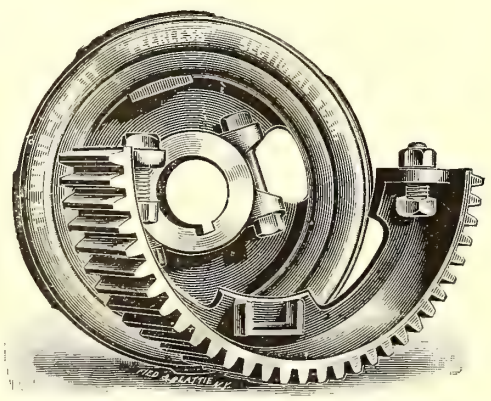
The increasing use of long double-truck cars has brought the method of car heating by hot water for electric railway cars into considerable prominence. As mentioned elsewhere in this issue, the principal interurban railways in the vicinity of Detroit are employing for car heating an improved type of the Baker hot water heater, which has been so extensively employed in steam railroads for the last thirty years. The heater is made in a variety of sizes, that employed on the Detroit suburban cars being known as the "Mighty Midget." This type embodies all the features which have given these heaters their high reputation.

The generator coil forms a complete water cage for the fire, as the latter is entirely within it. This coil is seamless and is tested by high hydraulic pressure before installing. The pipe is 1¼ ins. in diameter and has a spiral length equivalent to 22 ft. 4 ins.

The water employed is saturated with salt to prevent freezing, and its course is first through the generating coil, thence upward into the water reservoir and expansion drum above the heater. It is thence downward through the radiating pipes which are run along the sides or under the seats of the car, then back to the generating coil. Salt is employed to keep the water from freezing, but it is found this does not exercise any deleterious effect on the inside of the pipes.

HEATER





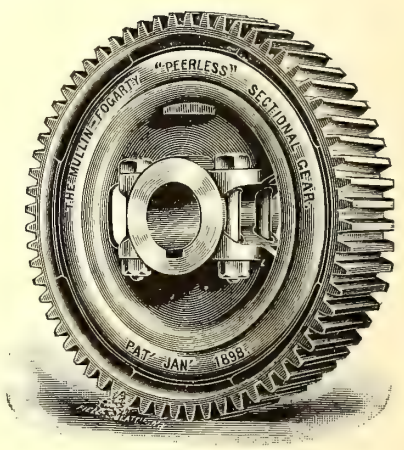


DIAGRAM OF PIPING

SECTIONAL GEAR WITH HUB AND RIM SEPARATED

SECTIONAL GEAR

Usually these heaters are placed in the front vestibule, and what little care is required by them is given by the motorman. The position of the heater on the car at this point does not take up any valuable space and serves to keep the vestibule warm. The diameter of this sized heater is 18½ ins., its height is 3½ ft., and its weight, boxed ready for shipping, is 520 lbs.

These heaters are giving splendid satisfaction in Detroit, Minneapolis, St. Paul, Milwaukee and other large cities where large cars are used, and seem adapted for electric car heating purposes, especially for long cars on interurban and suburban roads, such as exist in these cities and are becoming common in all sections of the country. These heaters are manufactured by William C. Baker, successor to the Baker Heating Company, New York.

The Electrical Installation Company, of Chicago, has been doing a large amount of construction work recently, notably in Kansas City, where it is changing the Broadway Cable line to electricity.

Sectional Gears

A new sectional gear, embodying a number of novel features, is shown in the accompanying illustrations. The invention consists of a cast-iron hub, or center-piece, to which are attached removable sections of any metal specified. These sections are interchangeable. When the hub, or center-piece, has been once keyed in place on the shaft it does not require any further attention, and when the teeth of the rim sections have become worn, these sections can be taken off and replaced by new ones in a few moments, thus making practically a new gear.

The hub piece and rim sections are beveled where they come in contact with each other in such a way as to make a perfect fit and prevent all lateral motion. To do away with the possibility of the rim revolving on the center-piece, a steel safety key is slipped in place between the rim and the hub, absolutely locking them. The advantages of an interchangeable construction of this kind will be evident to any one using gears, as it removes the necessity of taking off the entire gear as soon as a few of the teeth are worn out or broken. This construction also makes an extremely light wheel without, it is claimed, reducing the strength. One cut shows a complete gear with a solid hub, and the other, the hub and one section of the rim before being placed in position on the hub. These gears can be made of any shape and pitch with coiled discs for small sizes and with arms for larger sizes, if desired. They are manufactured by the Peerless Section Gear Company, of New York City.

The Worthington Water Tube Boiler

The Worthington boiler, which is illustrated herewith, has been used to considerable extent in electric light and other work, and has established a high reputation for compactness, accessibility and economy of fuel. The furnace extends under the entire boiler and is of proper height to permit the use of any kind of fuel. The tubes are lap-welded and each is straight. The circulation of the water, as will be seen, is upward in every tube with the exception of the two downtakes at each end of the boiler, which are not exposed to the gases. The course of the water is then, from the steam and water drum located above the tubes into which it is fed, through

the downtakes placed outside of the furnace to the mud drums at the base, thence by the tube connections into the lower series of headers, thence through the tubes over the fire through the upper series of headers, thence by the tube connections into the water and steam drum from whence it started.

As the tubes are short, their linear expansion and contraction are not perceptible and they can easily be cleaned. The headers are of steel or iron, according to the service required, and are arranged in the boiler close together, forming complete side walls. The furnace is lined with fire brick. The only other brick required, excepting in boilers of large units, consists of two foundation walls of proper depth, rising above the floor level about 12 ins.

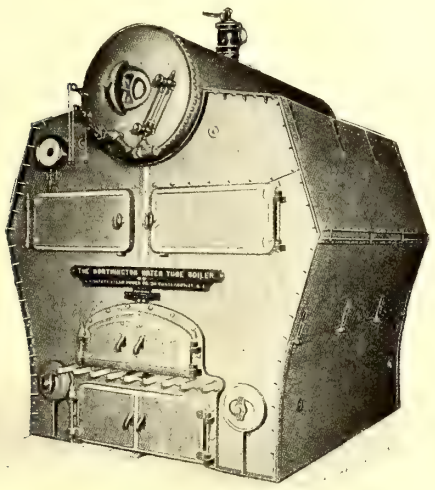
From the fire the gases rise, percolating through the tubes, which are thus exposed directly to the action of the fire, and finally make their exit at the top on either side, as is most convenient.

The vertical space between the tubes is only about ⅜ in. No baffle plates are used, and, as the gases rise perpendicularly and without any sharp turn, the draft is good. It is estimated by the manufacturers that the boiler will run to its full capacity with about ⅛-in. draft, or about one-half that required by other boilers.

Another important feature of the boiler is the quality of the steam. As will be noticed from the design of the boiler, the circulation is excellent, and when the steam from the pipes is discharged into the steam drum the distribution is along the whole length of the drum and at the surface, and not underneath the water. The delivery is therefore quiet and the steam does not take up any of the water from the drum. As it impinges against a small baffle plate in the drum on entering the latter, the water held mechanically in the steam is separated from it.

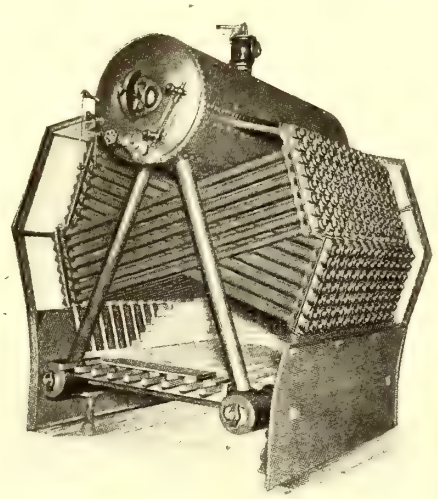
The water enters the mud drum from the ends and leaves it from near the center. At the latter point, therefore, is a dead place where the mud accumulates and where the blow-off is located.

Owing to the fact that the heat is so directly utilized, the boiler requires a less grate surface than most other makes. Economy of floor space is an important feature of this boiler. This will be seen from the statement that the 25-h.p. boiler is 9 ft. 4 ins. in length, 8 ft. 9 ins. in width and has a total height of 10 ft. The amount of saving in floor space is figured at about 50 per cent. The boiler can be fired either at the ends or on the sides. The normal condition is the end method of firing and is the one shown in the engraving. Where desired, however, the end can be closed up and the boilers fired at the side. This is usually done on large boilers, because the boiler is made of sections, and beyond a certain depth it would be impossible to reach the end of the grate surface easily.



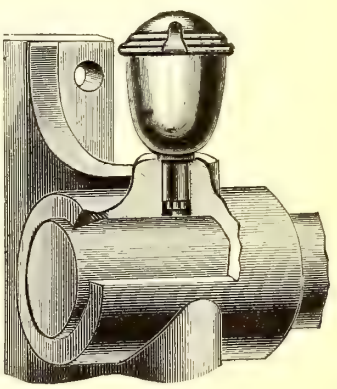
Where the boiler is fired on the side two or three of the headers are removed and the end is closed up.

The following are some figures secured from a test of boilers made in June, 1897, by Prof. D. S. Jacobus, of Stevens Institute of Technology, on boilers in the plant of the American Surety Building, New York:



Builder's rating of h.p.			142
Heating surface, in square feet			1275
Grate surface, in square feet			36.35
Ratio of heating to grate surface			35.1
Number of test	1	2	3
Date of test	June 1.	June 4.	June 7.
Length of test in hours and minutes	10-17	12-12	11-11
Total Quantities—			
Coal consumed, not deducting moisture in same, in lbs.	10,664	6,556	10.881
Wood used in starting fire, in lbs.	159	159.5	150
Coal equivalent in wood at 0.4 x weight of coal, in lbs.	10,728	6,620	10,911
Ashes, in lbs.	1,651	1,149	1,857
Net combustible, in lbs.	9,077	5,471	9,084
Water evaporated during test, in lbs.	69,785	50,484	73,438
Water evaporated during test, in lbs, per hour	6,786.4	4,138.1	6,566.9
Average Quantities—			
Pressure of steam, in lbs per sq. in above atmosphere	94.55	92.72	95.56
Temperature of feed water, in degrees F.	65.14	64.45	64.34
Temperature of boiler room in deg. F., dry bulb.	79.17	87.18	80.02
Temperature of boiler room in deg. F., wet bulb.	68.91	78.50	66.59
Draught, in inches of water, in flue leading to chimney	1.057	0.814	1.124
Draught, in inches of water, in connection at top of boiler leading to flue	0.548	0.212	0.461
Percentage of ash in coal	15.39	17.36	16.97
Percentage of moisture in coal	2.06	1.80	2.00
Temperature of flue gases, in degrees F	504.4	440.4	524.9
Calculated Quantities—			
Factor of evaporation	1.191	1.191	1.192
Pounds of water evaporated per lb. of coal, not deducting moisture in coal (actual)	6.50	7.63	6.71
Pounds of water evaporated per lb. of coal, not deducting moisture in coal (from and at 212 F).	7.75	9.08	8.00
Evaporation in lbs. per lb. of combustible, not deducting moisture in coal (actual)	7.69	9.23	8.08
Evaporation in lbs. per lb. of combustible, not deducting moisture in coal (from and at 212 F).	9.16	10.99	9.63
Evaporation in lbs. per lb. of combustible from and at 212 F., deducting the moisture contained in the coal	9.38	11.23	9.87
Coal burned per sq. foot of grate surface per hour, in lbs.	28.7	14.9	26.9
Water evaporated per sq. ft heating surface per hour, in lbs.	5.32	3.25	5.15
Horse-power of boiler.—One h.p. 34½ lbs. of water evaporated from and at 212 F., per hour	234.3	142.9	226.9

Lubricating Compounds and Cups



A lubricating compound, which is claimed to give absolute satisfaction under all conditions of temperature, wear, etc., is made by the Albany Lubricating Compound & Cup Company, of which Adam Cook's Sons, of New York, are the proprietors. This compound is known as Albany grease, and when it is used the manufacturers guarantee that it will absolutely prevent the burning out of armatures and overheating of bearings.

EXTERIOR OF BOILER

BOILER WITH SIDE REMOVED

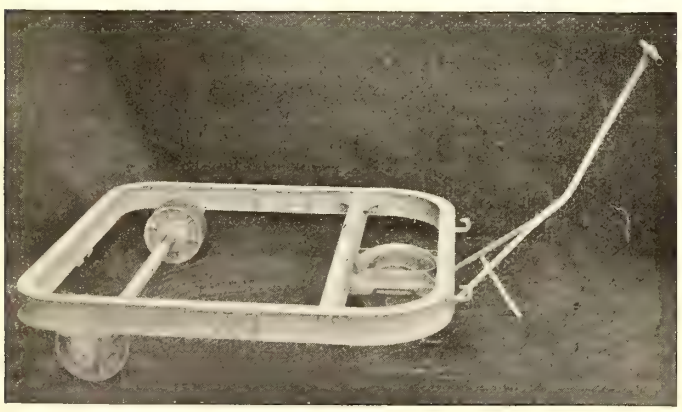
LUBRICATING CUP

The Albany compound is usually made in four different degrees of hardness, figures being used to denote the different grades; No. 0 is very soft, being for use in extreme cold weather and on exposed journals; No. 1 is harder than No. 0, and is to be used on ordinary journals in cold weather, or on very cool or slow running journals; No. 2 is still harder and is a grade ordinarily used in moderate and warm weather; No. 3 is adapted to the use of all stationary, marine and tugboat engines, also shafting in warm weather. An extra grade, known as No. X, is also made. This is very hard, and it is stated will lubricate journals when no oil or other lubricant will work.

A special lubricating cup has been designed by Adam Cook's Sons, and they advise its use with their Albany grease, to secure the best results. The cup is shown herewith. As will be seen, the manner of attaching it is very simple, and it can be done by any mechanic. The Albany cups require the minimum of attention and very seldom get out of order. When filled with the lubricating composition they will run from one to four months, according to the power and velocity of the shafting, without refilling. They thus effect a great saving of labor, as well as in the cost of lubrication. With the use of Albany grease and these cups, no drip pans are required.

Combined Baggage and Passenger Car

The two great fertile valleys of Frederick and Middletown, in Maryland, have recently been connected by a street railway running through a gap in the mountains. The termini are respectively the cities of Frederick and Middletown. It is a matter of some interest to know that this electric railway takes nearly the same



COMBINATION BAGGAGE AND PASSENGER CAR

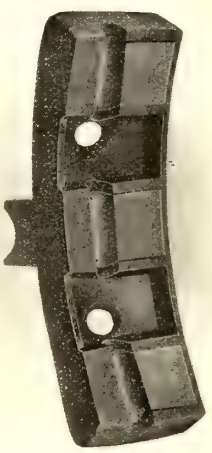
line as the Great National Road of the early part of the century. Communication until the advent of the railway had been difficult between the two valleys, owing to high tolls and the steepness of the grades. The successful operation of the road is developing a baggage and express business in addition to the passenger traffic. The car illustrated shows the method which the road has adopted to carry on this business in an economical manner. The cars of the road are mounted on No. 21 E trucks, and the same truck is employed for the combination express and baggage car, which also has a passenger compartment. There is considerable advantage in combining the service, because it does not interrupt the regularity of the trips, as is the case where the car is exclusively devoted to freight and carries no passengers.

The car is 18 ft. long over end panels and 7 ft. 6 ins. wide at belt rails. There are two G. E. 51 motors for propulsion. The platforms are 4 ft. long and have vestibules with folding doors, and are plated with sheet steel. They are also provided with angle iron bumpers. The trim of the car throughout is of solid bronze. The passengers' compartment is 8 ft. 8 ins. long, and the remaining portion of the body is finished in hardwood with folding seats, making a baggage, express and smoking compartment. There is a sliding door in the partition between them. The oak side sills are of unusual depth and are plated to provide the necessary strength. Brill sand boxes and gongs are provided. Taken altogether, the car is a very neat and complete example of its type as adapted for use on interurban roads.

Hand Trucks for Buenos Ayres

In the STREET RAILWAY JOURNAL for November, 1898, was described the method by which meat is handled in the city of Buenos Ayres between the slaughter houses and the markets. Reference was made in the article to the trucks upon which the meat boxes

HAND TRUCK



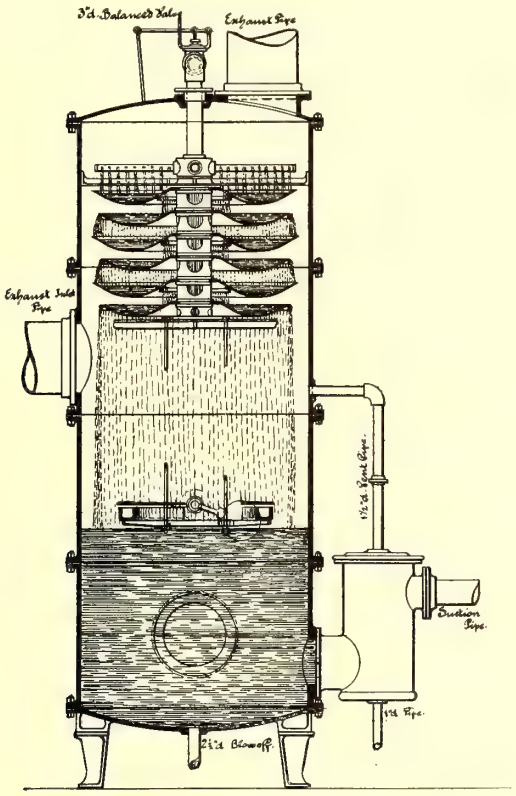
were handled on arrival at destination. The accompanying illustration shows one of these trucks. They are mounted practically upon three wheels, although the forward wheel is doubled, to facilitate turning. This forward wheel is set in a turn-table carried in ball-bearings, and the whole truck can be turned in its own length. While it is intended that these trucks should be moved by hand, a large portion of the work done with them is performed by means of mules, and the trucks themselves are arranged so they can be hauled in trains.

The handle of one truck is made of sufficient length to drop into the hooks at the rear end of the truck in front of it. The handles of the forward truck can be turned up against the meat box, or can be unshipped and the team attached to the two hooks seen in front of the trucks. The construction is exceedingly simple, and at the same time of the greatest strength. Hyatt's roller-bearings for each journal reduces the friction to a minimum. This is a small truck that might be used to advantage in repair shops, depots and other places where heavy weights are to be moved and when the roads do not have overhead trolleys for the purpose. The trucks illustrated were made for 6000 lbs. capacity, but they can be built for any desired load from 1000 lbs. up.

Remedy for Flat Wheels

The annoyance to passengers from "flat" wheels and the expense to the street railway company of renewing these wheels has made this problem of preventing "skidded" wheels one of the most serious that the manager has to meet. Various methods have been suggested as to the best way of dealing with the problem, one of the latest being the use of a brake shoe containing emery inserts. This shoe is designed to be substituted for the ordinary brake shoe on a wheel that has become flattened, and in this way to gradually true up the wheel without removing it or the car from service.

This shoe has been introduced by the Wheel Truing Brake Shoe Company, of Detroit, Mich., and is in every way similar to the regular brake shoe with the exception that in its face it contains pockets or compartments, every alternate one of which is filled with an emery mixture baked hard like the section of an emery wheel. When the wheel becomes flattened the regular brake shoe is removed and the wheel truing brake shoe is put on in its place. The car is then run as usual, and every time the motorman applies the brake, for the purpose of checking the speed of the car, the wheel is ground down a little and brought back to the proper shape. The shoe, of course, grinds only when the brake is applied, so that usually it requires a number of trips to true up the wheel and then the old shoes are replaced. It will be seen that in this way the new brake shoe acts upon the same principle as an emery wheel, with the exception that the emery is held stationary and the wheel revolves against it. The face of the shoe is a part of a true circle, and therefore the shape imparted to the wheel will be perfectly true. The time required to take off the old shoes and put on the wheel truing brake shoe is very short compared with the loss of time incident to running the car into the barn and jacking up for the purpose of grinding the wheels.



SHOE FOR TRUING FLAT WHEELS

These shoes have passed the experimental stage and are now in use on a number of roads. The Rapid Railway, running between Detroit and Mt. Clemens, Mich., was the first road to equip its cars with them, and it is stated that this company has not been obliged to remove any wheels, for the purpose of truing them up, since the time the new shoes have been in operation. The invention is patented in America and in all European countries, the later patents being the exclusive property of J. M. Griffin, the president of the company which is handling the shoe in the United States.

Open and Closed Feed Water Heaters and Purifiers

Steam users designate the two leading types of feed water heaters as open and closed. In the former the water is divided by means of open pans, so that the exhaust steam comes in direct contact with the agitated water. In the closed type the cold water is directed through a nest of pipes, and is heated by the surrounding steam. An open type of heater is shown in the accompanying

illustrations, Figs. 1 and 2. In this particular type the shells, as well as the interior parts, are made from cast iron, it being found that this metal is less liable to corrosion than steel or rolled iron. As will be noted, the interior construction consists of a series of round settling pans, mounted one above another on a central hollow shaft, but loosely, so that they can be readily turned and every part be brought before a side door in the shell, when they are easily cleaned or inspected. The water is admitted at the top through perforated branching pipes of brass, by which means the water is evenly sprayed over the whole surface of the upper pan, which is perforated, and from which the water flows in small streams to the pan below, then over the edges of the succeeding pans until it is accumulated at the bottom of the heater. Exhaust steam is admitted through the sides of the heater, below the pans, and ascends along the outer edge of the pans and through the perforated hollow shaft, so that it passes over the surface of each pan, imparting its heat to the finely subdivided water, causing rapid

SECTION OF HEATER

condensation, with little or no back pressure. In its passage all impurities are deposited in the pans or at the bottom of the heater.

A horse-shoe trough within the shell at the normal water level serves to skim off and discharge the oil or other floating impurities, while a sensitive float, consisting of a copper ball, operates a valve in the supply pipe, at the top, and thus regulates the supply of water. A small auxiliary cylinder, known as an oil separator, is attached to the side of the shell, and is connected by a pipe to the water in the base of the shell, but a little above the bottom. The suction pipe from the feed pump enters this auxiliary cylinder a little below the surface of the water, while a second pipe, or by-pass, connects the top of the cylinder with the steam space in the heater, and so designed that should the water, from any cause, fall to a level with the suction pipe, it would draw steam instead of water, or the oil that might possibly have gained entrance to the cylinder. Blowoff pipes for removing the sediment are provided at the bottom at both the main shell and the auxiliary cylinder. A water gage and thermometer complete the essential parts of the heater. The heaters as above described are known as the Pittsburgh feed-water heaters and purifiers, and for which James Bonar & Co. are general sales agents.

The same concern handles a closed type of heaters that are manufactured in various shapes, both with curved and straight pipes, which united different chambers, and providing large heating surface.

The open heaters are manufactured in sizes from 50 h.p. to 6000 h.p. Some of the shells, as shown by Fig. 1, are from 18 ft. to 20 ft. in height and 5 ft. to 6 ft. in diameter. The heaters of different types are manufactured in Pittsburgh under the direction of J. E. Schlieper, by whom they were designed and patented.

The "Sterling" Specialties

The beautiful white enameled dial of the Sterling Supply & Manufacturing Company is coming to be seen more and more often on the cars of American street railways, small as well as large, though hitherto a favorite among the larger companies chiefly. Its exclusive use by the Metropolitan Street Railway Company, of New York, is, of course, almost in itself a guarantee of its excellence and satisfactory qualities, since it is well known that every possible "leak" is avoided on the Metropolitan system, and no leak is so important as that of earnings. The Sterling trip and totalizing alarm registers are made with either the plain white numeral disc referred to, or the dial indicator, as may be preferred, and are arranged for either cord or rod connection, as desired. All of the auxiliary equipment devices are of the finest quality and most carefully made.

Nearly every one who rides on the Broadway cars in New York City wonders at the power and delicate adjustment of the brakes in use thereon, by means of which a car may be run in a crowded street at considerable speed, almost to the point of touching a wagon or another car in front, and yet may be instantly brought to a complete stop by a slight movement of the gripman's hand. The brake which accomplishes this result is the invention of Thomas Millen, master mechanic of the Metropolitan Street Railway Company, and is made by the Sterling Company. It is a simple hand brake with one essential peculiarity, namely, that the usual movement of the brake rod is multiplied in power through a gear and pinion working in the ratio of 5 to 2. On the gear axle is a double

GROUP OF HEATERS

sprocket wheel, which operates the brake levers by means of a chain. Another feature of the entire brake apparatus is that the brake shoes are run very close to the wheel, so that a slight motion only is necessary to bring them to full bearing, and the wear on the brake shoe is taken up in the chains connecting with the brake rod. There is a material saving also in the wear of chains as compared with the old-fashioned brakes. With the sprocket wheel used a chain usually wears several years.

Another well-known device made by the company is a street car fender also in use in New York and other cities. This is a track fender, not a dashboard fender.

The Sterling Company has recently enlarged that portion of its plant devoted to the manufacture of insulating material and commutator bars, and large quantities are being turned out to meet a greatly increased demand. The insulation is a special compound molded while in a plastic state under hydraulic pressure. It is hard, tough and impervious to weather, and has high insulating qualities.

In addition to these more important specialties, the Sterling Company also manufactures a large line of street railway supplies of various kinds, including the Sterling sand box, conductors' badges, the Sterling counter for counting reciprocating or rotary movements, including revolutions of wheel axles, machinery, etc., a wire measuring machine and a winding machine for recording revolutions of spindles and armature bobbins. With so large a number and variety of specialties, it goes without saying that the Sterling Company is of great use to street railway purchasers.

The Bloomfield (Mich.) & Orchard Lake Electric Railroad Company has been incorporated with a capital stock of $50,000. George L. Hendrie is the principal stockholder.

The Lord Baltimore Maximum Traction Truck

The design of this truck conforms to that of the well-known Lord Baltimore single and center bearing trucks. The pedestals are of steel and form part of the side frames; they are provided with housings to receive graduated coil springs, which rest on the axle boxes and carry entire weight, thoroughly cushioning all. The car body and load ride upon four half elliptic springs, two to each truck and suspended from the below the side frames by links and connected by posts to the truck bolster, the posts being held in place between and guided by the bars forming part of side frames and connecting the pedestals. They are of bolster construction, to which pivotal centers are fastened, the pivotal centers being located at or near the centers of driving axles; the weight of the entire structure is so proportioned that 66 per cent rests upon the driving wheels, and is applied to the wheels through bolsters and distributed upon centers of bolsters and self-oiling roller side-bearings revolving upon steel thimbles. These roller side-bearings, upon which car body chafe plates bear, are placed directly above centers of half elliptic body springs. The axle boxes are of most approved dust and oil tight pattern and provided with either felt or waste feed, as may be desired.

The driver and cross frames are bolted directly to the main pedestals and of such form that they will never be outside of track line in curving; the only function they perform is to carry bars supporting the motors upon outer ends, the motors being placed outside of drivers.

These end cross frames form stiff end ties for side frames, which are also securely braced diagonally between the wheels. The frames, taken as a whole, are as securely built as the best locomotive trucks and have all the advantages of stiffness and stability claimed for center-bearing trucks of the most approved design.

The brakes are applied between wheels and so constructed with proportioned levers that 70 per cent of the braking power is applied to the drivers; they are operated by levers acting from the pivotal points of trucks, avoiding the use of objectionable quadrants in applying brakes upon curves; all the working parts of the brake mechanism have large bearings provided with oil holes, work upon steel thimbles, are placed at center lines of trucks and not liable to receive mud or dust thrown up by the wheels. They are extremely powerful, and the braking power is equalized between the trucks by interposing springs in such manner that it will be divided equally between the trucks, and each wheel will receive its proper proportion of the braking power.

These trucks are thoroughly and carefully built in every particular, and special attention has been given to preventing shearing strains upon the bolts, and all parts are of steel and malleable iron, no cast iron being used except for wheels and brake shoes.

The trucks are manufactured by the Baltimore Car Wheel Company, of Baltimore, Md.

Transformer Design and Operation

Under the title, "Transformer Design and Operation," the General Electric Company issues a pamphlet from two important papers on the subject of electrical transformers. One is written from the standpoint of the central station manager by W. F. White, general manager of the Omaha (Neb.) Electric Light, Heat & Power Company; the other, by Prof. Winder Elwell Goldsborough, M. D., deals intimately with the question of transformer economy. The first paper, which was read before the American Institute of Electrical Engineers, is the record of long personal experience with the operation of transformers under actual commercial conditions, showing the relation of the many losses incident to the use of many small transformers to the earing capacity of the plant, and the very tangible economies realized as the result of the substitution of a few high efficiency transformers of large capacity. Mr. White gives examples of these economics reduced to dollars and cents. In his station a saving of $6,000 per annum in the cost of coal alone was realized as the result of the practical application of lessons drawn from his extended observation and experience.

Prof. Goldsborough's paper was read before the National Electric Light Association, and treats of the inherent economy of transformers of various design and construction. It contains many able arguments in favor of the use of high-grade transformers, and emphasizes the necessity of frequent tests as the only means of detecting leaks, losses and the general depreciation of transformers. Prof. Goldsborough gives examples of manufacturers' claims belied by careful test, but instances other cases in which guarantees have been exceeded, and urges upon station managers the wisdom of keeping as vigilant a watch on the efficiency of their transforming apparatus as upon the items of operating expense and maintenance if economical results are to be obtained.

To these papers the General Electric Company has added several maps showing graphically the significance of the substitution of a few large transformers for numerous small ones. The pamphlet is, as usual, well printed and illustrated, and should find a prominent place in the literature of every alternating current station and every educational institution. It will be sent free by the General Electric Company.

Personals

MR. JOHN B. HICKS has resigned his position as manager of the railway department for Pratt & Lambert.

MR. W. W. RUTHERFORD has been elected chairman of the Liverpool Tramways Committee and Alderman F. Smith has been appointed deputy chairman.

MR. GEORGE J. JACKSON, of New York, is spending the winter in London, looking after the interests of the recently incorporated National Conduit & Cable Company, Ltd.

MR. CHARLES H. KIRKLAND has made arrangements for handling in New York the supplies of the Bibber-White Company and the Crefield Electrical Works, both of Boston. Mr. Kirkland has been for some time in the sales department of the C. & C. Electric Company.

MESSRS. E. E. SOLDANA, N. T. HARRINGTON AND H. H. WATSON, of the E. P. Allis Company, have returned to America from Europe. Messrs. Soldana and Harrington have just completed the erection of two 500-h.p. engines at Madrid and three at Barcelona, Spain.

HON. GARDNER C. SIMS, who served during the war with Spain as one of the chief engineering officers on the "Vulcan," has returned home, to Providence. The "Vulcan," as is well known, was the repair ship for the fleet off Santiago, and as such rendered

MR. HENRY G. ISSERTEL, formerly manager of the Boston office of the Walker Company, has accepted the position of manager of the New York office of the Anchor Electric Company, which makes a specialty of high-grade switches. Mr. Issertel's headquarters will be at 26 Cortlandt Street.

MR. O. VON GOBEN, MR. FREDERICK TISCHENDORFER, MR. B. WINTER-GUNTHER and MR. PETERSEN, all connected with the Elektricitäts Aktien Gesellschaft vorm. Schuckert & Co., were in New York last month inspecting a number of electric railway plants, including the third-rail system in use on the Marine Railway at Coney Island. Mr. Tischendörfer will remain in this country about a month longer. The other three gentlemen returned to Nuremburg Dec. 10.

MR. A. BAKER, manager of the Nottingham Corporation Tramways, has been appointed to the post of "Chief Officer of Tramways" of London by the London County Council, and his appointment was ratified Dec. 13. Mr. Baker has shown conspicuous ability in the discharge of his duties at Nottingham, and much satisfaction is expressed at his acceptance of the post in London. It has been decided to call the London tramways "The London County Council Tramways," although only the initials, "L. C. C.," will be painted on the cars.

PROF. SIDNEY H. SHORT, of Cleveland, sailed for Liverpool on the Majestic, Dec. 13, for an extended tour in England and the Continent. In the course of his travels he will visit London, Paris, Frankfort and Berlin, besides many other places of interest. This is almost the first real vacation which Prof. Short has had for many years, and his intention is to devote his time chiefly to recreation, although he has already been invited to address a number of scientific societies in England, France and Germany on the subjects, particularly, of application of electricity to heavy railroading, and of high speed traction, on which subjects he is recognized as an authority of high standing. Prof. Short is accompanied by Mrs. Short, and they expect to return to America about the middle of April.

MR. JOHN YOUNG, manager of the Glasgow Corporation Tramways, has recently declined the office of Chief of the Tramways Department in London. Mr. Young's recent work in Glas-

gow is known throughout the tramway field, and his remarkable success in bringing the Glasgow Municipal Tramway service to its present state of efficiency has placed his name among the foremost tramway managers of the world. Mr. Young was born in 1845 at Fulwood, Renfrewshire. He received his early education at the Paisley Grammar School, and expected to take up the duties of a professional life. His love of the country led him to devote himself to the practical study of agriculture, and for a time he was in charge of his father's farms. It was from this position that in 1895 he was appointed Superintendent for Cleansing in Glasgow. Shortly after that time he became manager of the tramway systems of Glasgow, and under his guidance all the various departments of the tramways were thoroughly organized and equipped.

MR. FRANKLIN E. HUNTRESS has been re-elected for the third time from the Seventh Middlesex District to the Massachusetts House of Representatives. This is the first instance in the history of the city that a candidate has ever received three terms from his ward. Mr. Huntress was successful against the combined efforts of the local machines, and, though there was a large number of candidates, he carried his own ward and precincts over all others. He has served for two years on the committee on manufactures, which has supervision over the gas and electric lighting interests of the State. Mr. Huntress is a Republican, and though a candidate a number of times, he has never been defeated. He is a member of the local Republican organization, the Massachusetts Republican Club, the Middlesex Club, the University Club of Boston, and several fraternal organizations. He was graduated from Harvard University in the class of '89. In business he has been equally successful, and successfully introduced the Neal electric headlight, which has been adopted by the West End Street Railway, of Boston; the Brooklyn Heights Railroad, of Brooklyn, N. Y.; Metropolitan Street Railway, of New York City, and is in use on hundreds of roads all over the United States.

Obituary

MR. WM. E. HALE, treasurer of the Toledo Traction Company, of Toledo, Ohio, and also a prominent capitalist, died on Nov. 16, after a short illness. Mr. Hale made his home in Chicago, where he was connected with a number of large enterprises, and he was also a heavy stockholder in the Toledo Traction Company.

MR. FREDERICK CULVER WHITMORE, of the railway engineering department of the General Electric Company, died, at the early age of twenty-six years, of typhoid fever, at his home, in Hartford, Conn., on Dec. 7. Mr. Whitmore began his career with the Thomson-Houston Company, on the "students course," at the Lynn factory, from which he was advanced to the power and mining department, where he was engaged chiefly in design. In 1894 he was transferred to the Scranton, Pa., office of the General Electric Company, where he was general consulting engineer in power and mining work till 1898, at which time he returned to the home office, in Schenectady. His work at Schenectady was wholly with the railway engineering department, in which at the time of his death he was filling with conspicuous success an important post in connection with the design of special railway apparatus. Mr. Whitmore was a man of uncommon gifts, who possessed unlimited energy and enthusiasm in his work. He had, besides, a manly and straightforward character and numerous qualities of personal charm, which won him friends and gained him universal esteem.

AMONG THE MANUFACTURERS

W. C. NAGEL & CO. has been organized, with headquarters at Toledo, Ohio, for the purpose of conducting a general business in electrical machinery, supplies and construction.

THE BRITISH THOMSON-HOUSTON COMPANY has received the contract for the supply of six motor cars for the Liverpool Tramways at £554 9s. 6d. each, and sixteen trail cars with extra brakes at £587 4s. 6d. each.

THE NATIONAL INDIA RUBBER COMPANY, of Bristol, R. I., has recently published a catalogue and price list of its rubber-covered wires and cables, giving full details of all the sizes and characters of wire manufactured by them.

MESSRS. R. W. BLACKWELL & COMPANY, of Liverpool, have been granted the contract for the overhead construction for the Liverpool Tramways along the Aigharth Road, a distance of 2 miles. The contract price was £1,780 12s. 1d.

THE WEBER RAILWAY JOINT MANUFACTURING COMPANY, of New York City, has moved from the Cotton Exchange Building to the Empire Building, 71 Broadway, rooms 1813-1816, where it will be glad to receive inquiries and give information regarding the Weber joint.

THE MURRAY IRON WORKS COMPANY, of Burlington, Iowa, reports that the Sioux Corliss engine at the Omaha Exposition was awarded the gold medal over its competitors. This engine was in continuous operation, twenty-four hours per day, during the greater part of the exposition, furnishing all of the power used on the grounds.

THE WESTERN ELECTRICAL SUPPLY COMPANY, of St. Louis, Mo., has published a handsome and complete catalogue of its electric railway supplies, entitled Catalogue No. 16. This pamphlet seems to be a regular cyclopædia of all overhead parts, track tools and other apparatus required in operating electric railways, and is well illlustrated.

THE STANDARD RAILROAD SIGNAL COMPANY has moved its works from Arlington, N. J., to Troy, N. Y., where it has erected a new and much more extensive plant. Henry Burden, 2d, of New York, has been elected vice-president, and Eugene Seitz, of Troy, N. Y., treasurer, of this company, to fill vacancies caused by the resignation of Henry Johnson.

THE CONTINENTAL CONSTRUCTION COMPANY, Wentworth Building, Boston, reports some good contracts in hand for new electric roads. This company embraces in its management and directory some of the most solid and influential men in New England, and its capital is reported as sufficient to enable it to carry out any contracts the company may make. The company's principal business is the construction and equipping of electric railways complete.

THE PENNSYLVANIA ELECTRIC COMPANY, of Marietta, Pa., was granted the highest award at the Omaha Trans-Mississippi and International Exposition for telephone apparatus. The company did not make any special effort to secure the award, merely sending a line of samples to the exposition, in charge of its local agent. The Pennsylvania Electric Company is now at work on an order for 2000 telephones for the Independent Telephone Company, of Lancaster County.

THE WESTINGHOUSE COMPANIES were awarded the contract for the electrical equipment of the Third Avenue Railroad Company last month upon the lines laid down in the STREET RAILWAY JOURNAL for December. This is probably the largest contract for electric railway equipments which has ever been given to any one company or set of interests, and means, it is understood, that Westinghouse apparatus will be used throughout in the power station, rolling stock and elsewhere on the line.

THE WHITNEY CAR WHEEL WORKS, of Philadelphia, announce that they have resumed the manufacture of chilled wheels at 901 Montgomery Avenue. Having their old patterns and chills, as well as the drawings and records of all former orders for the last fifty-two years, they will be prepared to duplicate shipments made heretofore, as well as to meet new requirements. The firm is composed of James S. Whitney, manager; Asa W. Whitney, superintendent, and H. F. Hannis, treasurer.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., is furnishing the steel work for the new electric power station of the Boston & Maine Railroad Company, at Portsmouth, N. H. The building is 118 ft. wide and 64 ft. long, divided into two rooms, one for the boilers and the other for the engines and electric generators. The side walls are of brick and the roof construction is fireproof. The trusses are of steel, and they support steel beams for the purlins, on which is to be placed a concrete roof.

THE PHOSPHOR-BRONZE SMELTING COMPANY, Limited, of Philadelphia, is sending out a postal card to all its customers reading as follows: "Owing to the high prices of copper, tin, etc., we hereby withdraw all quotations on phosphor-bronze, delta metal and other alloys in manufactured goods, ingots and castings. We shall be pleased to quote prices on detailed specification for prompt orders, or to receive any orders, which will be filled at such prices as are warranted by existing conditions."

THE LOMBARD WATER WHEEL GOVERNOR COMPANY, of Boston, Mass., reports that the demand for its gov-

ernors is constantly on the increase. During the last month the company received orders for upward of twenty governors to regulate forty-one water wheels, which will develop 15,750 h.p. More than half of this machinery will be used in electric stations—principally in power transmission plants—and electric railway stations, the balance being in textile and other manufacturing plants driven by water power.

THE ELECTRIC RAILWAY & MANUFACTURERS' SUPPLY COMPANY is the title of a new firm organized in the last few months at San Francisco by Allen St. J. Bowie and S. H. Taylor. The company is agent for the Ohio Brass Company, Eureka Tempered Copper Company, Solar Carbon & Manufacturing Company, Vulcanized Fibre Company, Positive Lock Washer Company, A. O. Schoonmaker, and several other prominent Eastern manufacturers, and it is its purpose to extend its lines in the electric railway field.

THE WESTINGHOUSE MACHINE COMPANY, of Pittsburgh, Pa., is sending out quite an elaborate catalogue describing the Westinghouse compound engine. The catalogue contains handsome half-tone engravings and a large amount of information of value to steam users. The manufacturers of the Westinghouse compound engine claim that, running non-condensing, it will deliver a horse power at the shaft for a smaller expenditure of steam than any other non-condensing engine of any type whatever running under similar conditions.

THE DETROIT AUTOMATIC SWITCH COMPANY, Limited, is just introducing a new device by which a motorman can turn a switch which he is approaching without leaving the platform. The device consists in inserting in the trolley wire a short insulated section, and the motorman can operate the switch by passing this with the current on. If he does not care to move the switch, he shuts his current off and drifts past the insulated section. This device has been in use for some time at the corner of Fourteenth and Warren Avenues, Detroit, Mich.

THE Q & C COMPANY, of Chicago and New York, is sending to the trade a very handsome catalogue descriptive of the Q & C valveless pneumatic tools for riveting, chipping, caulking, cutting stray bolts, chipping iron and steel castings, stone cutting, carving, lettering, etc. The Q & C Company has recently purchased the entire business of the Ridgely & Johnson Tool Company, of Springfield, Ill., and has added a pneumatic tool department to its already well-known list of special machinery and railway appliances. Pneumatic tools are now coming into quite extensive use, and the full line carried by the Q & C Company will undoubtedly create a large demand for this class of implements.

THE WATSON-STILLMAN COMPANY, of New York City, has made arrangements for issuing from time to time special or group catalogues containing a list and descriptions of hydraulic tools best adapted for some one particular use. It has recently issued its catalogue No. 50, which illustrates tools designed for steam railroad work, and it intends to publish within a short time catalogue No. 52, which will contain tools used by street railways. Catalogue No. 51 is just being sent out, and it is shown as the "Illustrated Index of Hydraulic Tools." This index is intended to show in a medium-sized book, the large variety of tools which this concern manufactures. Each cut shown represents from one to about twenty sizes of tools, and the illustrations are intended more as suggestions than anything else. Full and complete descriptions of any one of these tools or of any class of tools will be sent upon application.

THE B. F. STURTEVANT COMPANY, of Boston, Mass., has just issued a second edition of its very suggestive pamphlet, Bulletin E, entitled "Draft Without a Chimney." The pamphlet will be sent on application. This company has also just issued its Bulletin G, which contains a description of the Sturtevant generating sets with automatic horizontal and upright engines. The generating set with horizontal center crank engine and four-pole generator manufactured by the Sturtevant Company is described elsewhere in this issue, but these sets are also made with horizontal center crank engines with six-pole generators, double upright engines with four-pole generators, single upright engines with four-pole generators, single upright engines with eight-pole generators and horizontal center crank engines with four-pole (marine type) generators. All of these sets have been very carefully designed, in order to secure the maximum amount of efficiency with the minimum amount of weight and size.

THE SAFETY THIRD-RAIL ELECTRIC COMPANY, of New York, has published from time to time very interesting and attractive printed matter describing the safety third-rail electric system, better known as the Murphy system. The latest pamphlet to be issued by this company is unusually artistic typographically, and, in addition, contains a great deal of information which will be eagerly read by all engineers, or others, interested in the development of an electric railway system to take the place of the overhead trolley in large cities on suburban and interurban railways and on steam railroads. The pamphlet just issued first describes and illustrates the principal third-rail, conduit and surface contact systems on the market, and points out some of their disadvantages. The safety third-rail system is then described, and the principal claims made for it are given in such a way as to show how the Murphy system overcomes the objectionable features in other systems.

THE HARRISON SAFETY BOILER WORKS, of Philadelphia, Pa., reports a very large number of recent sales of Cochrane separators. Among these may be mentioned: Standard Oil Company, Whiting, Ind., 6-in. oil-ammonia; De La Vergne Refrigerating Machine Company, New York, two 5-in. oil-ammonia; Buckeye Engine Company, Salem, Ohio, 5-in. vert.; Bailey Estate, Boston, one 3-in. and one 4-in. horz.; Montgomery, Ward & Co., Chicago, one each, 12-in., 7-in. and 4-in. horz.; Parke & Lacy Company, San Francisco, Cal., one each, 3½-in. and 5-in. horz., and one 5-in. vert.; Theo. A. Koch Company, Chicago, two 2-in. and one 6-in. horz.; Brown Bldg., St. Louis, Mo., three 4½-in. and one 3-in. horz.; Washington Coal & Coke Company, Star Junction, Pa., two 6-in. horz.; Fred. W. Wolf Company, Chicago, 4½-in. horz.; Jung Brewing Company, Cincinnati, Ohio, one each, 5-in. and 6-in. oil-ammonia; Buffalo (N. Y.), Bellevue & Lancaster R. R., 8-in. horz.; Cleveland, Cincinnati, Chicago & St. Louis R. R. Company, Urbana, Ill., one 5-in. and two 3-in. vert.; So. Covington & Cincinnati Street Railway Company, Newport, Ky., 4-in. horz.; Edison Electric Illuminating Company, Brockton, Mass., two 6-in. horz. A few of the recent sales of Cochrane feed-water heaters and purifiers are as follows: Raritan Copper Works, Perth Amboy, N. J., 1000 h.p.; Montgomery, Ward & Company, Chicago, 1000 h.p.; Chicago & Great Western Railroad Company, Oelwein, Iowa, 500 h.p.; Boston Packing & Provision Company, Cambridge, Mass., 200 h.p.; St. Clair (Pa.) Coal Company, 1500 h.p.; U. S. Glue Company, Carrollville, Wis., 1500 h.p.; Armour Elevator "D," Chicago, 1200 h.p.; Rush Run Coal & Coke Company, Rush Run, W. Va., 500 h.p.; Isaac Braithwaite & Son, Kendal, England, 100 h.p.; Phœnix Iron Company, Phœnixville, Pa., 2000 h.p.; Diamond Ice Company, Wilmington, Del., 200 h.p.; C. W. Boynton, Chicago, 100 h.p.; O. S. Kemmerer, Nazareth , Pa., 50 h.p. (special).

New Publications

Tourists' Guide to New Orleans. Published by the New Orleans City & Lake Railroad Company. 14 pages.

This is a neat little folder containing a map of all the street car routes in New Orleans and directions for reaching all the principal points of interest.

Graphite. Vol. 1, No. 1. December, 1898. Published by the Joseph Dixon Crucible Company, of Jersey City, N. J. 4 pages.

This is a periodical which will be issued from time to time by the Joseph Dixon Crucible Company, and will be sent to all users of graphite or others interested. Graphite now enters very extensively into most of the arts, sciences and trades, and is, in fact, employed in some form by every civilized nation in the world.

President's Address Before the American Society of Mechanical Engineers. 15 pages. Published by the American Society of Mechanical Engineers.

This is a copy of the address delivered by President Charles Wallace Hunt before the above-mentioned society. In his address Mr. Hunt carefully reviewed the latest engineering practice in America and abroad, and spoke of the duties, pleasures and usefulness of the engineer of to-day.

Report of the Sixteenth Annual Meeting of the Street Railway Association of the State of New York. Published by the New York State Street Railway Association. 144 pages.

This is the printed proceedings of the sixteenth annual meeting of this association, which was held at the Manhattan Hotel, Brooklyn, N. Y., Sept. 13-14, 1898. The report is very complete, giving all the papers read, all the discussions and all the speeches both at the meetings and at the banquet. The pamphlet also contains the annual report of the secretary and treasurer, and a copy of the constitution and by-laws of the association, together with a complete list of all the members.

Trade Catalogues

Pneumatic Tools. Published by the Q & C Company, of Chicago and New York. 46 pages. Illustrated.

Hydraulic Tools. Published by the Watson-Stillman Company, of New York City. 44 pages. Illustrated.

The Safety Third-Rail System. Published by the Safety Third-Rail Company, of New York City. 16 pages. Illustrated.

The Westinghouse Compound Engine. Published by the Westinghouse Machine Company, of Pittsburgh, Pa. 94 pages. Illustrated.

List of Street Railway Patents

U. S. PATENTS ISSUED NOV. 22 TO DEC. 20, 1898, INCLUSIVE

Prepared for the STREET RAILWAY JOURNAL by THOMAS DREW STETSON

WEEK ENDING NOV. 22, 1898

Rolling Stock.—Henri J. Caillet, Paris, France. No. 614,697. Three claims.

Car Fender.—John D. Hodges, Chicago, Ill., assignor of five-sixths to James Bellew, Frank H. Repetto and Patrick J. King, same place. No. 614,654. Four claims.

Claim.—2. The combination of the rule-jointed fender frame, pivots upon which it swings and which constitute the hinge between its joints, the buffer, its bearing rods terminating in about a line with said hinge, a thrust rod in contact with the headed rear end of one of said bearing rods, and mounted in the rear section of the fender frame, a lever actuated by said thrust rod, a latch bolt with which said lever engages, a spring acting upon said latch bolt in opposition to the lever, and a latch hanger into which said bolt takes.

Indicator for Railway Cars.—Edouard Cros, Paris, France. No. 614,700. One claim.

Means for Driving Railway, Tramway or Automobile Cars.—Gustave Dupont and Maxime Johannet, Paris, France. No. 614,709. Four claims.

Claim.—3. In a motor vehicle, the combination of a front and rear axle of two counter shafts, a field magnet and armature mounted on each, a main shaft geared to both counter shafts, a reversible clutch on the main shaft and a single circuit including the armature of both dynamos, substantially as described.

Lubricating Car Wheels.—John V. Hawkey, Greensburg, Pa. No. 614,808. One claim.

WEEK ENDING NOV. 29, 1898

Nut Lock.—William H. Carruthers, Chicago, Ill., assignor to Marguretta E. Carruthers, same place. No. 614,835. Two claims.

Trolley for Electric Cars.—Hosea W. Libbey, Boston, Mass. No. 614,875. One claim.

Claim.—A trolley head having two arms between which the main trolley wheel is mounted and a bracket on each side between which and one of the arms is mounted a small contact wheel or roller substantially as and for the purpose set forth.

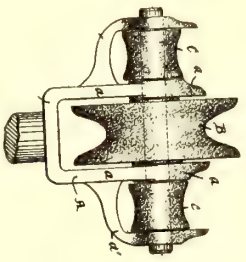
Rail Joint.—George F. Owen, Canal Winchester, Ohio. No. 614,885. Two claims.

Railway Rail.—John W. Peterman, Banta, Cal. No. 614,976. One claim.

Underground Conduit for Electrical Conductors.—Charles H. Sewall, Chicago, Ill. No. 614,995. Seven claims.

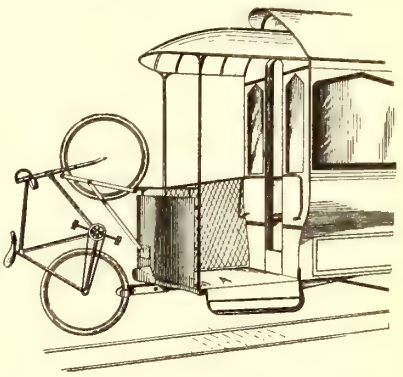
Claim.—1. The combination with a body of material having a conduit or conduits inclosed therein, of an inclosing layer or sheath of insulating material completely surrounding said body of material on the top, bottom and sides and effectively insulating the same from the earth to prevent the access of extraneous currents to the inclosed body of material, substantially as described.

Railway Switch.—George A. Penrose and Thomas F. Penrose, Meredith, Ark. No. 615,101. Three claims.



Nut Lock.—Silas Chambers, Sterling City, Tex. No. 615,139. Seven claims.

Electric Railway.—Hermann T. Hillischer, Vienna, Austria-Hungary. No. 615,176. Four claims.



Claim.—4. In an electric railway, the combination of the running rails, an inverted U-rail arranged parallel thereto, an electrical conductor carried in the hollow of said U-rail, but insulated therefrom, a channel or conduit between the said rails, a slot between the said rails leading to said channel or conduit, plates pivoted to the track rail along the conduit, springs acting upon said plates and tending to hold the same across said slot, a trolley running upon said rails, a curved contact arm carried thereby and running in said conduit, and rollers mounted in said trolley frame for depressing said pivoted plates *seriatim* to allow the said contact arm to pass along said slot, substantially as described.

WEEK ENDING DEC. 6, 1898

Bicycle Carrier.—Thomas C. duPont, Johnstown, Pa. No. 615,264. Two claims.

NO. 614,875

NO. 615,264

Claim.—1. The combination of a wheel holding frame, a brace pivotally secured thereto and supporting the same, and a brace block having a vertical slot for the passage, the brace and a cam slot for the end of said brace, said cam slot extending downward from the top of the brace block and curving outwardly at its lower extremity.

Street Car Motor.—Thomas D. Hoskins, New York, N. Y., assignor, by mesne assignments, to Sarah E. Warner. No. 615,274. Twelve claims.

Driving Gear for Motor Vehicles.—Joseph Millot and Benoit Millot, Gray, France. No. 615,360. Six claims.

Headlight Reflector.—Andrew Metternich, Newark, N. J. No. 615,490. One claim.

Claim.—In combination with a car having an interiorly located lamp, of an elongated tubular reflector extending through the wall of the car with its opposite ends flaring outwardly from a point between its ends; the inner flaring end of the reflector being independent of connection with said lamp and supported in a position opposite the latter with a space between the same, and its opposite outer end extending to a desired position to utilize the light from said interior lamp as an exterior headlight.

Truck Lifter.—William J. Donaldson, La Grange, Tex. No. 615,534. One claim.

Electric Locomotive.—Martin E. Thomas, Cassaday, Ky., assignor of three-fourths to W. F. Toops and H. L. Hendrick, Bowling Green, Ky. No. 615,592. Three claims.

Claim.—1. In an electric locomotive, a truck, a body mounted thereon through the medium of interposed springs, wheels mounted upon an axle journaled in the truck, a motor carried by the truck in gear with the axle, a dynamo carried by the body in electrical connection with the motor, an engine, a gear upon the axle, a gear journaled in the floor of the body and normally held in mesh with the gear upon the axle by a spring interposed between the floor of the body and the gear, a gear meshing with the said gear mounted upon a horizontal shaft, pulleys upon the said shaft and a belt connecting the pulleys with the armature of the dynamo, substantially as described.

Electric Locomotive and Truck.—Samuel M. Vauclain, Philadelphia, Pa. No. 615,594. Four claims.

Claim.—4. The combination in an electric motor or truck, of the frame, bearing blocks thereon, a motor, a motor shaft carrying the armature of the motor, said shaft being reduced at each end, a crank adapted to each end of the said shaft and keyed thereto, the ends of the shaft being threaded, nuts thereon confining the cranks to the shaft, the sleeves of said cranks extending through the boxes, wheels mounted on the sleeves, substantially as described.

Brake Handle.—Patrick Flood, Albany, N. Y. No. 615,614. Two claims.

WEEK ENDING DEC. 13, 1898

Wheel and Track Brake for Railway Cars.—Richard Shultz, Davis, W. Va. No. 615,917. Four claims.

Electric Arc Headlight.—William G. Wagenhals, Dayton, Ohio, assignor to the United States Headlight Company, Utica, N. Y. No. 615,927. Twenty-five claims.

Claim.—3. The combination with a vehicle propelled by electricity, of a case and an electric arc lamp contained therein, means

for detachably securing the case to the vehicle, a carbon-feed-operating device attached to the case, but disconnected from the lamp fixture, an upper carbon carrying rod adapted to slide in suitable guides attached to the lamp fixture, spring retracting feeding mechanism adapted to coact with said rod and said carbon feed operating device, means whereby the latter can be manipulated, and suitable connections with the lamp and the case and the vehicle whereby electric current is conveyed from the propelling power of the vehicle to and from the lamp.

Trolley Replacer for Electric Railways.—Lucian A. Cowles, Randolph, Mass. No. 615,966. Five claims.

Claim.—2. A trolley wheel restoring device composed of a forked lever, properly connected with the trolley pole and wheel, and having the ends 5, swinging guides, slotted and adapted to be moved by the ends of the forked lever, a spring hinge in said guides, proper mechanism for connecting and operating said lever and guides in connection with a trolley pole, and a spring normally holding said device out of action, substantially as and for the purposes described.

Hand Strap for Cars.—Edward P. Hendrickson, New York, N. Y. No. 615,986. Two claims.

Claim.—1. A hand strap for cars comprising a main portion and integral straps extending in opposite directions therefrom, a bar and means for uniting the straps together at their ends and to the bar so that loops are formed in the straps to receive the rail of the car and at the main portion for the hand, the straps being held in a diverging condition by the means aforesaid and the hand opening being parallel to the supporting bar, substantially as set forth.

Ball Bearing for Trolley Wheels.—George E. Mittinger, Jr., Cleveland, Ohio, assignor of three-fourths to Frederick J. Schweitzer, same place. No. 616,060. Six claims.

Claim.—1. A wheel having at each side a ball cavity situated at the center of rotation thereof, supporting bearing blocks having registering ball cavities, and a single ball in each pair of cavities, the balls projecting from the wheel cavities into the supporting block cavities and a connection for the supporting blocks passing around the wheel and adapted to permit it to freely revolve, substantially as described.

Trolley Wheel Replacer.—George E. Mittinger, Jr., Cleveland, Ohio., assignor of three-fourths to Frederick J. Schweitzer, same place. No. 616,061. Seven claims.

Claim.—6. A replacing section consisting of sheet metal tapered toward its outer ends and provided with a spiral groove formed by depressing the sheet metal, substantially as described.

Ball Bearing for Electric Motors.—John M. Murphy, Torrington, Conn., assignor of two-thirds to David F. Halsted, New York, N. Y., and William M. Keepers, Newark, N. J. No. 616,063. Four claims.

Week Ending Dec. 20, 1898

Controller for Motor Cars.—Arthur P. Dodge, New York, N. Y. No. 616,089. Six claims.

Claim.—1. In a motor operated by steam or like pressure, a boiler, a controller, comprising a valve, a central shaft, a hand wheel connected therewith, a piston and a cylinder on one side thereof connected with brake mechanism by a hydraulic column, a piston and cylinder on the opposite side similarly connected with a reversing mechanism, the sleeve surrounding the shaft and connected so as to operate the reversing piston and the hand lever with geared connections with the piston of the first named brake cylinder, substantially as described.

Car Fender.—Peter Heesem, Pittsburgh, Pa. No. 616,102. Three claims.

Claim.—1. A car fender comprising the frame provided at its forward portion with rollers mounted on a shaft 19, said shaft 19 being provided with a pinion at one end, in combination with a shaft provided at each end with a pinion, said shaft and pinions being adapted to be brought into engagement with the pinion on the shaft 19 and a gear wheel on the front axle of the car, substantially as set forth.

Nut Lock.—Raymond Hines, Cresson, Pa. No. 616,103. One claim.

Railway Switch.—Edwin S. Leaycraft, Jersey City, N. J. No. 616,120. Eight claims.

Claim.—1. A railway switch, consisting of a switch tongue, an armature operated by a magnetic device carried on a vehicle moving along the railroad track, an arm carrying said armature and oscillating transversely of the railroad track, and a mechanical connection between said switch tongue and armature whereby movements of the latter will be transmitted to the former, substantially as specified.

Combined Rail Joint and Device for Preventing Spreading of Rails.—Henry M. Williams, Fort Wayne, Ind., assignor of one-fourth to Franz Burger, same place. No. 616,171. Five claims.

Claim.—2. The combination with the parallel rails of a railway track, of a rail joint connecting abutting rails at one side of the track, and a tie rod formed at one end with a fork, the branches of which extend through openings of the rail joint and receive nuts at their ends, said rod extending across the track and being provided at its opposite end with a bearing for engaging the rail at the other side of the track, substantially as described.

Car Coupling.—Charles S. Park and George B. Park, Greenfield, Mass. Filed Feb. 8, 1898. No. 616,203. Two claims.

Extension Car Step.—William J. Griffiths, Jr., Mount Vernon, N. Y. No. 616,230.

Rail Bond.—Walter E. Harrington, Camden, N. J. No. 616,232. Six claims.

Claim.—2. In combination with abutting ends of railway rails, a bonding member with smooth contacting surface adapted to contact therewith, a temporarily plastic alloy intermediate said bonding member and the rails and set screws adapted to act upon said bonding member to maintain pressure between it and the rails, substantially as described.

Car Advertising Device.—Arthur H. Hieatzman, Baltimore, Md., assignor of one-half to Napoleon B. Lobe and Ernest M. Manger, same place. No. 616,235. Six claims.

Car Truck Equipment.—Sidney H. Short, Cleveland, Ohio. No. 616,264. Five claims.

Claim.—3. The combination with a truck and its supporting axles, a reservoir carried by said truck, a frame loosely journaled at one end on one of said axles, means for yieldingly suspending the other end of said frame from the truck, an air compressor mounted on said frame, and a pipe delivering from said compressor to said reservoir, as and for the purpose set forth.

Air Brake.—Murray Corrington, New York, N. Y. No. 616,288. Three claims.

Pneumatic Motor for Electric Appliances for Cars.—Clarence A. Evans, Upland, Pa. No. 616,301. One claim.

Valve for Pneumatic Motors.—Frederick W. Hedgeland, Chicago, Ill., assignor to The W. W. Kimball Company, same place. No. 616,323. Five claims.

Sprinkling Vehicle.—Arthur H. Howland, Worcester, Mass., assignor to Frederick C. Austin, Chicago, Ill. No. 616,334. Four claims.

Rail Joint.—William E. Smith, Telluride, Colo., assignor to himself and John Hebbard Adams, same place. No. 616,365. Six claims.

Claim.—6. In a rail joint, the combination of a chair, a pressure plate extending alongside the rail, and a toggle working between the chair and the pressure plate, the toggle having means for holding it in extended position.

Station Indicator.—Jefferson D. Barry, Marlin, Tex., assignor of one-half to A. L. Branson, same place. No. 616,393. Two claims.

Car Coupling and Operating Device Therefor.—Seth Bedford, Charleston, Mo. No. 616,395. Twenty-two claims.

Combined Bearing and Power Transmitting Device.—Carl O. C. Billberg, Lewisburg, and Paul A. N. Winard, Philadelphia, Pa. No. 616,396. Four claims.

System of Electric Traction.—Michelangelo Cattori, Rome, Italy. No. 616,403. Three claims.

Rail Joint.—Orlando Smay, Johnstown, Pa., assignor by mesne assignments, to the Lorain Steel Company, of Ohio. No. 616,440. Two claims.

Claim.—2. In a railway joint, the combination of rails having a portion of their entire web removed, two splice bars, one of which is formed with a projection and perforation, said projection serving in place of the said removed web and sustaining the head of the rails at all points necessitated by the removal of the web, a lug on the other of said splice bars, said lug extending through said perforation, and a key to engage said lug.

Nut Lock or Fastener Bar.—Irvin Y. Baringer, Perkasie, Pa., assignor of one-half to Thomas L. Kneile, Philadelphia, Pa. Term of patent, 14 years. Design 29,834. One claim.

Railway Rail.—George J. Capewell, Hartford, Conn. Filed Nov. 26, 1898. Serial No. 697,565. Term of patent, 14 years. Design 29,833.

We will send copies of specifications and drawings complete of any of the above patents to any address upon receipt of fifteen cents. Give date and number of patent desired. The Street Railway Publishing Company, Havemeyer Buidding, New York.

Financial Notes.

AKRON, OHIO.—The property of the Akron Street Railway & Illuminating Company has been appraised at $932,000, and will be sold to a reorganized company, of which Samuel Thomas is at the head. The new company will be capitalized at $2,000,000. The present outstanding indebtedness of the company is $1,200,000, one-half of which will be done away with. The present bondholders will be given preferred 5 per cent stock to the amount of $600,000, in place of the amount of bonds now held. In addition to this, bonds to the amount of $300,000 will be issued to provide for the entire rebuilding of the lines and the purchase of new rolling stock.

BALTIMORE, MD.—The Baltimore & Northern Electric Railway Company, backed by a syndicate of capitalists headed by Alexander Brown & Sons, of Baltimore, have purchased the Baltimore City Passenger Railway Company. The terms of the sale are $90 per share, cash, involving a total of $12,600,000. The directors of the Baltimore City Passenger Railway Company have ratified the sale, subject to the decision of the stockholders. It is understood that the lines will be rearranged, and that the motive power of the Red & White lines will be changed from cable to electricity.

BALTIMORE, MD.—The capital stock of the Baltimore Consolidated Railway Company is to be increased from $9,172,000 to $9,672,000, to meet the expense incurred by the construction of the extension to Ellicott City. Present stockholders will be allowed to subscribe for the new issue at par in amounts proportionate to their holdings.

BALTIMORE, MD.—The Consolidated Railway Company has decided to issue $500,000 additional stock, which will be offered to the present stockholders in proportion to their holdings at par. The company has outstanding $9,172,000, and its authorized capital is $10,000,000.

BOSTON, MASS.—The West End Street Railway Company has declared a semi-annual dividend of 4 per cent., payable Jan. 2 by the Boston Elevated Railway Company.

BROOKLYN, N. Y.—The Brooklyn Rapid Transit Company reports earnings as follows:

November.	1897.	1898.
Gross receipts	$417,818	$446,501
Five months ending Nov. 30.		
Gross receipts	2,271,539	2,614,732

BUFFALO, N. Y.—The Buffalo Railway Company has declared a quarterly dividend of 1 per cent, payable Dec. 15.

CHATTANOOGA, TENN.—The Chattanooga Electric Railway Company has filed a consolidated mortgage to secure $625,000 of 5 per cent bonds, with the Maryland Trust Company, of Baltimore, as trustee. The new mortgage takes the place of the $625,000 old bonds now existing, the object being to reduce the interest from 6 to 5 per cent.

CHICAGO, ILL.—Stockholders of the Chicago & St. Louis Electric Railway Company, which was organized several years ago to build an electric railway from Chicago to St. Louis, are, it is said, considering an investigation of the affairs of the company.

CHICAGO, ILL.—The Chicago City Railway Company proposes to increase its stock at the annual meeting to be held in January, from $12,000,000 to $14,000,000, the stockholders to be given the right to subscribe. The company has declared a dividend of 3 per cent, payable Dec. 31.

CHICAGO, ILL.—The West Chicago Street Railroad Company recently declared a quarterly dividend of 1½ per cent.

CLEVELAND, OHIO.—It is reported that an English syndicate is negotiating for the purchase of the property of the Cleveland City Railway Company, the Cleveland Electric Railway Company and suburban roads.

DENVER, COL.—The Denver City Railroad has been sold at auction, by order of the United States Court, under foreclosure of a mortgage for $4,000,000. Frederick P. Olcott, of New York, chairman of the reorganization committee, secured the property for $500,000, the minimum bid allowed. The West End Street Railway was also sold under foreclosure, being purchased by the same party for $40,000.

CHICAGO, ILL.

BRANCH OFFICES:

100 Broadway, NEW YORK.
109 Endicott Arcade, ST. PAUL.
17 Place d'Armes Hill, MONTREAL.
537 Mission St., SAN FRANCISCO.

GREEN BAY, WIS.—Upon the application of M. Joannes and Thos. W. Spence, receivers of the Fox River Electric Railway Company, Judge Hastings has signed an order for the sale of the property on Jan. 14. The sale will be held at the office of the Sheriff of Brown County, at 9 A. M.

LANCASTER, PA.—The report of William B. Given, receiver of the Pennsylvania Traction Company, for the past year shows an increase in passengers carried of 274,779 over the previous year, and an increase of $15,005.31 over last year in receipts. A decree has been entered, by the United States District Court, for a final adjustment of all accounts. A committee of reorganization has been appointed and a charter applied for.

MERIDEN, CONN.—The Meriden, Southington & Compounce Tramway Company has prepared a petition to the General Assembly for permission to increase its capital stock to $500,000, with rights to build and extend its tracks from Milldale to Mt. Carmel, Waterbury, Meriden and Berlin, by an independent route, to Plainville from Southington, from Dunham's to Compounce Lake, and to build a cable road to West Peak.

NEW YORK, N. Y.—The car barn of the Union Railway Company, situated at Woodruff avenue and Boston Road, was totally destroyed by fire recently, together with a number of cars and supplies. The loss is estimated at $150,000.

OSWEGO, N. Y.—Justice Wright, of the Supreme Court, has granted the motion of the Knickerbocker Trust Company, of New York, to foreclose bonds against the Lake Ontario & Riverside Railway Company for $125,000. The property has been ordered to be sold within two months.

PORT CHESTER, N. Y.—The Highway Commissioners of Harrison have granted the Port Chester Electric Railway Company a franchise through that part of the town lying between Rye and Mamaroneck.

PROVIDENCE, R. I.—The Providence and Taunton Street Railway Company has declared a dividend of 2½ per cent, payable Jan. 2.

QUEBEC, QUE., CAN.—Notice is given that the Quebec, Montmorency & Charlevoix Railway Company will make application, at the next session of the Parliament of Canada, for an act amending the act incorporating the said railway company, viz.: To change the name of the company to the Quebec Railway, Light & Power Company; to ratify and confirm the purchase of the property and franchise of the Quebec District Railway Company; to authorize the company to build a line, or lines, of railway or tramways in Levis, Bellechasse, Dorchester, Beauce and Lotbiniere Counties; to ratify and confirm the purchase of the property, works and capital stock of the Montmorency Electric Power Company; to authorize and empower the company to carry on the business of the Montmorency Electric Power Company; to acquire water powers, and to maintain the construction necessary to improve or utilize the same; to expropriate for the purpose of placing poles and carrying wires; to authorize the purchase of gas and lighting companies.

ST. LOUIS, MO.—Negotiations, which have been in progress for more than three months, have resulted in the sale to a New York syndicate, represented by Brown Brothers, of the Lindell Railway and the Missouri Railroad systems for $8,500,000. The papers completing the sale have been signed and the actual transfer will be made in a few days. The purchase price paid is on the basis of $174 a share for Lindell stock and $192 for Missouri. Nearly every part of the west and southwest portions of St. Louis are reached by the two systems.

ST. CLOUD, MINN.—The car barn of the Benton Power & Traction Company was destroyed by fire recently. Four passenger cars, a snow plow and the building were completed destroyed, entailing a loss of $15,000; partly insured.

SPRINGFIELD, OHIO.—The stockholders of the Dayton, Springfield & Urbana Electric Railway Company have authorized an increase of the capital stock of the company from $10,000 to $750,000.

WASHINGTON, IND.—Ziba F. Graham, formerly general manager of the Washington Street Railway Company, has purchased, at sheriff's sale, the property of said company for $12,500.

ZANESVILLE, OHIO.—A number of Philadelphia capitalists have inspected the lines of the Zanesville Street Railroad, relative to purchasing the same at the receiver's sale, to be held January 3.

Street Railway Journal

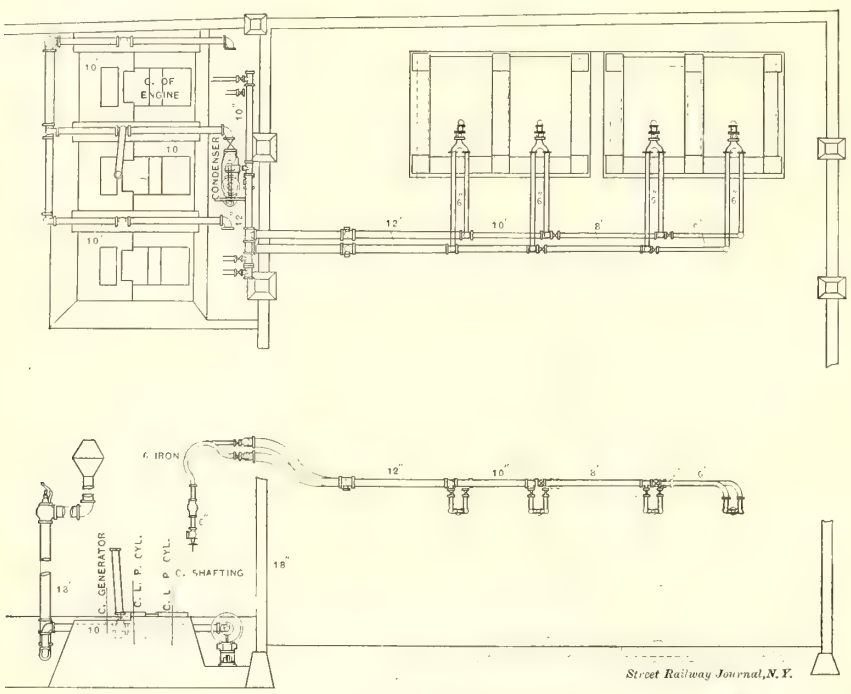
VOL. XV. NEW YORK AND CHICAGO, FEBRUARY, 1899. No. 2.

LIBRARY U. FEB 6 1899 PATENT OFFICE

ELECTRIC RAILROADING IN THE ARGENTINE

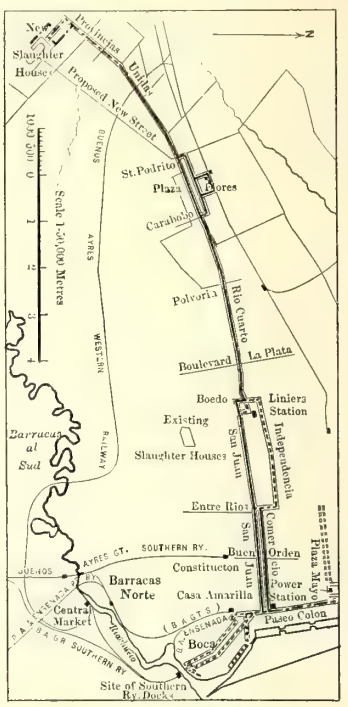
Buenos Aires, the largest and most important city in South America and the capital of the Argentine Republic, is situated on the River Plate, which is here about 30 miles wide. The majority of the inhabitants of the city are descendants of the Spaniards who have settled in the country during the last 300 years, but there is also a very large number of foreigners, among whom the Italians are probably the most numerous. The houses are generally of brick, and are usually one story in height. With the rapid immigration which has been setting in the direction of the Argentine and its capital during the past few years, the city has grown and is growing rapidly. The present population is not far from 850,000, and, at the present rate of increase, will probably reach 1,000,000 in three or four years.

OPENING DAY, LA CAPITAL TRAMWAYS, BUENOS AIRES



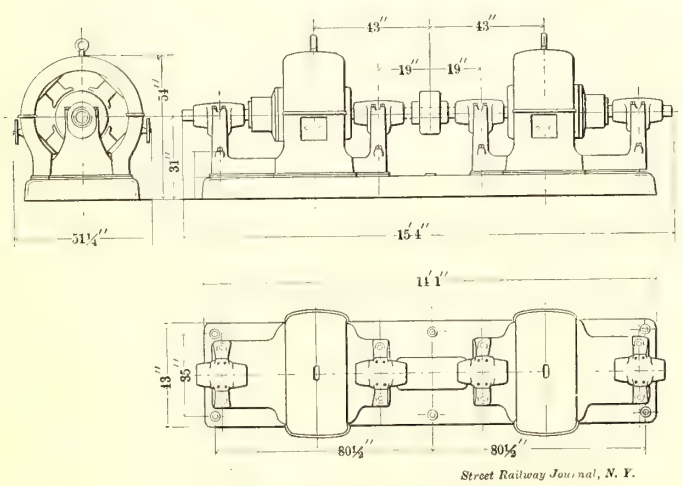
The great extent of the city makes street railway riding a necessity, and as a result the street railway systems have had an extensive development. Every street in the older part of the city, for a territory covering about two square miles, is traversed by a street railway line, with the exception of one short avenue, the shopping street of the city, from which tracks have been rigorously excluded. The streets in this part of the city are, for the most part, narrow, so that only one track is allowed on a street, and the cars of a line run down one street and up another, making most of the mileage single track. The average width of the streets in this section of the city, from curb to curb, is 25 ft., and the tracks are laid on the left-hand side of the roadway, leaving room for only one line of vehicles, which are obliged to run in the same direction as the cars, so that all traffic on every street in this portion of the city is in one direction only. The sidewalks in these narrow streets are usually but 4 ft. in width. In the newer part of the city, where the streets are 50 ft. wide or above, double-track construction is allowed.

A list of the street railway companies in Buenos Aires, with mileage and a general description of the street railway conditions in that city, was published in the STREET RAILWAY JOURNAL for July, 1898. The railway companies have generally a London office, and they are owned in large part by English capital. Horses are used for the most part, and only two systems have yet adopted electricity. Horses and fodder are cheap, an excellent horse bringing only about $25, while coal is expensive. It is nearly all shipped from Wales, and costs from $6.50 gold per ton up. Nevertheless, the railroads which have

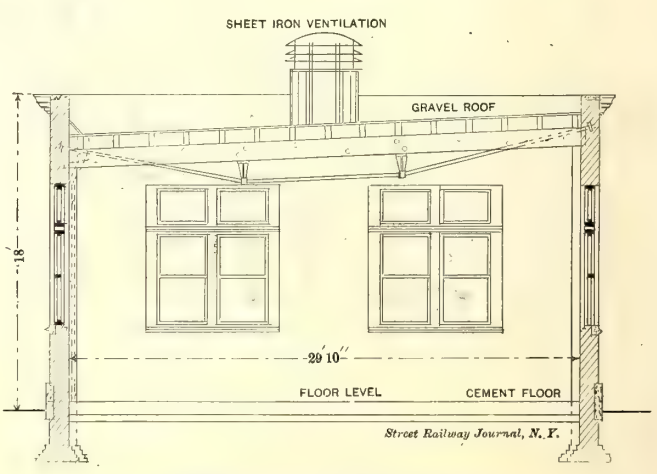


adopted electricity speak favorably of the economical results secured, and electric equipment is being rapidly forwarded.

The companies which have already installed electric power on their lines are the La Capital Tramways Company, the greater part of which, comprising about 8¼ miles of double track, is now in operation by electric power, and the Buenos Aires & Belgrano Railways, or Bright's concession, of which a short section now employs electric traction, but which is being rapidly equipped throughout with the improved power.



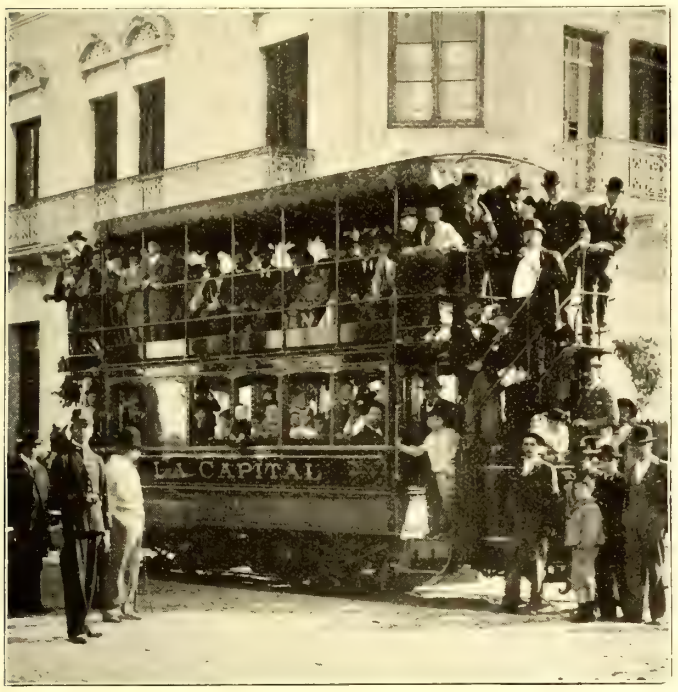
The system of the La Capital Tramways Company, with



PLAN AND SIDE ELEVATION OF PIPING

MAP OF SYSTEM

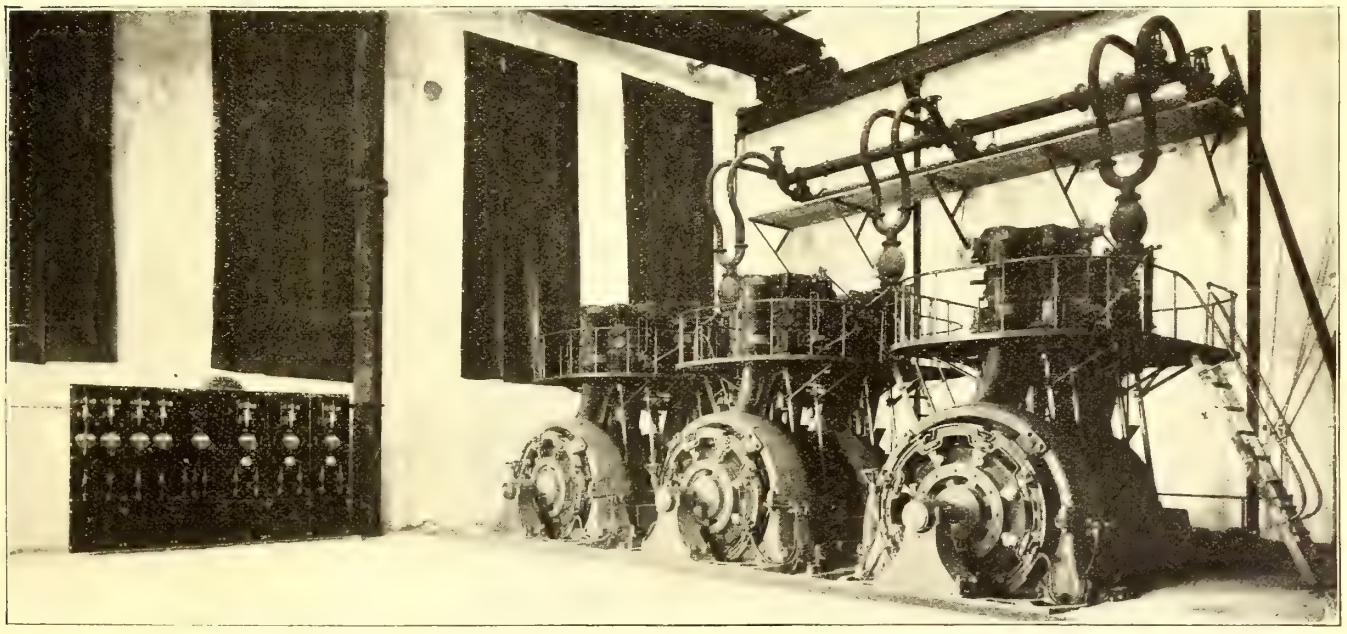
BOOSTER FOR BATTERY



SECTION OF BATTERY HOUSE

which this article directly deals, reaches from the center of the city almost due west to New Chicago, where the government slaughter houses are located, and handles not only a large passenger business but also a large business in the transportation of fresh meat from that point to the city. Some reference has already been made to this traffic in former issues, and as it constitutes a very important branch of the transportation business of the city, and one which might be followed to advantage in other southern cities where the refrigeration of meat is not followed to any considerable extent, some particulars of it may be of interest. The present slaughter houses of Buenos Aires were built by a French company in 1889, at a cost of several million dollars. They have been purchased since by the Government, which rents stalls to the meat purveyors. All the meat consumed in the city comes from these houses, and as there are no refrigerating methods for preserving meat in general use, cattle are killed and the meat distributed to be eaten the same day. The La Capital Company has a contract for transporting all this meat to the city, and about 600 tons are carried on its cars and delivered to about thirty large markets located in different parts of the city. The butchers commence work about 2 o'clock in the morning and all the meat is delivered to the retail markets before 9 o'clock the same day. The special cars for handling this meat were illustrated in the Street Railway Journal for November, 1898, and January, 1899.

The power station of the La Capital Company is located in the old part of the city, near the end of the line and close to the docks. It consists of a framing of steel, supplied by the Berlin Iron Bridge Company, and filled in with brick between the steel columns. The engine room contains three Ball & Wood vertical compound engines of 450 h.p. directly connected to three Walker generators. The piping is in duplicate, and was furnished by Best, Fox

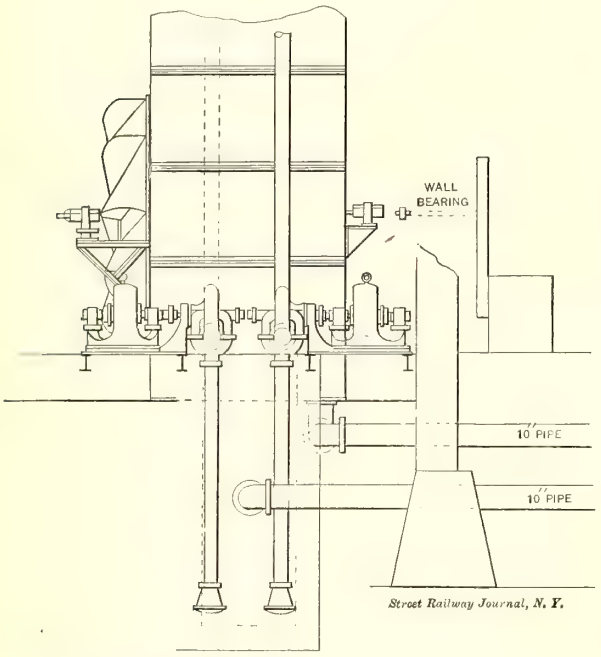


& Company. The arrangement of the piping is shown in the plan view of the station, and under normal conditions of working both sets of duplicate pipes are in continuous use. In case of an accident to one set the other is run at slightly higher pressure until the trouble is remedied. Bent pipe is used instead of elbows. The boilers are of the Stirling type, four in number, and of 350 h.p. each. Green economizers and Worthington compound feed pumps are used, and an induced draft apparatus, supplied by the B. F. Sturtevant Company, is employed. The fans

STANDARD CAR

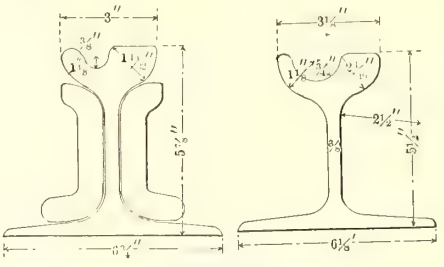
BOILER ROOM

VIEW OF ENGINE ROOM—LA CAPITAL TRAMWAYS COMPANY



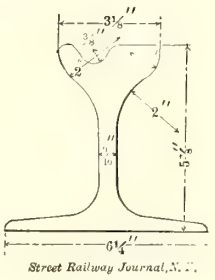
can be run by electric motor or separate steam engine, as desired, but the motor is usually employed. The fans are in duplicate, but arranged with a clutch so that one or both can be driven by either engine or motor. The induced draft apparatus and economizer are both placed over the boilers, as will be seen on the diagram, and by-passes are arranged to cut the economizer out of service if desired. The condensers are of the Conover type, and Barnard cooling towers, supplied by the Wheeler Condenser & Engineering Company, are in use. The management speak in favorable terms of the use of induced draft, which, under the circumstances existing in Buenos Aires, is particularly valuable. In that city heavy showers come up suddenly, and when these occur the people crowd into the cars, throwing a sudden load on the power station. The use of induced draft enables the station engineer to force the boilers up quickly at these times, and thus take care of this sudden load. The ability to force the boilers at will is also valuable in taking care of the evening pleasure load, which, in summer, is often very heavy.

The company has recently installed, close to the station, a chloride accumulator battery of 1000-h.p. hours capacity for station regulation, and also one of about the same size

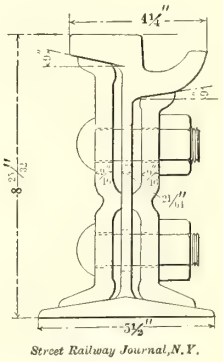


at about half a mile from the further end of the line for maintaining the necessary pressure at that point. Both batteries are fitted with motor-driven boosters; that for the distant battery is a shunt-wound machine of the ordinary type, with current always flowing in the same direction and at about 150 volts. The booster for the station battery is of the differential type. Both boosters were supplied by the Bullock Electric Manufacturing Company.

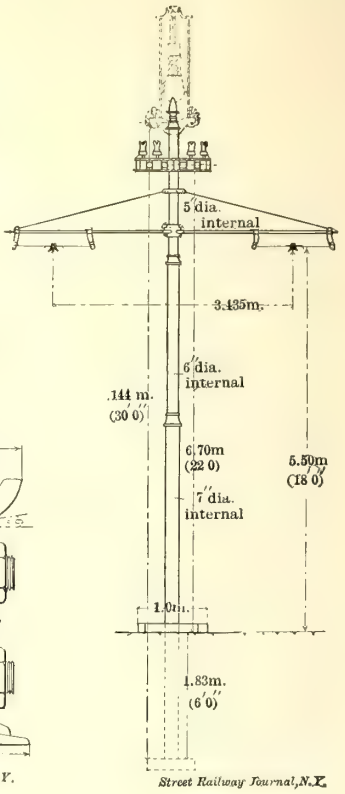
The track construction, when the electric equipment was first commenced, was that used formerly with horse traffic. The rails were quite soft and of the section shown herewith. An attempt was made to utilize these on part of the line, but it was finally decided advisable to replace them with a modern 9-in. 90-lb. girder rail in the city and a 7-in. 70-lb. rail in the suburbs. The section now employed is that shown above, the grooved rail being compulsory. The 9-in. rails were supplied by the Lorain Steel Company, and the 7-in. rails by the Pennsylvania Steel Company. They are in 30-ft. lengths, as it was found impossible to ship the 60-ft. lengths. They are mounted on 4-in. x 6-in. ties of *colorado quebracho*, which is a native wood, dark red in color, and so hard that spikes cannot be driven into it; holes, therefore, have to be bored for their reception. Ties of this wood practically last forever. They cost about 75 cents apiece, are spaced 2 ft., center to center, and are mounted on 6 ins. of concrete. The joints on the 9-in. rail are all of the twelve-bolt type and most of the track is double bonded with the Brown plastic bond. The special work was supplied by the Lorain Steel Company and the Pennsylvania Steel Company.



In the original construction tie-rods were used, but it was found that the heavy carts which are in use in this

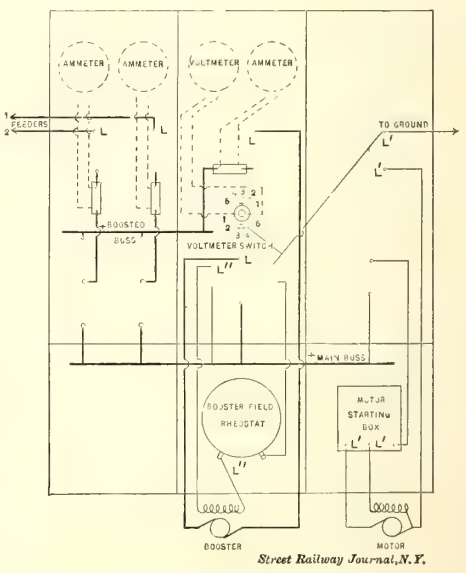


CIRCULATING PUMPS FOR COOLING TOWER



OLD RAILS

OLD RAIL



NEW RAIL

POLE

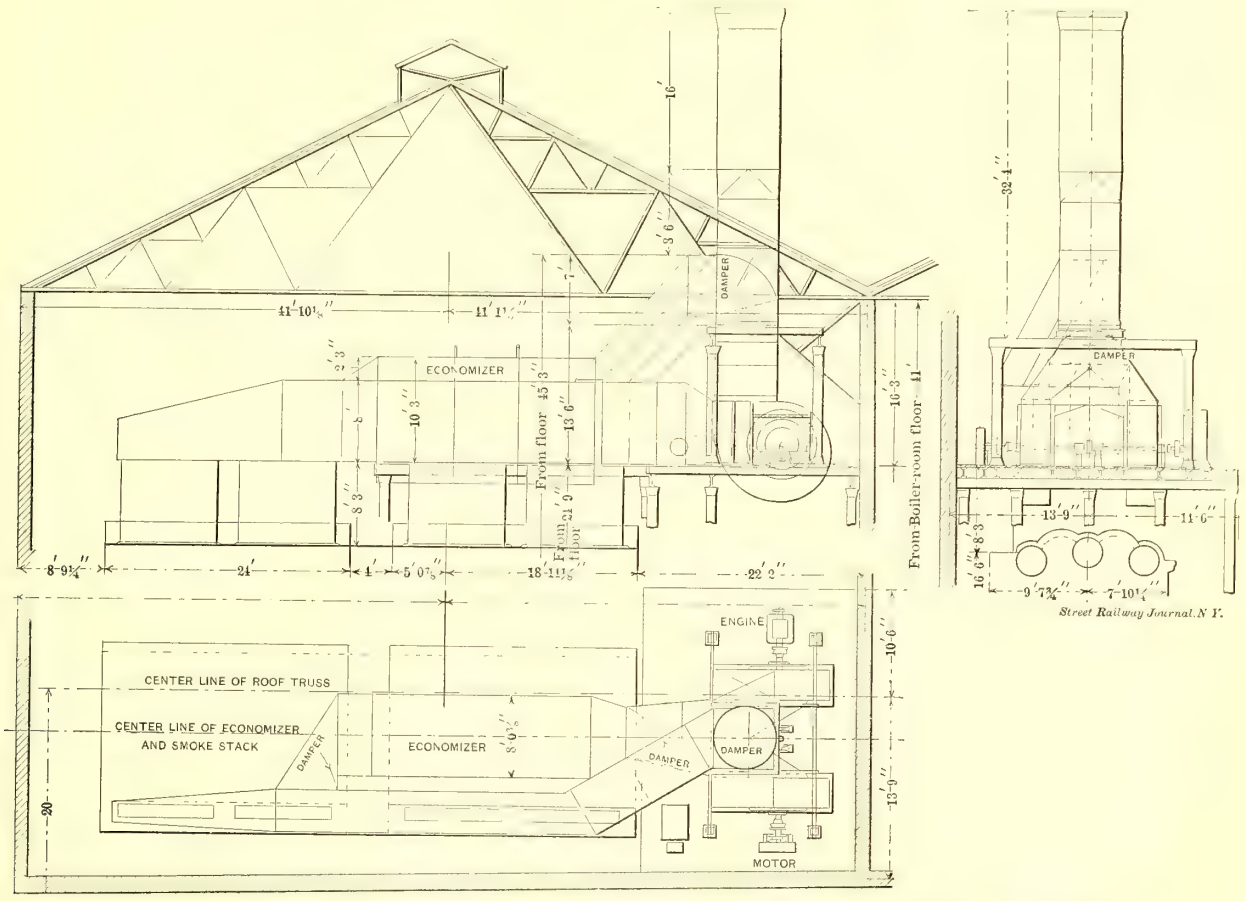
TYPICAL SCENE ALONG ROUTE

CONNECTIONS OF STORAGE BATTERY SWITCHBOARD AT POWER STATION

country broke off the ends of these rods, so that now braced tie-plates are being installed in their place. These native carts weigh from ten to fifteen tons each, and are fitted with wheels about 10 ft. in diameter. They are drawn by bullocks.

All feeders from the power station to Entre Rios, a distance of 1½ miles, are carried underground in creosoted wooden ducts; the rest of the feeders are carried overhead. The line was constructed by the Ansonia Brass Company. A number of poles in the center of the city carry arc lights. All the streets are paved either with stone blocks or native wood, and all paving is done by the company.

The cars are all of the double-deck type, with 18-ft. bodies. They were built by the J. G. Brill Company, and are mounted on Brill 21 E trucks. They are equipped



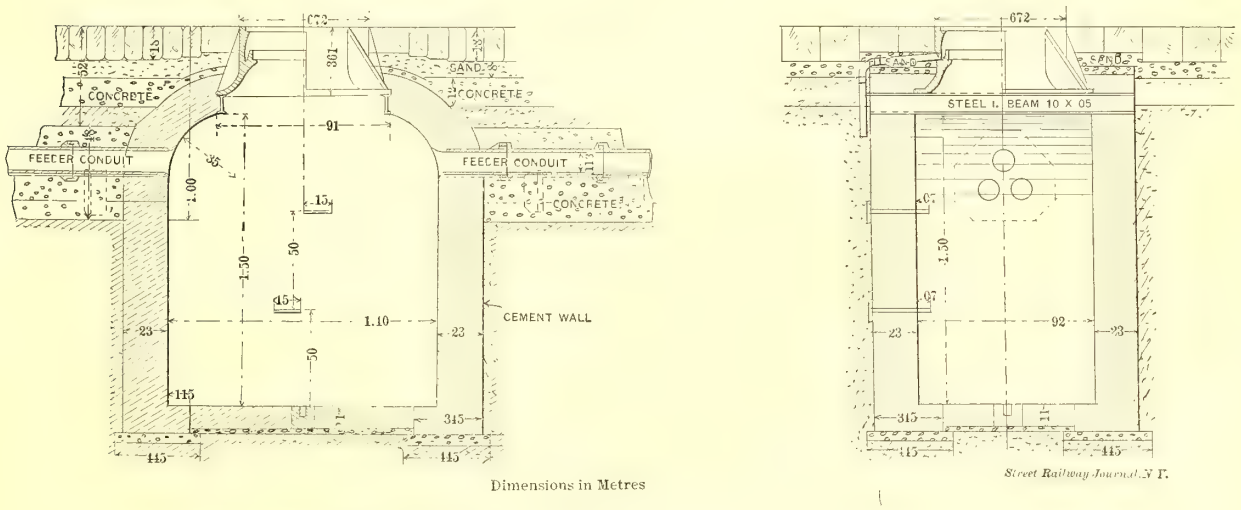


DIAGRAM SHOWING ARRANGEMENT OF ECONOMIZER AND INDUCED DRAFT APPARATUS

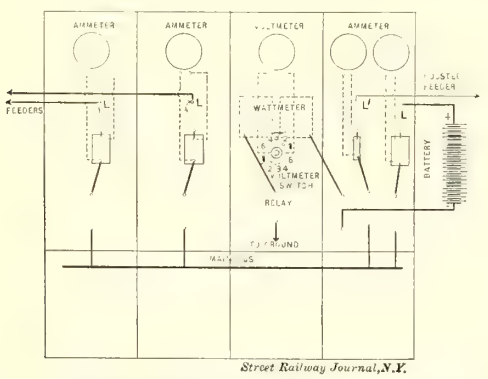
LONGITUDINAL AND CROSS SECTIONS OF MAN HOLE

Below Entre Rios iron poles with ornamental brackets are employed; beyond that point wooden poles are in use. The iron poles, which were supplied by Morris & Tasker, are all fitted with what are called refuges; these consist of a raised area at the base of the pole, about 39 ins. square and 6 ins. high, formed by curb stones and paved in the middle. The line appliances were supplied by H. W. Johns Manufacturing Company and A. & J. M. Anderson, and the feeders and the trolley wire by the Ansonia Brass Company. A number of poles in the center of the city carry arc lights. All the streets are paved either with stone blocks or native wood, and all paving is done by the company.



The cars are all of the double-deck type, with 18-ft. bodies. They were built by the J. G. Brill Company, and are mounted on Brill 21 E trucks. They are equipped with short platforms, and are all of short length on account of the narrow streets in the old part of the city, which would prevent the use of a longer car. The double decks are employed on account of the variable climate, which makes some passengers prefer an open car and others a closed car. The management reports that no accidents have followed the use of double-deck cars, and they seem well suited for the conditions existing in Buenos

Aires. The usual European regulations in regard to limiting the number of passengers on the cars are in force, and only four people are allowed to stand on the front platform and six on the rear platform. The climate is about similar to that in Richmond, Va., and no car heaters are required. At present one motorman and two conductors are employed on each car, one conductor for the lower deck and one for the upper deck. Practically all of the motormen and conductors are Italians, as the natives of the country do not seem to take to the work. The wages paid are about $2.25 in paper, which is equivalent to about 80 cents in gold.

LAYING TRACK

The officers of the company are: President, Theo. N. Vail; secretary and treasurer, H. Roberts Parrish; consulting engineer, E. T. Birdsall, M. E.; resident general manager, Charles R. Thursby, C. E.; resident chief engineer, J. W. McCrosky.

Street Railway Journal, N.Y.

STORAGE BATTERY CONNECTIONS AT BOOSTER STATION

Electric Railroading in Milwaukee

Perhaps the heaviest daily car service on any American street railway is that given by the Milwaukee Electric Railway & Light company, of Milwaukee, from Milwaukee to Waukesha. The distance between these two points is 20 miles, and the winter service is given by two cars, which make the distance in about fifty-five minutes, an allowance of five minutes' wait being made at each end. Each car makes nineteen trips a day, or 380 miles in toto. The cars are double truck, and are made by the Barney & Smith Company.

The fare from Milwaukee to Waukesha is 35 cents single trip, and 50 cents round trip, which is considerably lower than the competing railroad fare, and the electric railway has taken nearly all the business away from the steam railroad. The line to Waukesha has been recently rebuilt, and is in magnificent condition. A large portion of it is over private right of way. A short time ago, on the invitation of General Manager Beggs, Henry Villard and other largely interested stockholders of the North American Company, and Edward E. Higgins, editor of the Street Railway Journal, made a trip over this line to Waukesha in fifty minutes, the speed at places being as high as 45 miles per hour.

EXTERIOR OF POWER HOUSE

OX CARTS IN COMMON USE IN BUENOS AIRES

The Milwaukee Company's lines now extend south from Milwaukee also as far as Racine and Kenosha, a distance of about 26 miles from the center of Milwaukee, and it will probably be but a short time before the intervening gap between the end of this line at Kenosha and the Chicago & Evanston Railway, now building northward from the Chicago city limits, will be filled up by a connecting railway, completing a through electric railway between Chicago and Milwaukee.

Electric Railways in Madrid and Barcelona

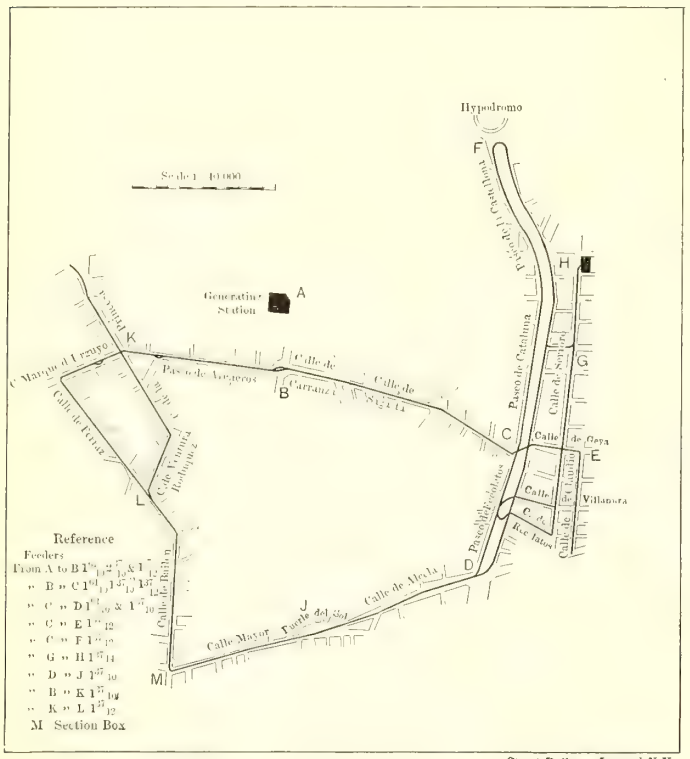
BY F. C. ARMSTRONG.

In spite of the fact that war was being waged last summer by Spain, the streets of Barcelona and Madrid, the two most important cities of the Iberian peninsula, presented scenes of great activity on account of the introduction of electric tramways in both cities by British capital. It is but just to say here that although the sympathies of Great Britain in the late war were supposed to be with the United States, the engineers who were engaged in the work of tramway installation in Spain were not molested in any way, although most of them were Englishmen and among them were a number of Americans.

Perhaps no nation in Europe is less understood by the English speaking people as a whole than the Spanish. While nearly all the other countries on the Continent are overrun each summer by tourists from England and America, comparatively few venture into Spain. As a result many people have formed their ideas of the Spanish from Cervantes' famous novel, and have the impression that they are a brave, chivalrous, but unpractical nation, romantic and dreamy, with little desire for modern improvement and with no habits of industry. While Spain as a nation has suffered from many causes which it is not the purpose of this article to discuss and which have repressed enterprise, both individual and corporate, the Spanish nature is far from being an idle one, and the average workman bears a striking resemblance to the French peasant in his qualities of frugality, temperance and capability for work.

The city of Madrid, the capital of Spain, is very similar in appearance to many other European capitals of the same population, with broad streets and fine buildings, many parks, amusements and manufactures. Barcelona, the largest city in population in Spain, is, on the other hand, a typical seaport town. Most of the houses are of brick, and many of them particularly in the new part of the city, are of hewn stone and of imposing appearance. It is the seat of various manufactures, a number of which are silks, woolens, cottons, calicoes, etc.

The Tranvia de Madrid is owned by an English company, the Tramways Union Company, Winchester House, Old Broad Street, London, which is also the owner and operator of several other continental tramways. The company's lines in Madrid cover the principal streets of the city, and are approximately 17 miles in length. The Barcelona Tramways Company, Limited, is also an English corporation, with offices at the same address in London, and the routes of the two systems are shown in the accompanying maps. When the electric equipment of both lines was decided upon, Alfred Dickinson & Co., the well known English electrical engineers, were appointed engineers to supervise the installation and tenders were requested from thirty firms for the electrical equipment of both lines. In October, 1897, the contract was finally awarded to Dick, Kerr & Co., Limited, of London, for the complete equipment required for the conversion of both systems. The equipment is similar in many respects, as will be seen from the following description:

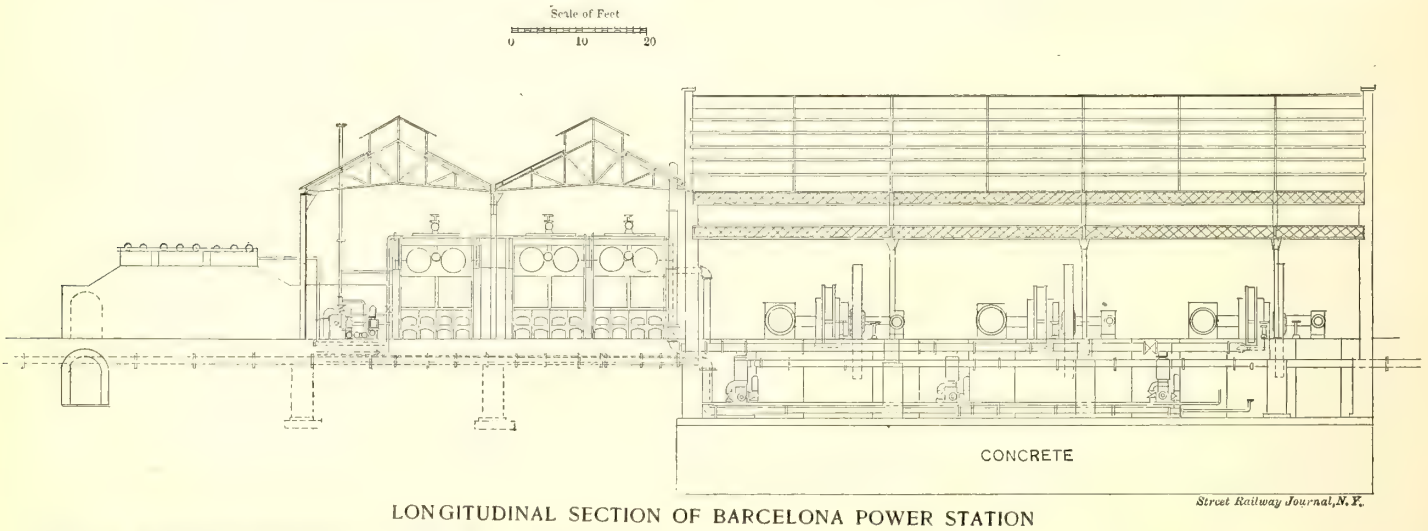


VIEW OF NEW ELECTRIC LINE AT MADRID

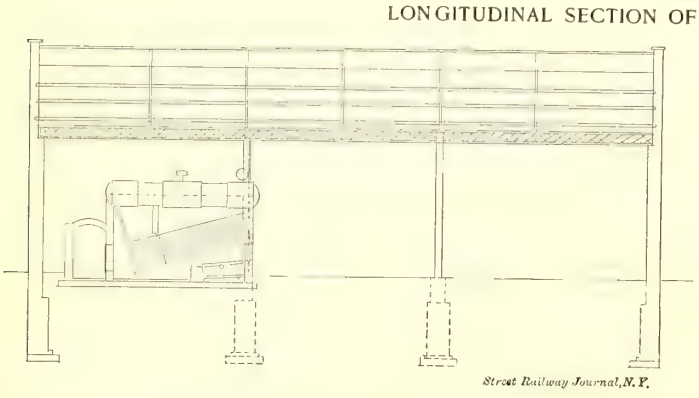
POWER STATIONS.

The power station at Madrid is equipped with two water tube boilers, each having 3654 sq. ft. heating surface, and

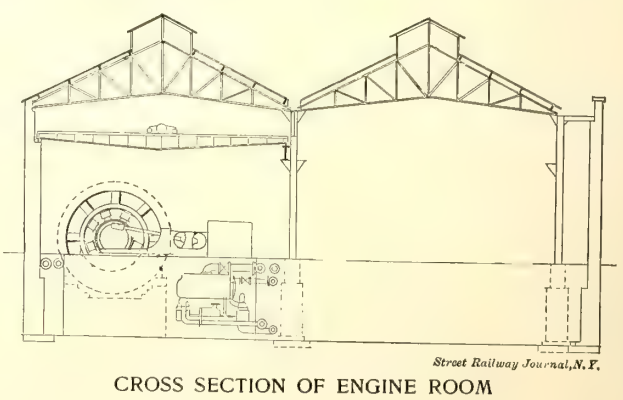
working at a pressure of 8 atmospheres. The engines are of the Corliss type, cross-compound, having cylinders 20 ins. and 40 ins.x42 ins. stroke. They are coupled direct to compound wound multipolar generators of 425 kw. capacity. Each power unit is provided with an independent Admiralty type surface condenser, operating in conjunction with a cooling tower. This tower has a capacity of dealing with 50,000 lbs. of steam per hour. It is provided with fans for creating an artificial draft, but so far the load has never been sufficiently heavy to necessitate these being put in operation. Indeed, when the full power tests were being made, 800 h.p. was dealt with for twelve consecutive hours, and, strange to say, the water in the reservoir was found to be 3 deg. cooler at the end of the run than at the start. Piping is arranged on the loop system, and consists of mild steel with flanges shrunk on and brazed; all elbows, T-pieces and special fittings are also of mild forged steel and the valves are of specially heavy design.



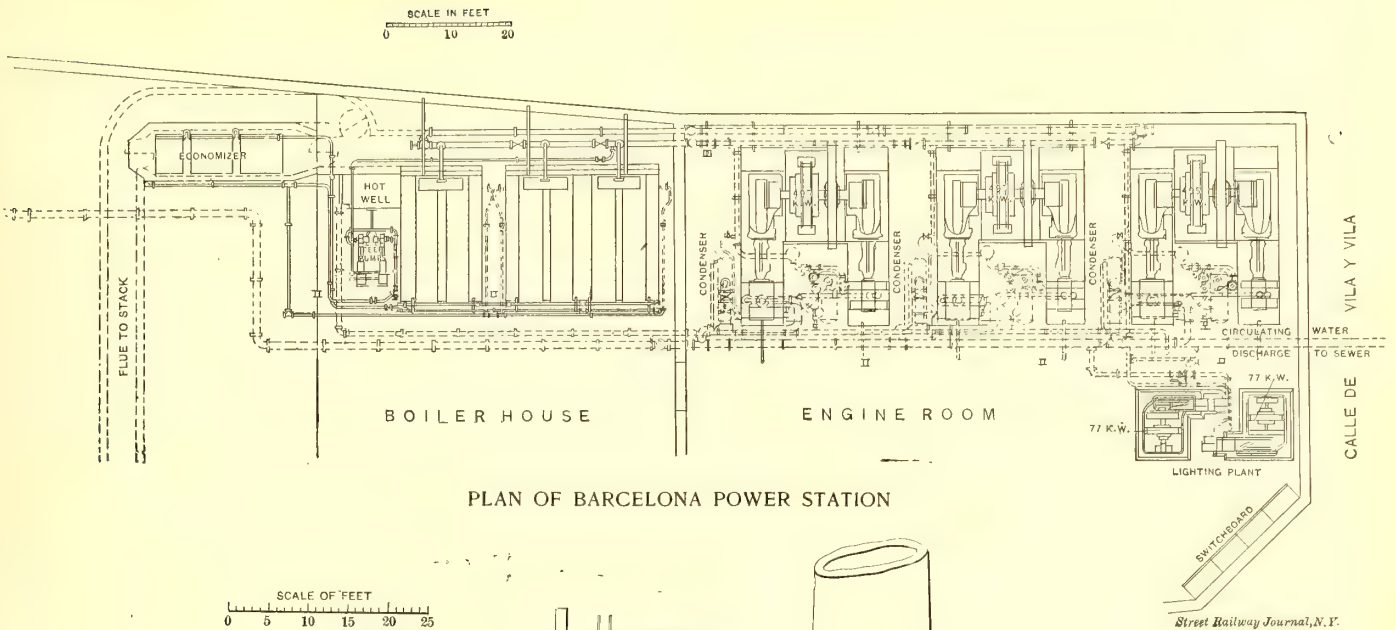
From the generators the current is conducted to the



MAP OF MADRID TRAMWAYS



MAP OF BARCELONA TRAMWAYS



LONGITUDINAL SECTION OF BARCELONA POWER STATION

PLAN OF BARCELONA POWER STATION

SECTION OF MADRID POWER STATION

STANDARD RAIL

PLAN OF MADRID POWER STATION

switchboard by lead covered cables. The switchboard is arranged on the usual panel system, there being three generator panels, a main output panel and seven feeder panels. In addition to these there is a Board of Trade panel, as the system has been laid with the view to complying with the Board of Trade regulations as to drop and rail return. There is also a special lighting panel which is arranged so that current can be taken either from the supplementary unit or from the main bus bars and distributed to the several lighting circuits.

The power station of the Barcelona tramways is located near the shore close to the southern end of the system, as will be seen from the map, this selection being dictated by the high price of coal in Barcelona and the necessity of operating, condensing and of reducing the transportation charges on fuel. Owing to the treacherous nature of the soil at this point, the foundations were made extremely broad, that for the chimney, which was to be 200 ft. high, being especially elaborate. After considerable investigation, it was finally decided to make the base of the foundation 54 ft. sq. Concrete was first laid to a depth of 4 ft. 1 in. Upon this was placed a layer of 6-in. railroad rails, laid close together, and above these rails was a layer of concrete 2 ft. 5 in. deep; another layer of rails was then laid in a reverse direction and another layer of concrete 2 ft. 1 in. was placed upon these rails; above this was placed a third layer of rails, then 2 ft. of concrete, and finally, 11 ft. 6 ins. of brick work. By this arrangement of raft foundation, the total weight of the chimney on the foundations was reduced to less than 2 tons per superficial foot.

BULL FIGHT AT MADRID

STREET SCENE, MADRID

The boilers are of the water-tube type, and have the same heating surface as those in Madrid, and are equipped with feed pumps, hot well and economizers. The engines are of the Corliss type with similar cylinder dimensions to those in Madrid, and are each directly coupled to a 425-kw. generator. The piping in this station is on the same general plan as that in Madrid, as shown in the plan of both stations, and in each station there is a small supplementary steam dynamo equipment for use in operating all-night cars and car-house lighting. There are two of these at Barcelona and one at Madrid, each consisting of a horizontal tandem compound engine coupled to a 75-kw. multipolar compound wound dynamo. If necessary, these units are also to be used as boosters for the long-distance transmission.

STANDARD CAR, MADRID

POWER STATION, MADRID

VIEWS OF TRAMWAY AND TRAMWAY CONSTRUCTION IN BARCELONA

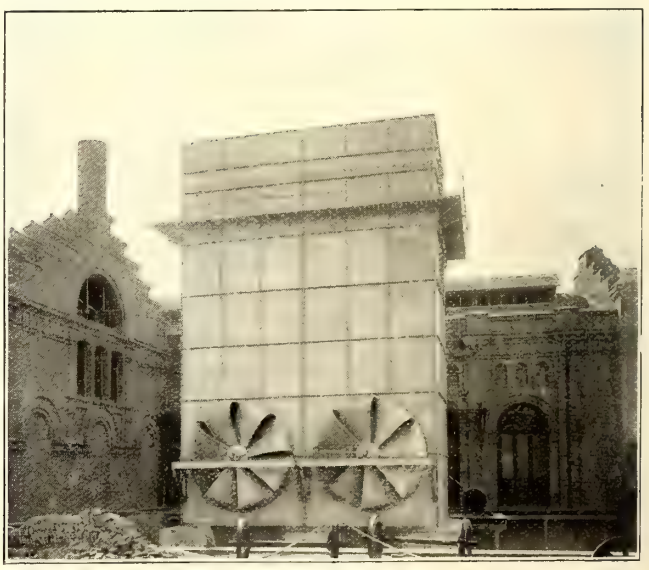
SUPPLY SYSTEM

The overhead construction in both cities is generally of the center pole type, though span wire construction is also employed to a considerable extent. The poles are steel tube, with a length of 26 ft. 6 ins., and taper from 7 ins., at a point 6 ft. above the ground, to $3\frac{1}{2}$ ins. at the top, the butt end of the pole being parallel. The poles are bedded in concrete to a depth of 6 ft., and some of them, especially those in the principal street, are most ornate. The whole of the cast iron work for this was done in Spain, and the manner in which it was executed shows that the Spanish art of manipulating iron has not been lost. The brackets of the center pole construction, as will be noticed, are extremely short, and in most instances are not more than 15 ins. in length, and give a remarkably pleasing and unobtrusive appearance to the over-head work. This result is made possible by the use of the lateral or Dickinson type of trolley, which is employed throughout. A section of the base of this trolley, with the arrangement of springs, is shown in one of the engravings on page 81.

All feeders are laid underground, and the distribution from the generating station is arranged as shown in the accompanying plan. The bitumen solid system has been used throughout, the cables being laid in cast iron troughs, supported on suitable bridges, and the whole then filled in solid with bitumen. Distribution is made in Madrid from under-ground boxes at feeding and section points. This was necessary because the authorities would not allow the ordinary type of feeder pillar to be erected. The engravings show the general arrangement of these boxes, the number of connections varying according to the location.

STANDARD CAR, BARCELONA

In Barcelona railway pillar boxes as shown in the cut are used.

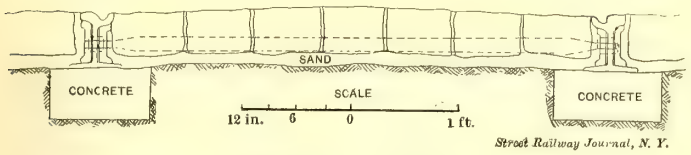


The overhead system is divided into half-mile sections by means of the section insulators, on the same conditions as laid down by the British Board of Trade. The feeder boxes, through which the current is taken from the cables to the line, are supplied with the usual switches and fuses, and, in addition, a pilot wire for testing purposes. This latter wire is also to be used for communicating with the generator station by means of a portable telephone. Where return feeders are employed, and their use is quite general, especially in Barcelona, they are laid in cast iron troughs and bitumen, similar to the outgoing feeders.

VIEW ON THE CALLE ALCALA, MADRID

TRACK CONSTRUCTION

With the electrical equipment of the line the track has been entirely rebuilt and the gage adopted is 4 ft. $8\frac{1}{2}$ ins. The rail is of the grooved type, weighing 82 lbs. per yard, and rests on a stringer 6 ins. deep, and 1 ft. 6 ins. wide, made of concrete in the proportion of one part of cement to five parts of broken stone, gravel and sand. The rails are double bonded at each joint.

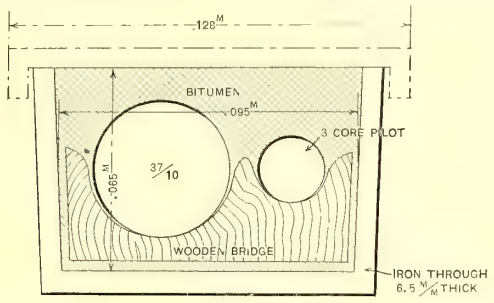


COOLING TOWER, MADRID

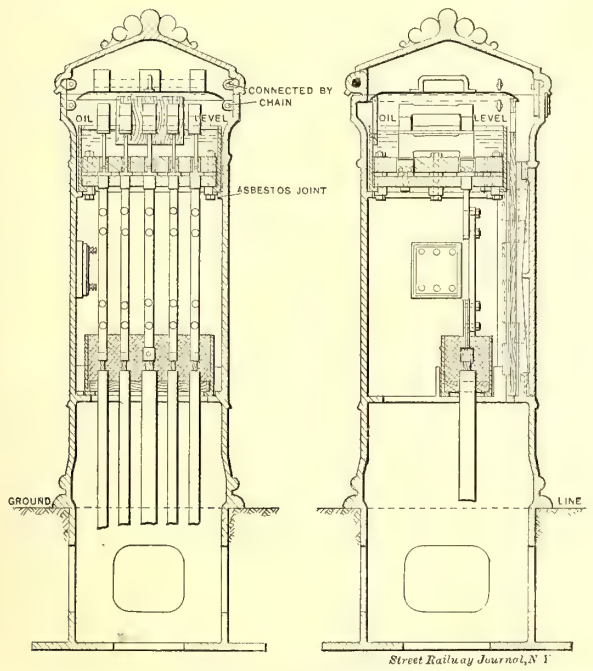
ROLLING STOCK.

The cars in use were built to specifications at Saragossa, and are very similar in general appearance to those used in America; in fact they were modeled on American lines, except that extra large platforms are in use. The cars measure over all 25 ft. 2 ins., with body length, inside, of

15 ft. 9 ins. and width of car 6 ft. 11 ins. They carry forty-four passengers, twenty-two seated and twenty-two standing. Eighty-five cars are in use at Barcelona and fifty-five at Madrid.



The cars are mounted on trucks of the Brill 21 E type,



SECTION OF TRACK

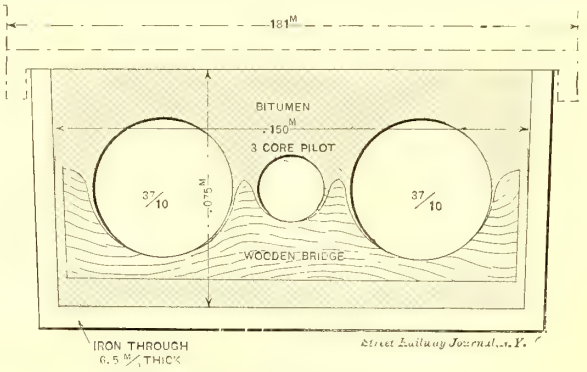
with 30-in. steel wheels with cast centers and rolled steel tires, and are equipped with two motors with series parallel controllers. The trolley is of the Dickinson type, as described elsewhere.

Both plants possess peculiar interest from a tramway standpoint, as they are practically the first examples of the electrical equipment of large continental tramway systems upon strictly American lines, viz., the use of slow-speed,

CONDUIT FOR ONE FEEDER

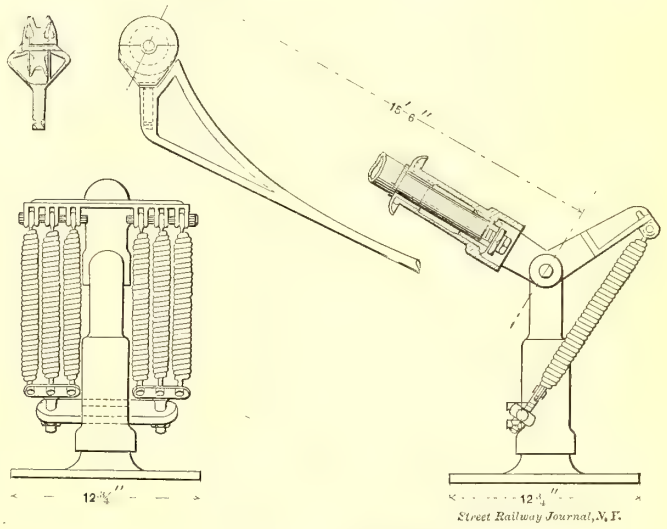
FEEDER PILLAR SWITCH

direct-connected engines with water tube boilers, economizers, single-deck cars, etc. The only important feature in which a departure has been made from standard American practice has been in the use of the Dickinson trolley.



Taking into consideration the extent of these two installations and the circumstances under which they have been made, their successful completion within practically one year from the date of signing of the contract must be regarded as exceedingly creditable both to the consulting engineers, Messrs. Alfred Dickinson & Co., who were responsible for the plans and who supervised the entire installation, and to the contractors, Messrs. Dick, Kerr & Co., Limited, by whose staff the work was carried out without a hitch from beginning to end.

Method of Splicing Cars in Philadelphia



The Union Traction Company of Philadelphia is splicing at its car repair shops quite a number of its old 18-ft. cars, making a new body 25 ft. in length, which is mounted on eight-wheel trucks. In the operation of splicing, the cars are cut in two and the sills are united by a corresponding section inserted with a ship splice, when the whole is reinforced by a steel angle plate 6 ins. x 4 ins. and ⅝ in. in thickness. This is placed on the outside of the sill with the 4-in. limb on the under side. The car is also reinforced by truss rods. The sides and roof are then completed to correspond with the original structure of the car.

An Important Appointment

The Boston Elevated Railway Company has engaged John Lundie, the well-known expert in railroad transportation, as its consulting engineer, for the construction of the new elevated railway in Boston, and Mr. Lundie will shortly begin his preliminary work in laying out and determining the factors in the elevated railway composition as presented by Boston's peculiar conditions. Mr. Lundie's valuable work in analyzing the traffic conditions of the Illinois Central's Chicago suburban lines has given him a high place among railroad experts, and his exceptionally careful study of the Brooklyn elevated railway problems during the past few months has brought him even wider experience. Mr. Lundie's unique methods of attacking railroad transportation questions are the admiration of those who have been privileged to follow them, and his grasp of all the elements entering into any particular case is remarkable.

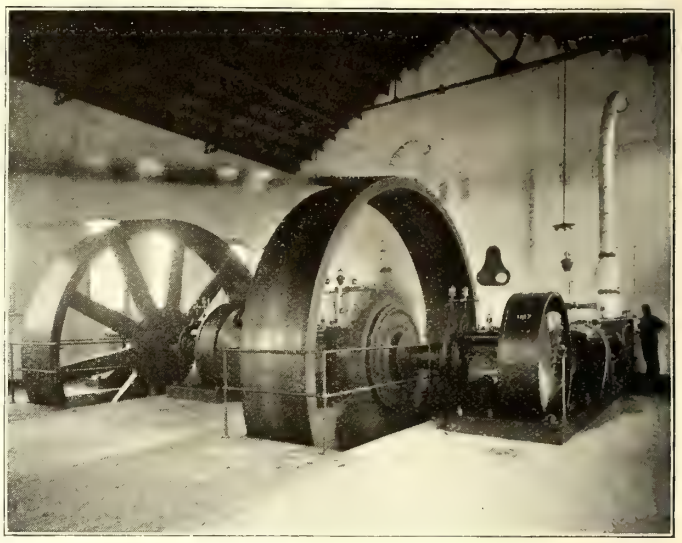
CONDUIT FOR TWO FEEDERS

DETAILS OF TROLLEY

The Cincinnati & Hamilton Electric Street Railway

In Southeastern Ohio there is now completed a system of connecting interurban electric roads reaching from Cincinnati to Eaton via Hamilton and Dayton, a distance of nearly 100 miles. The lines extending from Eaton to Dayton, and from Dayton to Hamilton, were completed a year ago, while the Cincinnati & Hamilton has just been placed in operation. The road is 15 miles long from Hamilton to the point where it connects with the lines of the Cincinnati Street Railway Company.

The company owns its right of way, which lies alongside a highway owned by a corporation, from whom the railway company purchased the right of way strip. The road throughout its entire length has been chosen so as to lie upon the highest ground, and in this way the high water so frequent in the Miami bottoms will be avoided. The route is very rough, there being but few level stretches in it; the maximum grade is 5 per cent and 1,000 ft. long. There are many sharp curves, but they have been laid out with such extreme care that they can be rounded at a high rate of speed.



The brick power house is located at Symns Corner, some 5 miles from the Hamilton end. It is 143 x 49 ft., covered with a slate roof supported on steel trusses and has cement floors. There are installed two Hamilton-Corliss engines of 600 h.p. each and running at 90 r.p.h. The cylinders are 24 x 28 ins., the fly-wheels 20 ft. in diameter and weigh 27 tons each. The engines are belted to 400 kw. Westinghouse generators.

Four Stirling water tube boilers of 250 h.p. each form the boiler equipment. These boilers are the Stirling Company's standard street railway type, provided with large drums affording liberal steam reserve space and disengaging surface, sudden demands for steam are thereby provided for without the usual attendant danger of entrainment or sudden dashes of water into the cylinders of the engines.

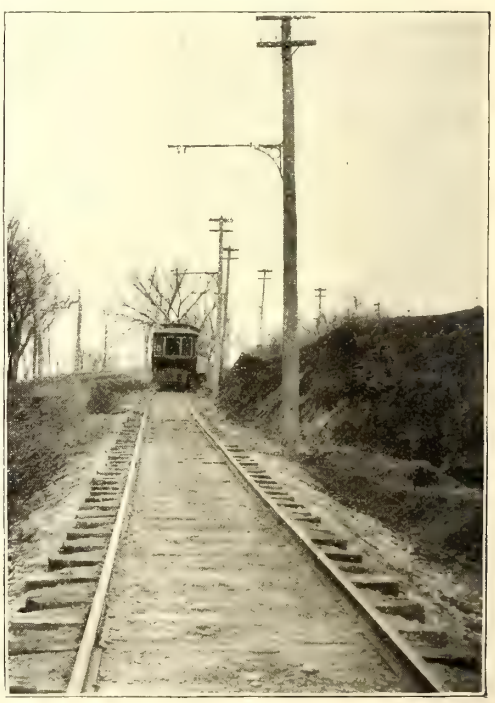
Berryman heaters, Austin separators, Hoppes purifiers and Laidlaw-Dunn-Gordon pumps make up the remainder of the power house equipment.

The furnaces are fitted with two sheet iron stacks 100 ft. high by 5 ft. diameter; these are set on the boiler walls and held in position by two sets of guys. The storage cistern holds 3,000 bbls. and is supplied from two wells 70 ft. deep reaching into the river gravel.

Near the power house is the car barn 152 x 96 ft., with a wing 69 x 41 ft. It is also of brick with a gravel roof.

ENGINES

There is room for twelve cars and the repair department is also under this roof.



Five fire plugs connected with a fire pump in the power house are located in and around the buildings.

Two No. 0000 trolley wires are used. These are hung from brackets on 7 in., 35 ft. cedar poles, except in the towns of Mt. Healthy and College Hill, where iron poles were demanded by the residents. Three cables of 300,000 c.m. feed the southern part of the road, and two of the same size are required for the northern end. All overhead material was furnished by the Ohio Brass Company. The track is double bonded with No. 0000 Washburn and Moen bonds.

The rails are 70 lb. T section laid on oak ties 6 ins. x

VIEW IN BOILER ROOM

BRACKET WORK

8 ins. x 8 ft. At the joints are 6-bolt angle bars. All special work was made by the Lorain Steel Company. A good heavy layer of ballast, consisting of either gravel or broken stone, is used everywhere. The company bought gravel beds near the line and used two steam engines for hauling its gravel trains.

Eight Kuhlman cars constitute the rolling stock; these are 43 ft. long over all and weigh 25 tons. They are

TERMINAL STATION AT COLLEGE HILL

painted maroon and yellow and are substantial, comfortable and elegant, and are mounted on double trucks of the Peckham Truck Company. They have smoking compartments, are heated with the Consolidated Car Heating Company's electric heaters, and fitted with New Haven registers. The motors, controllers, gears, and pinions and the electric brake are all of General Electric design.

The despatching is by the well-known Garl Telephone system; a portable instrument is carried on each car and plug-in stations are located along the line at intervals of 1000 ft. The road was projected and built by Christy Bros., Akron, O. The officers are Will Christy, president; F. J. J. Sloat, general manager. F. H. Conner was in charge of the erection of the plant.

Roadway Department of the Union Traction Company, Philadelphia

The extent of the system of the Union Traction Company, of Philadelphia, the company owning a greater number of miles of track than any other in this country, has permitted the company to introduce certain methods and appliances into its various departments, which, in many cases, could be adopted to advantage by smaller companies. It is the purpose of this article to describe the practice of one department only, that covering the important subject of roadway. The work of this department embraces not only the care of the track and roadbed, but also the care of the conduits for underground cables, the paving of the entire streets on which the tracks are laid, the care of all the bridges on the system, of which they are seventy, all building repairs, including those on the car houses, power houses and the stables for the draft horses, and the feed and care of the horses. The work is carried on under the supervision of H. B. Nichols, with the designated title of engineer of way.

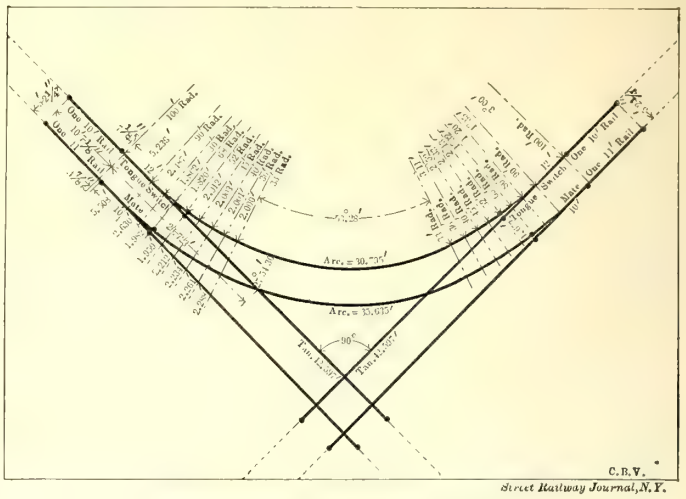
The forces employed are divided into regular and emergency gangs. All orders and assignments for work are issued from the engineer's office to the foremen of the divisions, of which there are three. The regular gangs have a monthly assignment as to the streets to be covered, and detailed orders to them are issued daily. It is the practice to go over the entire trackage once a year for surfacing, examining and tightening joints, as well as for reversing or renewing angle plates, except where the cast-welded joints are employed.

All paving is also inspected once a year by the regular gangs, while the special forces repair any dangerous holes and attend to complaints, replacing any stones that have been forced from their bed, and repairing the asphalt surface where necessary. The different classes of paving are all numbered, and consist of about an equal amount of granite blocks and asphalt, with some brick. Included in the work of the special gangs is the shoring and protection of all excavations for sewer or pipe connections, whether the excavation is made by the company, by the city or by private parties. The expense for shoring, if for the city or for private individuals, is charged up to the persons or body for whom the work is done.

All jobs for repairs, either to track or paving, or for other purposes, are numbered, and all labor and material are charged to such a number. The labor account for each job number is shown on the daily time sheets, which are forwarded every night, by the time keeper of that division, to the general office. In the issuing of material from the stock room, the amount is first temporarily charged to the foreman of each job, and he is also given credit for any scrap or material returned. The amount of material actually used is given on the material slip, which is forwarded to the general office by the store-keeper. When the job is finished, the amount is charged to the number, and the account of the foreman balanced, but he is held responsible for all work and material.

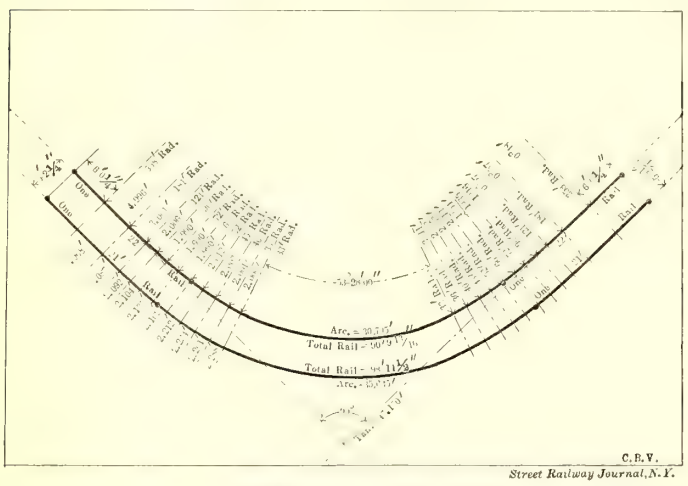
The care of the special work includes the cleaning of switches, sanding the tracks on the hills and oiling the curves. For this purpose, especially designed carts or wagons, to the number of fifteen, are provided and supplied with pails for oil and sand. On the rear of the cart is a step for the driver, so that mounting and dismounting are rendered easy. Each driver is assigned to a certain district, in which he is expected to keep the switches and curves cleaned and oiled, and the hills sanded. The cost of removing snow and ice is not charged up to each street, as in the paving repair, but goes in as a lump sum. The removal of ice from the track in cold weather is quite an item, as in many parts of the city surface drainage is employed, and water from the alleys runs over the rails and freezes in cold weather.

The engineer of way makes a monthly statement to the president and general manager of all work done during the month, under classified headings. At the beginning of each month also he hands in an estimate of the cost of material and labor required for the current month, and also reports the different classes and amount of track supplies on hand. The material in stock is checked up twice a year, and with the careful records kept, the resources and amount of material on hand can always readily be ascertained.



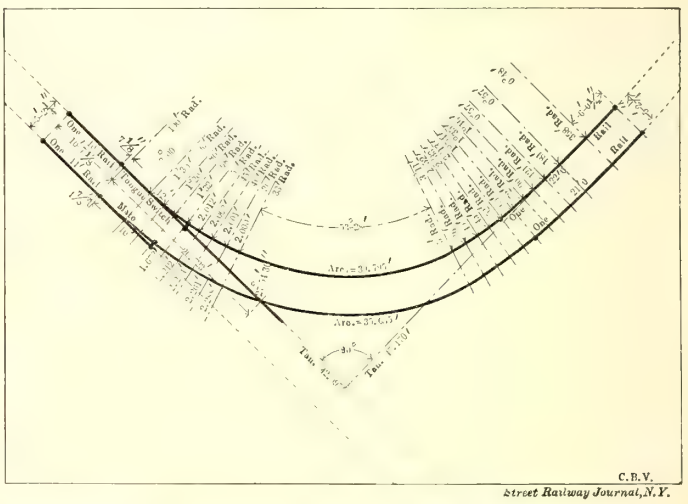
In the consolidation of the various companies into the Union Traction Company the new company inherited a great variety of rail sections, so that the work of keeping the track in repair is very considerable. The cast-welded joint is employed to a large extent on the old rail sections, and about 10,000 such joints are now in service. The standard rail, as required by the city authorities, is a 9-in. girder, but with various head modification. The standard joint plate is 36 ins. long, with twelve bolts. The mileage

also includes about 27 miles of T rail construction on rock ballast. This is the easiest track to keep in repair, and is generally laid on the side of macadam roadway. The company is required to keep in order 35 miles of macadam paving, and for this work a regular force is employed, equipped with steam rollers and other road machines.



All designs for special work are made in the draughting room, under the direction of the engineer. Each piece of special work is numbered and a record is kept of all repairs required on it. A record is also kept on file of the life of each piece.

SPECIAL TRACK



Two standard types of spiral transition switches are employed for all the turnouts on the entire system, one or the other of which installed is depending upon the radius of curve. The accompanying diagrams show the design of these two standards and the cross section at different points, and the table of curves illustrates the method of laying out the spirals. The wearing surface for the switches, frogs and mates is all of manganese steel. In the construction, a very large bolt is employed at the heel of the tongue, and the latter, it will be noted, is reinforced at the base, the sides of the track being under-cut. There are several other special features, including two grooves in the mates, for the wheel flanges, so that with four-wheel trucks the flanges of the front and rear wheel can run in separate grooves. The system requires about 3000

pieces of special work, including steam crossings, of which there are about 135, and the crossings embrace from two to twenty tracks, making about 700 track crossings.

The company manufactures a large portion of its special work, the balance being purchased from the Lorain Steel Company and William Wharton, Jr., & Company. A special shop has been fitted up for track work, and a very complete assortment of tools and appliances have been installed. The track shop occupies a two-story brick building, having a large floor space, and the upper floor, which is served by an elevator, is utilized for setting up and fitting the work; it is the practice to set up complete all curves, crossings and special work, before sending them out. The tool equipment embraces a circular cold saw, operated by an electric motor, heavy punches and shears, a cupola and foundry equipment, two portable hydraulic bending machines, one of 75 tons and the other of 125 tons, both of the Watson & Stillman make. Among these special appliances worthy of note are the beds on which the special work is cast welded. In the preparation of these beds a foundation of concrete, 3½ ft. in depth, is first laid. On the surface of this are steel plates having slots similar to those in the bed plate of the planer, and into these slots are placed the heads of bolts, which serve to anchor the parts

PORTABLE ELECTRIC DRILL

firmly into position. The sand molds are then made around the junction, and into them the molten metal is poured. There is also a second bed with 4-in. T rails, between and beneath the heads of which the anchor bolts are slid. On the opposite side of the shop is a surfacing bed, consisting of a perfectly level wooden floor, reinforced by strips of steel plate ¼ in. in thickness and 3 ins. wide, spaced about 18 ins. apart. By placing rails or special work on this bed, any unevenness in the surface is readily detected. For cast welding simple joints, or where it is necessary to connect rails of different patterns, a mould, consisting of adjustable pieces called chills, is employed, and so designed as to be readily clamped into place. For this class of casting a specially prepared bed is employed. It is in the yard adjoining the shops, and is protected by a temporary cover. In addition to the joint castings and special work the foundry department supplies drain grates and almost all kinds of castings required in this department. The cupola blast is generated by a rotary blower driven by an electric motor. The cold saw mentioned above is also driven by an electric motor, which is started by an ordinary type K controller, but with a water rheostat in place of the ordinary resistance coils. This rheostat is home-made, and consists of a large cask located on the floor above. It is filled with water, in which are two large plates of iron, to which the conductor terminals are attached. To one of these plates is fixed a wooden bar which works in a guide, and is designed to lift the top plate up or to let it down. This bar is operated by means of a rope and windlass from the floor below adjoining the saw. In this way the speed of the saw is readily changed by the windlass rather than the controller. The rails are fed to the saw by a peculiarly designed trolley hoist. The track for the hoist consists of an I beam, about 30 ft. in length, with one end pivoted above and just to one side of the line of the saw bed. The other end of this beam is fitted with wheels which are operated with a hand

PORTABLE EMERY WHEEL

chain, so that it can be swung around on a circular track. This provides a wide range for the hoist, so that pieces of rail may be lifted and readily conveyed to the saw, and in case of a crooked rail, the outer end of the rail can be supported in any position.

For drilling rails, either in the shop or on the line, the company uses a portable electric drill, illustrated on this page. This drill consists of a box or case having two wheels and handles like those of a wheel barrow, on which is placed a 2-h.p. electric motor; the latter is provided with a Stow flexible shaft through which power is transmitted to the drill, which is clamped to the rail in the usual manner. By this arrangement, holes for tie rods, or for other purposes, can be readily drilled. For delivering the current to the motor a pole with a hook to which an insulated conductor is attached, is used. The end of this pole can be hooked over the trolley wire anywhere on the line, while the return circuit is provided by the rail. Another motor similarly mounted and provided with a flexible shaft is employed to operate an emery wheel used for grinding the surface of the rails where the cast-welded joint is employed. The emery wheel is mounted on a short shaft with insulated handles on each side, consisting of thimbles surrounding the shaft. The operator holds the wheel in position by means of the handles, and it is readily adjusted to any surface. A portable motor is also employed for operating a hack saw, so that the rails may be cut at any place on the line. This saw is connected to the rails by means of a frame and clamp, and is capable of sawing a 9-in. rail in nineteen minutes. In connection with the track work there is an auxiliary shop furnished with a number of small iron working tools on which machine repairs are made, and where, also, such small tools and dies as may be required are manufactured.

The track shop is in charge of H. H. Nichols, who has held the position of foreman about two years.

W. D. Young, electrical engineer of the Baltimore & Ohio Railroad Company, writes that that company has not decided to instal the third rail system in the Belt Line tunnel, but has simply been looking into the advisability of its adoption in place of the present overhead structure.

Wrinkles in the Hartford Street Railway Company's System

The thought expended on the little labor-saving devices around a street railway is the best evidence of success, for the successful railway management is a problem of details satisfactorily solved. The Hartford Street Railway Company has introduced many wrinkles, and the following have been selected as being general useful pointers to any system. Mr. Crawford, the general manager, and Mr. Caum, the chief engineer, are responsible for them.

A method of always obtaining dry sand without the cost of drying is an attractive proposition. In Hartford the problem has been solved in this way: Over the boiler room a sealed loft has been built that is used to heat the barn and repair shops. Fig. 1 shows the side elevation of the loft and boiler room. It will be seen that the iron stack from the boiler down stairs passes through this room, and around it is a wrought-iron funnel with a circular opening about 2 ins. wide around the stack at the bottom, and with a flare about 2 ft. wide at the top. The wet sand is introduced into this hopper by a conveyor from the sand pile. This conveyor is run by a motor. The sand when dried by the heat of the stack spreads over the flue of the sand bin, and is perfectly dry by the time it reaches the spout,

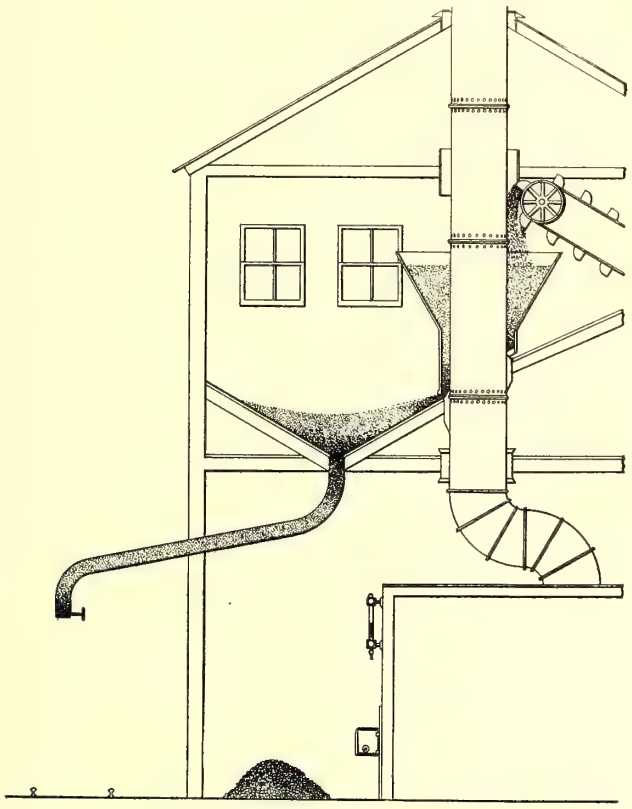

FIG. 1.—METHOD OF DRYING SAND

whence it is delivered into the sand car. In this way the sand is dried practically automatically, and by a heat that would otherwise be wasted.

Eventually Mr. Caum proposes to fill his car sand boxes with sand by a rather novel method. It is not generally known that sand, under air pressure, will flow through a pipe for several hundred feet like a viscous fluid. The pipe itself, however, should curve to changes of direction, and sharp corners with the regular pipe fittings should be avoided. A flexible hose can be used with a valve at the end. This hose can be carried into the car and the sand box filled without the dust and spilling of sand which usually accompanies the replenishing of sand boxes.

The use of the car rheostatic controller, which operates by moving the handle to the right to go forward, and to the left to reverse, leads to accidents. Where a motorman is required at times to operate also a series parallel controller, with a separate reverse, he is liable to move the handle of the controller past the neutral point and reverse the motors in the rheostatic controllers, as this action is just like that of the series parallel controller in passing from multiple to series. Several accidents being attributed to this cause, the Hartford people filed a square hole in the cover of the controller, and into this fitted a metallic block, which projects through far enough to strike the handle when in open position. In this way the motors are protected from being reversed by mistake. A view of the controller with this device is shown in Fig. 2.

Car houses are hard places to keep warm, largely on account of the warping and poor fitting of the doors to their jams. In Hartford a special device is used to draw the door tight, and it is made by the company's blacksmith. The door is swung on the outside, and a long strap-iron U is fastened to the top of the door, as shown at *A*, Fig. 3. The

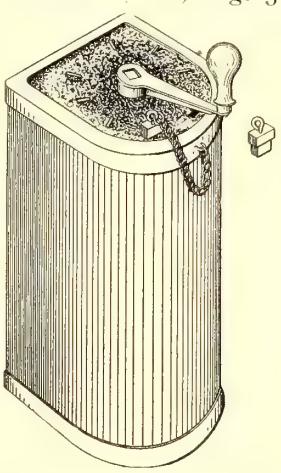

FIG. 2.—CONTROLLER CATCH

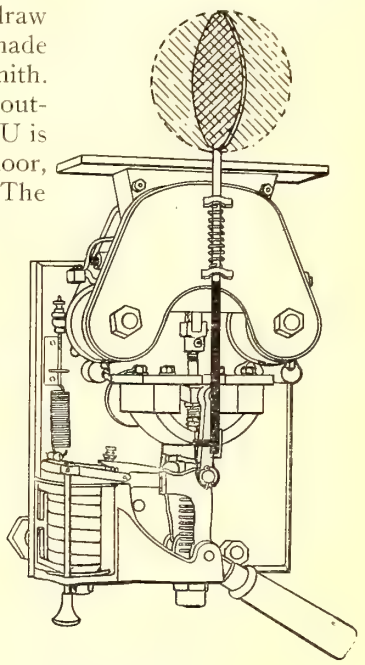

FIG. 4.—CIRCUIT BREAKER SEMAPHORE

wedge-shaped latch is operated by two levers from the barn floor, and is forced into this U, drawing the door tight up to the jam. The result is that the car house can be easily warmed.

Where there are a number of circuit breakers in a row on the switchboard it is difficult at a distance to see which one is open. The Hartford Company has a long narrow power house, and the station engineers have devised a semaphore system to clearly indicate what circuit breakers are thrown. The arrangement is as follows: The toggle joint in opening up the switch jaws strikes a pin, which gives a quarter turn to the semaphore on the circuit breaker and displays a red disc. This is invisible from the engine room floor when the circuit breaker is closed, for it is then edgewise. Each generator circuit breaker is also provided with a semaphore, so that the engineer at a glance can see which units are operating on the system. Fig. 4 shows the general arrangement.

The oiling of a bearing by the oil-can method entails both a waste of oil and manual labor. The conduction of oil to the bearing by a piping system and its withdrawal again after it has worked through the bearing surface the lubrication can be made automatic in its action and does not require the handling of the oil. Mr. Caum has developed for the Hartford Street Railway power station a very complete system.

Each engine has an independent piping system, which can be shut down with the engine; all piping systems are controlled from one point, and a sight feed is introduced into each pipe line. The oil is fed from supplementary tanks in the engine room to the engine bearings by gravity. A tripe valve is used, so that air can be blown through the pipe to clean it out. Five-eighths-in. brass tubing and brass fittings are used throughout. The oiling system can be fed from two independent sources of supply.

The oil house is located at a distance in the rear of the station, and is divided into three fire-proof compartments, which are lighted externally by lamps placed outside the windows. One compartment is for the handling and storage of cylinder oil; another contains the filters, and a third cooling and storage tanks. The oil from the bearings

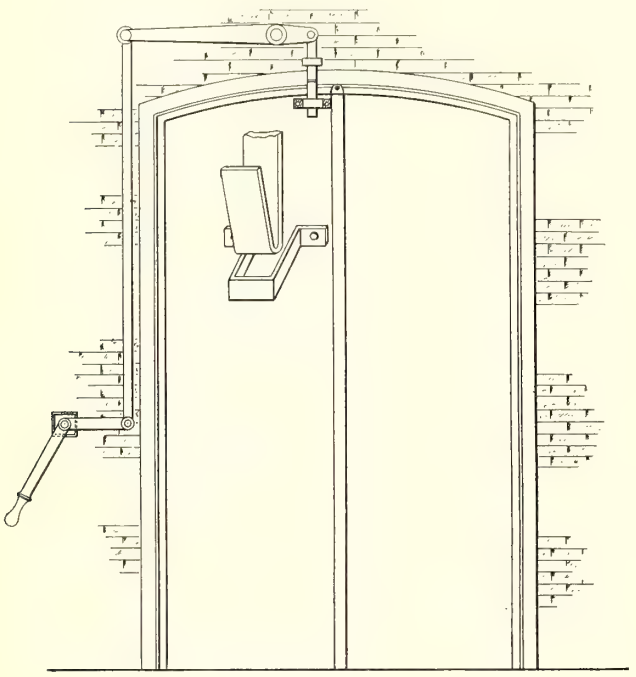

FIG. 3.—CAR HOUSE DOOR CATCH

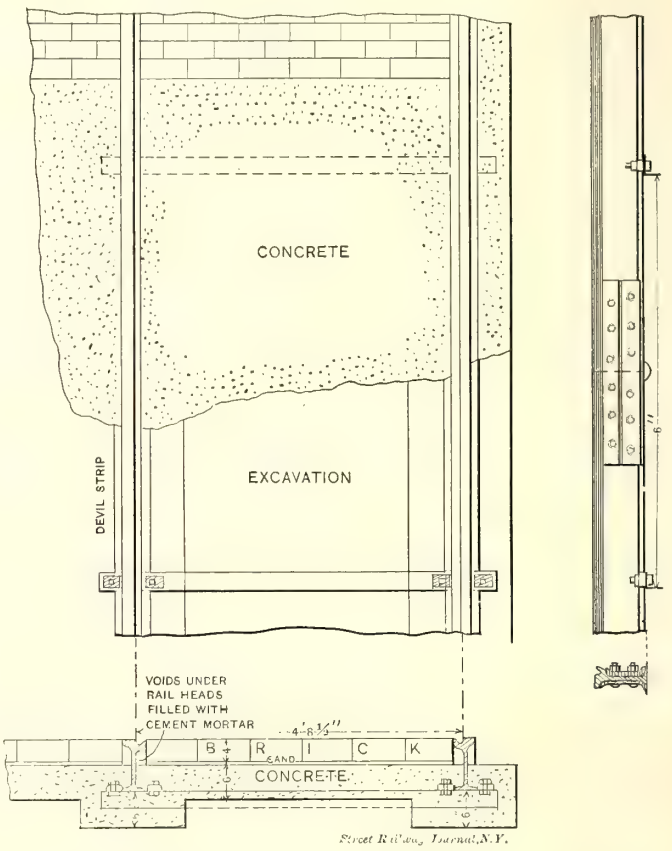


collects in a receiving tank and is forced from this by compressed air to the filtering room, where it is heated and run through filters. From the latter it is forced to the cooling and storage rooms.

There is a duplicate system both in the oil house and up to the air compressor. By turning a two-way valve either supply can be drawn on. The rate of flow of oil through the bearing is about a gallon in two minutes. It is found that the oil does not get worn out as fast when circulated rapidly, and the volume has a cooling effect on a bearing which tends to heat.

The method used for supplying a bearing with oil and drawing it away is accomplished without the slightest external appearance of oil. The engines supplied are horizontal, and the wipers on the crank-pin and the crosshead pin have been dispensed with. The crankhead is lubricated by means of holes drilled at an angle through the cranks from the circumference of the main bearings to the crank-pins. Holes are drilled from the top of the crosshead to the crosshead pin and through the latter to the bearing. This receives oil furnished to the top guides. There is no indication of oil on the white floors and the amount of oil required to supply the waste is extremely low. Even the self-oiling bearings of the dynamos are piped up and supplied with oil by this circulating method, to furnish fresh cold oil during extremely hot weather.

Track Construction on Concrete in Detroit

The Detroit railways were among the earliest in this country to employ concrete for sub-construction in street railway track. The original construction employed by the Detroit Citizens' Railway was a 9-in., 100-lb. grooved rail carried on steel ties spaced 5 ft. centers. The ties were channels 7 in. wide x 7 ft. long and $\frac{3}{8}$ in. thick, with a flange of $1\frac{1}{8}$ ins. deep. They weighed 21 lbs. each. The concrete was laid 6 ins. below the base of the rail and tamped under the ties. It was also laid on top of the ties and carried up

PRESENT STANDARD TRACK CONSTRUCTION IN DETROIT

to within $1\frac{1}{2}$ ins. of the base of the paving. When Belgian paving was used, the latter was then laid on $1\frac{1}{2}$ ins. of sand. The same construction was used with asphalt.

The Detroit Railway, which was built about the same time, used in part wooden ties and in part concrete stringers. The wooden ties were laid on a 6-in. concrete base, between which and the tie was a 1-in. layer of sand. Concrete was also carried up above the ties, and where 5-in. paving was used with a 7-in. rail, the concrete extended to a height of $1\frac{1}{2}$ ins. above the ties. There was then a layer of $\frac{1}{2}$ in. of sand, on which the paving blocks rested. Where concrete stringers were used a trench was first cut 15 ins. deep and 1 ft. wide, a layer of concrete composed of one part of Portland cement, four parts of Louisville cement, eight parts sand and sixteen parts of broken stone, was laid in the bottom of the trench to a depth of 6 ins. The rail, which was 7 ins. high, was then placed in the trench and the 2-in. space between the top of the concrete and the bottom of the rail, with the space on each side, was filled up to the bottom of the pavement with grouting, composed of one part Portland cement, one part sand and three parts of clean fine gravel. The rails were bound together with tie rods placed 10 ft. apart.

The two railways are now under the same management, and the experience of the last three years with both types of track construction have

led to some slight modifications. The stringer construction of the Detroit Railway was found to have gone in spots, and it was thought that this was due in part to the method of holding the rail, which, being with tie rods, did not hold the rail vertical. On the other hand, the heavy ties employed on the Citizens' Railway were not found necessary. The accompanying engraving shows the standard type of track construction now employed by both companies. The present tie is a 3-in. angle bar, and its use is more for keeping the track to gage and the rails vertical, for which purpose it answers better than a tie rod, than it is to support the rails. The concrete is carried down 6 ins. below the base of the rail and covers the ties to a height within half an inch of the base of the paving, which in the engraving is 4 ins. thick. If, however, there should be any soft spots encountered in laying the track the concrete is carried to a greater depth, 2 ft. if necessary, to give a perfectly substantial base for the rail. The management consider the construction illustrated perfectly satisfactory with the clay sub-soil, but with a sand sub-soil would not recommend any type of concrete construction.

After the concrete is laid it is necessary to let it set for five days without running any cars over it if the weather is dry; in the fall when the road is moist it sometimes must be allowed to rest a week. Over 98 miles of track have been constructed in this way during the last three years. The rails are bonded with a U-shaped riveted bond in the base of the rail. The rails are not cross connected, as the axles are depended upon for this purpose, but the inside rails of the double-track are cross connected for 500 ft. by Chicago rail bonds.

As is well known, the Detroit Railway Company installed a considerable amount of electrically welded rail on its Jefferson Avenue line. This rail is still in good condition, and is satisfactory, although the company is not electrically welding any more of its track rails. One chief advantage found with the electrical weld was the good electrical return which it afforded, and the section welded is that upon which the power station is located, so that these rails afford an excellent return to this point, in fact so good that no ground return is employed. In all, about 2 per cent of the welds have broken during the past two years. Where this has occurred the rails have been well bonded.

Changes in Brooklyn

Official announcement has been made that the controlling interest in the capital stock of the Nassau Electric Railroad Company has been purchased by the Brooklyn Rapid Transit Company, owner of the Brooklyn Heights railroad and the two roads will hereafter be operated in complete harmony. The Nassau Company has $6,000,000 capital stock outstanding, and $4,849,000 bonds, and was formed for the purpose of operating the Atlantic Avenue railroad and the Brooklyn, Bath & West End Railroad.

It is stated that very few changes will be made at present in the actual operation of either of the companies with the exception that one or two of the Nassau lines will be given a through service to New York via the bridge over Brooklyn Rapid Transit lines. A number of changes in the personnel of the Nassau Company has been made, however, and the present officers and directors are as follows: President, John E. Borne; vice-president, Hugh J. Grant; treasurer, C. D. Meneely; secretary, W. F. Ham. The stockholders of the Brooklyn Rapid Transit Company will shortly vote on the proposition to increase the capital stock of that company to $45,000,000.

LETTERS AND HINTS FROM PRACTICAL MEN

Notes on the Standard Rules and Regulations as reported by the A. S. R. A. Committee

SCHENECTADY RAILWAY COMPANY.

SCHENECTADY, Jan. 14, 1899.

EDITORS STREET RAILWAY JOURNAL:

The report of the committee appointed by the American Street Railway Association has now been publicly printed in your columns, December, 1898, and it is, therefore, open to discussion and criticism.

The intrinsic value of a comprehensive, consistent and equitable set of standard rules would be immeasurable. The accepted usages of a road, of similar roads or groups of roads are the "constitution" of discipline, the rules and regulations are its "by-laws." With good rules intelligently enforced, the employees will be bound into a homogeneous and interdependent body, but with rules that are incomplete, inconsistent or inequitable their enforcement will be a subversion instead of a conservation of discipline.

Beyond their application to the employees there is at present a further use of good rules, and that is their effect on the courts, the municipal and other authorities and the general public. In these days of conventions with open doors, unlimited discussions and publications, of yellow journalism which probes and exploits the inmost recesses of everything, of suits at law during which matters pertinent and unpertinent are "expert-ed" and spread broad among the people, in these days, the rules of a company and the measure and quality of their enforcement are very often matters in which the courts, the authorities and the people at large take a keen interest, an interest the results of which are often felt in unexpected ways. There is, therefore, all the more reason that the rules themselves should be as perfect as experience, observation, knowledge—and a desire for perfection—can make them. The enforcing of them is an important, but secondary matter; good rules will partly enforce themselves, but the task of enforcing rules that are unreasonable, unjust, inconsistent or otherwise imperfect, is an impossible one, and if persisted in may become a two-edged sword to be used against the enforcer.

The task given the committee was a difficult and thankless one, difficult, because in a territory so large as that covered by the national association, conditions of every kind vary so greatly that a rule that would be perfectly just, proper and appropriate in one section of the country, *might*, in another section, be considered very undesirable. Also at present, the varying laws, regulations, ordinances, recommendations, etc., etc., of the legislatures, courts, municipalities and railway commissioners of the several States and Territories would militate against the formation of a general set of rules; that is to say, of a set of rules which—without change of form or meaning—should be applicable to all railways in the United States.

The task was a thankless one, because, if there is one thing that the average superintendent or general manager believes to be perfect and immaculate it is his rules and regulations, and he usually does not take kindly to, and is not grateful for any rules which have not emanated from him directly or in the formation of which he has not had a hand, especially if he sees that in many respects they are not actually a betterment. In this he is somewhat right, as his rules are generally the outcome of local experiences and necesities, and while they are often crude and strongly tinged with local color and personal idiosyncracies, they have been, as a whole, more just, wise, safe and reasonable

than those forced—or sought to be forced—on him by local legislators and muncipalities or by the aspiring, but inexperienced directors of his own company.

Moreover, given that the committee had reported an absolutely perfect and complete set of general rules, the Association has no authority to enforce their use, nor has it the means to obtain or compel such authority. It would have to depend on the willingness of each railway that was a member of the A. S. R. A., and of the many who are not, and would have been met at once with the inertia of conservatism and the literary jealousy of every-superintendent-his-own-author.

It seems, therefore, that the A. S. R. A. has given the gentlemen of the committee a doubly difficult and thankless task, as it is well nigh a useless one, and it will not be exaggeration to say that not one company will change its rules to conform to those of the committee at the present time, nor would one in a hundred do so were the Association to ratify and recommend them. This, the Association should have thought of at the time of appointment of the committee, as they have placed the gentlemen of the committee in a very difficult position, and have led the street railways of the country to expect something that cannot be realized. The name itself is misleading even were the thing itself possible, as a set of rules for voluntary use by any and all railroads in the country might be called "Uniform," or "Universal," or "General," but could hardly be called "Standard" unless their use was in some way obligatory.

If the A. S. R. A. had been less ambitious or more thoughtful and had contented itself with asking its committee to prepare a *uniform* set of *general* rules for submission to the several State associations for action, the task of the committee would not have been so out of proportion to its report—and its thanks.

As a matter of fact, the State associations are, at present, the only bodies that should attempt to standardize rules. They represent at once the largest and smallest division or group of street railways that have mutual and uniform interest as regards legislation, and they are the only bodies that possess—even indirectly—mandatory powers, as they can, if their majority wills it, influence and cooperate with their several State Railroad Commissions in the formation and enforcement of a standard set of rules.

Such a standard set of rules would, at present, be of very great value within a State. Ratified by the State association, recommended by the State Railroad Commissioners and enforced by the State legislature, they would have the effect of laws, would greatly simplify lawsuits arising from their enforcement or their neglect, and in cases where they were strictly adhered to would greatly minimize the damages. They would make a more efficient body of the railway employees affected by them, as these employees would be more "standard" as regards general rules and would not have—as now—to change all their ideas and methods because they changed their location and employer. They would greatly lessen difficulties, arguments and misunderstandings with the general public, as the rules would soon become as well understood as the "five-cent fare" and, having the authority of the State at their back, would be much less liable to infraction on the part of the public.

As the State associations and State railroad commissioners multiply, these rules—amplified and amended to meet larger and more general conditions—could be made uniform between State and State until they become uniform and standard all over the country. This is not a millenial forecast, nor a utopian dream, but a matter that is right upon us and needs recognition. With interurban street railways stretching out until they become inter-State, with companies operating roads that run across State-lines, and, perhaps, across States, it is ridiculous to think that the running across an imaginary line on the ground should change the whole character of an employee's actions.

Going back to the committee's report and taking into consideration all the difficulties in their way, it *was* possible for them to have given the Association a general set of rules that could have been offered to the State associations. Underlying all street railway transportation business, from Maine to Texas, from California to New Jersey, are certain fundamental principles which must be followed by *all* if the public is to be served with safety, convenience, comfort, regularity and punctuality, if employees are to serve with the greatest efficiency and with the least danger, deprivation, exposure and labor, if the employer is to obtain a fair profit on his investment and without needless risk. To expound and explain these principles, to apply them to specific cases, to show their capabilities and their limitations, to embody the whole thing in a clear, concise and consistent form—that is the province of a "general" set of rules and regulations.

Such rules *must*

1. Be *rules*, not suggestions nor advice; such—if pertinent—may be prefixed as an introduction or deduced as corollaries, but must not be masqueraded as rules.

2. Be "general" in the sense that they are applicable without change of intent or principle to all street railways or surface railways within the territory they are intended to cover.

3. Be "general" in the sense that they must contain nothing local or individual, either as regards locality or personality, use or manufacture.

4. Be comprehensive, covering every point in regard to all employees whose duties are in any way in connection with the public—either directly or through their fellow employees.

5. Be perfectly clear and lucid in language, admitting of no double meaning nor obscurity of meaning.

6. Be perfectly free from contradictions either within themselves or with one another.

7. Be in acordance with general usage, experience and observation.

8. Be reasonable.

9. Be just and equitable.

Such rules *should*

10. Be couched in plain, simple, terse language so as to be easily understood, and—if necessary—memorized. Slovenly composition, ungrammatical language, false syntax, obscure expression, involved, complicated and inverted sentences are to be as much avoided as "elegant phraseology."

11. Be arranged in some connected, definite and consecutive manner, and divided into groups having specific relation to certain persons, duties, acts or things. Under each group the rules themselves should be arranged as much as possible in a natural sequence or order, all cognate matters should be brought under one rule if possible, and each rule should be preceded by its subject as a heading. On the other hand, no rule should treat of more than one subject.

12. Be free from repetitions either within themselves or of one another. Repetitions *in* rules and *of* rules do not emphasize; they only weaken. Emphasis should be used only in proportion to the importance of the subject and should be manifested by other means.

13. Be free from unnecessary, irrelevant or axiomatic remarks and directions. Employees for whom these rules

are made must be considered as having ordinary common and moral sense; a street railway is neither a kindergarten nor a Sunday-school.

They should *not*

14. Be unnecessarily peremptory in tone; "must" and "shall" used too frequently lose their force. It is much better on ordinary occasions to say "will" and "should." The imperatives should be reserved for imperative cases.

15. Be addressed to the second person—"you." It sounds—and is—better to address the rules to employees in the abstract, i. e., impersonally, and for this the "third person"—"he" or "they" is necessary. This is somewhat a matter of opinion, however, but there can be only one opinion on the question of sticking to one kind of address in the rules, either "you" or "he" and "they" may be used, but they should not be mixed. In an *introduction* to the rules the less formal style is an advantage, as each individual employee is there being addressed, while in the *rules* the employees as a class or group are being instructed.

16. Threaten. Penalties should form no part of a rule, although they may be an adjunct of the rules. Dismissal for certain specific and proven grave offences, such as drunkenness on duty, lying, dishonesty and wilful disobedience of safety rules, should be made a *rule*, but beyond that, all penalties, punishments and threats had better be kept out of the rules and the "punishment made to fit the crime"—when the crime occurs. Prompt and just punishment in actual practice is all that is necessary, and a few cases of such will do more good than a rule-book full of "bogy-man" threats, very few of which can be carried out in practice.

The above qualifications and conditions contain nothing but what is reasonable and necessary in a matter so important, and it will do the report of the committee no injustice to test it by them and see how near it comes to fulfilling them. This will be done in a future article.

H. S. Cooper.

Methods of Accounting

Binghamton Railway Company,
Binghamton, N. Y., January, 10, 1899.

Editors Street Railway Journal:

I notice your editorial in the January issue, wherein you ask for views upon Mr. Kittredge's article entitled, "An Ideal System of Street Railway Accounts," and would say that the system of dividing and sub-dividing of the accounts as outlined are almost identical with those followed in this company, and the ideas expressed by Mr. Kittredge as to intelligent and perpetual comparisons have been carried on by us for several years, for the constant information of the general manager of the company.

In addition to our ledger showings we have a comparative table (special) book, in which we show a constant comparison of the receipts from each passenger division of the road, from various other resources, the operating expenses in detail, as well as increase and decrease in supplies on hand, floating debt, etc., and a daily comparison of each division's receipts. From this statement the management is enabled to watch the earning capacity of each division of the road, and to decide as to what service such division is entitled, also to determine at a glance whether any leakage occurs in operating expenses and to correct such intelligently. The many other details of information conveyed by this table furnishes to the office at all times the exact standing of the road. I mention this book as giving the same information constantly as by Mr. Kittredge's system without what seems to me a complication of bookkeeping.

More as a matter of asking information than criticism, I wish to express the following: The appearance of the Maintenance and Emergencies (sub-divided) accounts in the Reserves, as Liabilities in the Balance Sheet, as I understand it from the article, act as sinking funds for the pro rating and equalizing of all expense accounts.

If this interpretation be a true one, I am at a loss to understand how these accounts could be intelligently pro rated unless an estimate be based in each case upon the year preceding, and even then the variation of a year might be so great that the following year would be unjustly pro rated. While the distribution of expense in the various accounts through different months or shorter periods, might seem just when one thinks of a large expense of replacement falling on one month the expense of which has really been accrued during preceding months, the question arises, how can the pro rating be properly adjusted, and why is not the actual condition of the expense account of more instant and valuable information to the manager than the study of the balance sheet. For instance, would the showing of the same operating expense for the summer months with increased car service for pleasure rides, etc., be correct as against the winter months, or could the removal of snow and ice be pro rated throughout the summer intelligently, and, in that line, would not an open winter, without storms, or a winter with frequent and heavy storms, make an unjust showing of one year with another? Again, how can a company depend upon the life of a generator and, as they run year after year without repair or replacement, have you not created a false asset which must also appear in the balance sheet, or, without indemnity insurance, how can one intelligently pro rate against accidents?

Perhaps I may be speaking from ignorance or a too limited knowledge of Mr. Kittredge's ideas in this respect, but it would almost seem that the receipts could be even more accurately pro rated, thus enabling the accountant to forecast correctly any report, for any time, the other necessary and valuable information being available only to those who have access to the balance sheets.

From a personal point of view, gathered from the information desired by, and on hand for, our General Manager, it would seem that the supply store system with its *daily* charges and vouchers, together with comparative tables, made up constantly from the ledger, properly divided, gives the actual and satisfactory status of the road at all times, which cannot be furnished more acceptably to management, bond and stock-holders, the public, and the State.

John B. Rogers, Treasurer.

Fitchburg & Leominster Street Railway Company,
Fitchburg, Mass., Jan. 9, 1899.

Editors Street Railway Journal:

I have carefully read Mr. Kittredge's paper on "An Ideal System of Street Railway Accounts," and, in general, can commend it very highly.

It must be remembered that small roads cannot go into the detail of classification or of accounting as deeply as can the larger, and there are a great many small roads. There is a danger line beyond which the expenses of accounting are entirely out of proportion with the income and needs of the corporation. For example, with a road of $75,000 yearly operating expenses, a weekly inventory would be an absurd proposition. The expense of it would be en-

tirely incommensurate with the cost of supplies not going into immediate consumption. Yet it is as necessary for these small roads to have a sound accounting system as the largest. So any "ideal" system of accounts must be sufficiently elastic to be of use to all without too great expense to any. This, it seems to me, is a virtue of the system which Mr. Kittredge suggests.

I think Mr. Kittredge's reasoning in omitting accounts *N* and *O* entirely wrong. If the items of these accounts may be classified as assets, as parts of other accounts, why are they not assets "in themselves?" They are more tangible and more properly classified as assets than goodwill, which is almost illusory, and they are as properly separate as accounts *A* and *B*. These latter accounts could be as easily pro-rated among the others as *N* and *O*. The object of accounting must be accuracy, and pro-rating these accounts is far from that, as actual experience shows.

One thing which Mr. Kittredge neglects is tickets. These little pieces of paper do a big business on many roads, thousands of dollars worth of them sometimes outstanding. They are essentially a liability and must be accounted as such. The practice of carrying receipts for tickets sold directly to revenue is wrong. The minute they are sold they become a liability against the corporation and so remain until used.

Further, it seems to me that the classification of dividends declared and unpaid as a floating liability and taxes and interest as reserve accounts is wrong. These are all *accrued* liabilities, and, as such, should have separate classification. Reserve accounts for sinking, maintenance or emergency funds are in no sense accrued liabilties nor are accrued liabilties, by nature, exactly similar to funds for the payment of outstanding liabilities like bonds or future extraordinary expenditures for maintenance and emergencies.

Why are not express and advertising (in cars) receipts from operation as much as freight or mail?

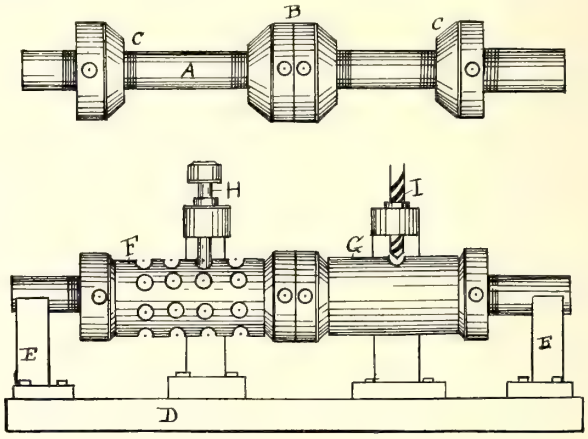
Robert N. Wallis, Treasurer.

Bergen County Traction Company, N. J.,
Fort Lee, N. J., January 14, 1899.

Editors Street Railway Journal:

The form you give in your January issue (chart of Analysis and Classification of Street Railway Accounts) is practically the same we use for balance sheet.

William N. Barrows, Secretary.



Method of Drilling Armature Bushings

Boston, January 12, 1898.

Editors Street Railway Journal:

They have a way at the West End railway shops here for drilling street railway car axle bushings that is both simple and effective. The rig is especially designed for drilling plug holes in the bushings. A double-end arbor is used, with a drilled bushing on one end and a bushing to be drilled on the other end, as shown in the annexed sketch of the tool.

The arbor (A) is cut with a thread and movable nuts (B) and (C) put on. These nuts are cone-shaped on the sides facing in, and are screwed up on the bushings, as shown in the next view, which represents the bushing (G) in process of being drilled to correspond to the master bushing (F). The arbor rests in the bearings (E) (E), and can be turned easily by the hand. The guide pin (H) rides in the shoulder piece, and the latter is set-screwed to the base piece (D). The drill (I) operates in a leader, which is set-screwed to the base. The nuts for sustaining the bushings in place can be square and tightened with a wrench, or they can be round and provided with holes in which to insert a shaft for turning. As the nuts hold the bushings very firmly in place the machinist can be sure of getting uniformly drilled work. Bolt holes, etc., may be drilled at regular intervals in other lines of work on this device, and at any desired distance from the axis and from

TOOL FOR DRILLING ARMATURE BUSHINGS

each other, regardless of the diameter of the pieces or the length. The jig can be provided with an index plate that can be set for any number of equal divisions and clamped firmly in position. The drill is held in the usual manner, and by means of a variety of sleeves this jig is ready to drill equal spaced holes at the proper distance from centers.

B. F. F.

Amusing Letters

Nearly every railway manager has received letters more or less amusing, asking for a position, damages for a supposed injury to property or feelings, or protesting against some "outrageous" invasion of the author's rights. Below will be found a copy of a letter recently received by F. J. J. Sloat, of the Cincinnati & Hamilton Railway Company.

Hamilton, Ohio, Dec. 19, 1898.

Mr. Sloat and Will. Christie:

Dear Sirs.—The 13 of this Month the No. ten Car Cut My valuabel Dog In Two you have no Pitty for Me I Am Lonesome For My Dog yet I was ofered A Big Prise For My Pet Dog I Would not Take it I would rather have My Dog now What will I do and What will you do My dear Dog is gone.

Yours Most Respectfully,

Mrs. ——— ———.

P. S.—Mr. Sloat Swope has fine dogs get him to give me one In Return For Mine Mr. Sloat you know I Deserve A good Dog.

Mrs. ——— ———.

Great as the loss of her dog must have been to this lady, it was insignificant as compared to the damage recently inflicted upon a gentleman in Brisbane, Australia. His pathetic letter to J. S. Badger, manager of the Brisbane Tramways Company, describing the catastrophe is given below, and should act as a warning to all those who persist in sitting on the hand railing on the top of a double-deck car while escorting ladies home from the theater.

To the Manager of the Brisbane Tramways Company, Ltd.:

Dear Sir.— I regret to have to inform you that on returning from the theater on Wednesday evening last I boarded the first theater car to W'Gabba, and owing to the car becoming overloaded I had to sit on the hand railing on top of the car, with the result that I had my trousers destroyed by being caught on the stone pillar at the north end of the bridge.

As I suffered sufficiently by having to escort a lady home with my pants minus the seat I am sure you will deem it only just that you should suffer the inconvenience of the loss of their value, viz.: £1 1s.

If you have any reason to doubt my assertion you may refer to Mr. ———, who was also a passenger.

I will send you the damaged pants if you wish it.

Trusting you will see the justice of my demand and forward cheque for amount at your earliest convenience,

I am, sir, yours faithfully,

———— ————.

Fighting Snow in Newport, R. I.

A snow storm is unwelcome to most railway managers, no matter how well one may be prepared to keep the track clear, and during a heavy storm continuous and arduous work is usually required from every member of the operating force, from the switchman to the superintendent, to keep the tracks open. Many of the New England roads suffered severely from the blizzard the latter part of November. A good idea of the amount of snow which fell at that time in localities where the fall is comparatively light at most times, is shown in the accompanying engraving, which was taken on the Newport Street Railway, at Newport, R. I. The means employed by this company for combating this snow storm are the snow plow, with its long nose set at an acute angle, a snow shovel brigade, and, coupled with these, vigilance and prompt action.

LARGE DRIFT IN NEWPORT

Combined Street Railway and Lighting Station

The Hagerstown Railway Company has recently completed a new station, from which power will be supplied for operating the street railway system and the electric lights for city and other service, both industries being controlled by the same company. The new building is of brick, tasteful in design, with a ground dimension of 80 ft. x 116 ft., and wing for boiler room 45 ft. x 50 ft. The generators are to be driven from a jack shaft, which extends the whole length of the building down the middle of the floor, and is provided with Hill clutches for coupling the different sections. The power is generated by three tandem compound condensing engines of the Standard type, manufactured by the Harrisburg Foundry & Machine Works. They are of the single piston-valve type, and so far are operating to the entire satisfaction of the management. Two of the engines, which are each of 400 h.p., are located at the ends of the shaft, on the opposite side from the generators, and transmit their power by belts to the shaft. A third engine, a 300-h.p. machine, is belted to the middle of the shaft.

The street railway generator equipment consists of two 325-kw. machines of the General Electric make, which are belted from the extremities of the shaft. An 80-kw. generator provides the power for stationary motor service. The lighting generators consist of one 3000-light alternating machine, one 1500-light alternator, one 125-light Brush arc machine, and four 50-light Schuyler generators, all driven by belts from the shaft. The belts are all of Chas. A. Schieren manufacture.

The boiler equipment consists of three boilers of the Berry type, aggregating 550 h.p., and were manufactured by Robert Wetherell & Company, of Chester, Pa.

Among the auxiliary steam equipment are the condensers and steam piping, which were furnished by Best, Fox & Company, and a Spencer damper regulator, which controls all the dampers of the three stacks.

The switchboard is of black and blue marble, the blue portion being occupied by the lighting instruments. This, with its equipment, was furnished by the General Electric Company. The equipment seems to be well designed for the purposes required. As it was necessary to operate both the lighting and railway generators from the same engine, it was found better to install the shaft with clutches and belting, so that either engine, or all combined, can be coupled to each or all of the generators. For these reasons direct coupled units were not installed. The plant has been erected and the machinery installed under the direct supervision of C. W. Lynch, president of the company, the designs having all been made by W. C. Happerley, superintendent.

Business During 1898

In spite of the fact that the United States was engaged in a war during the past year, the electric railway business has been more prosperous than ever before, and probably a greater amount of contracts for new equipment have been awarded than in any previous year. It is certainly true that most manufacturers have not complained of lack of orders during this period.

From data collected recently by the STREET RAILWAY JOURNAL on the output of certain manufacturers of rolling stock, it is estimated that from all the shops in this country manufacturing street cars, between 5500 and 6000 cars were turned out during 1898. During the same period it is estimated that the output of electric car trucks in the United States was from 8500 to 9500, and of car wheels for street railways from 125,000 to 150,000. A certain proportion of the two former and a small percentage of the latter were undoubtedly for export, but it is impossible to say just what proportion was sent abroad.

The secret of success in handling damage cases lies, no doubt, in their being properly looked after from the very start, *i. e.*, from the time they are first reported. How to do this varies as do the different cases, but no case should ever be handled by any one but an honest, careful and experienced claim agent. For such work, men must be naturally qualified; they should ever have the interests of their road at heart, and yet not blinded by too great a prejudice in its favor; they should have sound, shrewd judgment, and be painstaking and careful of detail to the highest degree. Like the true physician, they should be of a happy, calm temperament; and also, like him, should ever be ready to answer a call. The successful claim agent should have the faculty of handling all sorts of people without friction. His keen perception should reveal to him the nature of each case, but he should never betray anxiety for settlement.—From address delivered at the Niagara Falls Convention, 1897.

STREET RAILWAY JOURNAL

FEBRUARY, 1899.

PUBLISHED MONTHLY BY

THE STREET RAILWAY PUBLISHING COMPANY

MAIN OFFICE:
NEW YORK, HAVEMEYER BUILDING, 26 CORTLANDT STREET.

BRANCH OFFICES:

CHICAGO.....Monadnock Block.
PHILADELPHIA.....931 Chestnut Street.
LONDON.....39 Victoria Street, Westminster.
PARIS.....50 Boulevard Haussman.
COPENHAGEN.....V. Faber-Madsen, 9 Valby Langgade.
BERNE.....Chas. Rochat, 15 A Falkenburg.
MILAN.....Guido Semenza, Via Paleocapa, 4.
VIENNA.....E. A. Ziffer, I Giselastrasse, 9.
MOSCOW: Alexander L. Lineff, 9 Gt. Tchernishevsky Pereulok.

Long Distance Telephone, "New York, 2664 Cortlandt,"
Cable Address, "Stryjourn, New York."

TERMS OF SUBSCRIPTION.

In the United States and Canada..... $4.00 per annum.
In all Foreign Countries, per annum..... $6.00 / 25/ / 31 fr

Subscriptions payable always in advance, by check (preferred), money order or postal note, to order of C. E. WHITTLESEY, Treasurer.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Havemeyer Building, 26 Cortlandt St., New York.

Apropos of the revival of active interest in increased rapid transit facilities in New York city and the more favorable attitude of the municipal authorities on the question of building an underground electric railroad, we take occasion to again point out the impossibility of avoiding or long postponing the building of such an underground road, or of looking forward with equanimity to the future congestion of traffic on Manhattan Island if greatly increased facilities be not provided. The new electric surface lines are proving so immediately and unexpectedly popular that almost as soon as they start into operation the traffic on all the longitudinal lines is dangerously near the topmost limit of capacity. We know now quite closely the ultimate capacity of the elevated lines, except for possible "double decking," and we know also that there is an enormous number of new apartment houses and private dwellings going up in the northern portion of the Island. These buildings must have tenants and the tenants must have transit accommodations for their every day marketing, as well as for business purposes, and better rapid transit facilities are even to-day a crying necessity. What wonder is it, then, that the political powers behind the throne in New York city should execute a *demivolte* and consent to the further consideration of rapid transit plans on broad gage lines—what wonder also that those at present in charge of, and responsible for the transportation of the people of the city of New York should give most serious consideration to financial and engineering problems incident to the construction of such lines, and should resolve to build them as a supplement to the present almost overburdened facilities.

About ten years ago, just before the beginning of the "boom" in electric railroading, there were well-defined rumors that a European syndicate was forming to introduce compressed air as a motive power for street railways on an extensive scale. The immediate success of electricity prevented the syndicate's plans from being carried to fruition, and compressed air has not since figured as a competitor of importance in the street railway field. Within the past five years, however, further experiments in compressed air have been carried on in this country on a somewhat extensive scale, and the results have been such that ample and powerful financial support has lately been secured for compressed air as a motive power. The first large effort of one of the new syndicates will be directed toward the building of "auto-trucks" for handling the trucking business of large cities, now done by horses, and the parent company purposes licensing local companies for this purpose. It is expected, too, that cabs and possibly even omnibuses will next be taken up. Considerable experimental work has also been done in the street railway field, as has been duly chronicled in the STREET RAILWAY JOURNAL from time to time, and within a few months, a twenty-car, five-mile crosstown line is expected to be in operation in New York City by compressed air. It will need a year or more of full operation of this line before even a preliminary idea of the operating expenses of compressed air can be obtained, although reasonably close estimates of everything except depreciation and "contingencies" is now, perhaps, possible. What has been so far demonstrated in New York is, first, that compressed air motor cars will run, and with fair satisfaction to the public; second, that an amount of air, compressed to 2,500 pounds pressure, can be stored out of sight in an ordinary street car, sufficient to run a car from twelve to fifteen miles, under ordinary conditions of track and service, and somewhat more under favorable conditions; and, third, that air at this high pressure can be compressed and "bottled" with reasonable safety, and the pressure reduced by simple means to a point where it can be used in the motors. What is not demonstrated is whether under all working conditions which street cars and trucks have to meet, including collisions, etc., absolute safety to the public can be always assured; whether heavy grade work such as is frequently found in city streets can be done by compressed air motors or any form of self-propelled car employing reciprocating

motion; and whether the costs of motive power and of maintenance will be comparable with electricity. All these demonstrations will come in time, and what is now certain is that experiments on a larger scale than ever before made in this country are already instituted, and will be vigorously prosecuted to a definite conclusion.

The cost of copper has been constantly rising for the last year and more, and, according to all indications, will continue to increase, especially if the consolidation of the copper mining companies of the Northwest, which has been proposed in Boston, the financial headquarters of the American copper interests, is consummated. The use of the metal is, of course, also constantly increasing, and the extent of its employment in the electric railway industry makes the question of its market price an extremely important one to street railway companies. Efforts to find a substitute for copper as an electrical conductor have been numerous. As is well known, the rails are being employed for carrying the return current to the power station much more extensively than formerly, and underground supplementaries are going out of use. Some companies have even gone so far as to lay mains of buried rails, well bonded together, for connecting the tracks with the power station. The chief reason for this, of course, is to save the expense of the copper, but measures of this kind are, on the whole, poor substitutes, so that the announcement of the aluminum manufacturers that they can compete in price with copper, comparing the two metals in their current-carrying capacity, is interesting. Aluminum is practically three and one-half times lighter than copper, and the pure metal has a conductivity of about 63 per cent that of pure copper. Upon these figures as a basis, it is estimated that for electrical conductors of equal conductivity aluminum at twenty-nine cents a pound is cheaper than copper at fourteen cents. The tensile strength of pure aluminum may be greatly increased, without much loss in its conductivity, by properly alloying it, and it is then well fitted for aerial wires, owing also to its lightness. The chief drawback to its use as an electrical conductor at present seems to be the difficulty of soldering or brazing it, but it is said that this objection is being overcome. The material has been employed as an electrical conductor to a limited extent on some of the long-distance lines in the country, chiefly for telegraph and telephone work, and any advances made in the method of adapting it to electrical uses will be watched with interest.

It is the impression in some quarters that under the Light Railways Act, it will be possible to duplicate in England and other parts of Great Britain, to some extent at least, the interurban electric railways now being so extensively introduced in America, but present indications seem to be that while there may be some construction of this kind, it will be in no way commensurate with that of America or with the development of the electric tramway industry. The Light Railways Act was passed principally with the intention of encouraging the construction of lightly built and inexpensive steam trams for the cheap carriage of agricultural products and goods to the nearest trunk line terminal, in cases where the amount of the traffic would not warrant the construction of a regular railway. The control of such light railways is vested in a body called the Light Railways Commission to whom the applications for the construction of such lines must be made. The restrictions on the construction of these roads are made less severe than those which govern tramways proper, and the procuring of the necessary powers is much less protracted and expensive than is necessary for tramways. The intention is thus to encourage the building of these roads for the benefit of the agricultural class who could thus ship their products at a much less expense than that required for cartage. In spite of the fact that the provisions are in many ways liberal, as described, the development of light railways in England has been exceedingly slow. Although those at present are operated by steam, there seems to be no legal objection to their use of electricity as a motive power, but there are a number of reasons which will serve to prevent the rapid development of these lines, even with electrical equipment. One of the difficulties will be that the city tramways are generally controlled by the municipalities with whom it is necessary to make arrangements for running rights and the use of current. Another, and seemingly a more serious objection to those who have studied the development of similar roads in America, is the limitation of speed. This limitation depends upon circumstances, but the usual maximum is twelve miles an hour. The first objection may be overcome, because the right of municipalities to build roads beyond their own limits is not fully determined and they surely ought to be willing to make any reasonable arrangements for terminal facilities with the light railroad companies, because they must recognize the value of the suburban and interurban feeders to their own systems. The limitation of speed, however, is a very great drawback and seems, under the present conditions of public sentiment, almost insurmountable, owing to the opposition of the vested interests of the steam railroad lines. The latter are extremely powerful in England and represent an enormous amount of capital with securities widely distributed. Any attempt to interfere with the earning powers of any of these roads by the construction of high speed electric railways built along the highways *as competing lines* is naturally almost doomed to defeat, although the conditions for their construction be otherwise favorable. On the other hand, the tramway development in England will, of course, be very large, as practically all the corporations which own tramways, or will soon acquire them, are requesting powers to equip with electricity. Public sentiment in England is favorable to the control of the tramways by the municipal corporations, who have undertaken the management of quasi-public enterprises to a much greater extent than in America, Outside of the tramway field there will undoubtedly be a large development in the electrical equipment of suburban and feeder branches of the steam railroads proper and even—in the not far distant future—of the main trunk lines themselves. There is probably no other country in the world that offers the opportunity for high speed electric service as that furnished by the English trunk lines, with their private rights of way, two and four tracks, no grade crossings, and their frequent train service. The population density in the cities and country is very great and these roads can afford to give their patrons far better service than at present.

A New General Formula for Train Resistance

The alchemists of old sought diligently for the philosopher's stone, the inventors of a later age for perpetual motion, and engineers of the nineteenth century have been almost as eager to obtain a general formula which shall reconcile all existing data and experiments upon train resistance. The first two objects of effort are now known to be unattainable, and the third has until now baffled the best minds in the railroad profession. Only a month ago "Locomotive Engineering," which for years past has devoted special attention to this subject, said editorially: "We do not believe that it is possible to devise a formula that will show an approximation of the resistance due to different kinds of trains at different speeds when train tons are the basis of calculation."

A general formula which appears to be applicable to *passenger* trains of all weights, running at all speeds up to the highest limits so far reached, has been lately worked out, however, by John Lundie as a result of a long series of tests of trains in actual service, and is here given to the engineering public for the first time. His methods of obtaining data are decidedly different from, and much more satisfactory than those commonly employed hitherto, where indicator cards of engines drawing trains at constant (?) speed on level (?) track have been made the basis (with an arbitrary allowance for engine friction) of estimates of resistance per ton moved. In order to be of any value such tests must be made in long distance runs, and it is almost impossible to find a hundred miles or more of absolutely level track for the purpose, while it is also difficult to obtain perfectly uniform speed even on a dead level. Mr. Lundie's method of determining train resistance is based on an examination of the speed curves of a train when *coasting* The possibilities of such a method will be instantly evident to an engineer, and it may be said, at once, that the results warrant a decided predisposition in its favor. It is not only possible to obtain the gross resistance due to track and journal friction and air resistance combined, but to differentiate between the air and the friction elements. The frictional resistance of a train being reasonably constant within somewhat wide limits of speed, the speed curve should be a nearly straight descending line from full speed to a point somewhere near a full stop. Now the actual speed curve dips below this straight line, as seen in Fig. 2, clearly showing a decreasing retarding force (due to air resistance), with decreasing speed.

In Fig. 1 are shown in graphic form the results calculated from more than 150 runs made by Mr. Lundie with trains of different weights on the South Side Elevated Railroad, of Chicago. It will be seen that these results, expressed by the location of points on the diagram, cluster around "straight line curves," and that these lines intercept each other, with surprising accuracy, at a single point located at a definite distance above the origin. This indicates, of course, that the first step in obtaining the final formula has been reached, in the establishment of a constant, representing the minimum possible train resistance for all speeds and weights, and it is interesting to note, by the way, that in none of the recorded experiments so far made on passenger or freight trains of all weights has the resistance per ton been less than the figure indicated by this constant—4 pounds.

Mr. Lundie's formula is as follows:

$$R = 4 + S\left(0.2 + \frac{14}{35 + T}\right)$$

where.

T = the weight of the transportation unit in tons (2000 lbs.).

R = resistance in pounds per ton.

S = speed in miles per hour.

It will be seen at once that unlike most previous formulæ, there are here two variables after the constant, namely speed and train weight. Many other investigators have endeavored to accomplish this, but unsuccessfully, and in the formula which has been in most general use in engineering hand-books, that of D. K. Clark, speed only appears as a variable. From a careful study of his

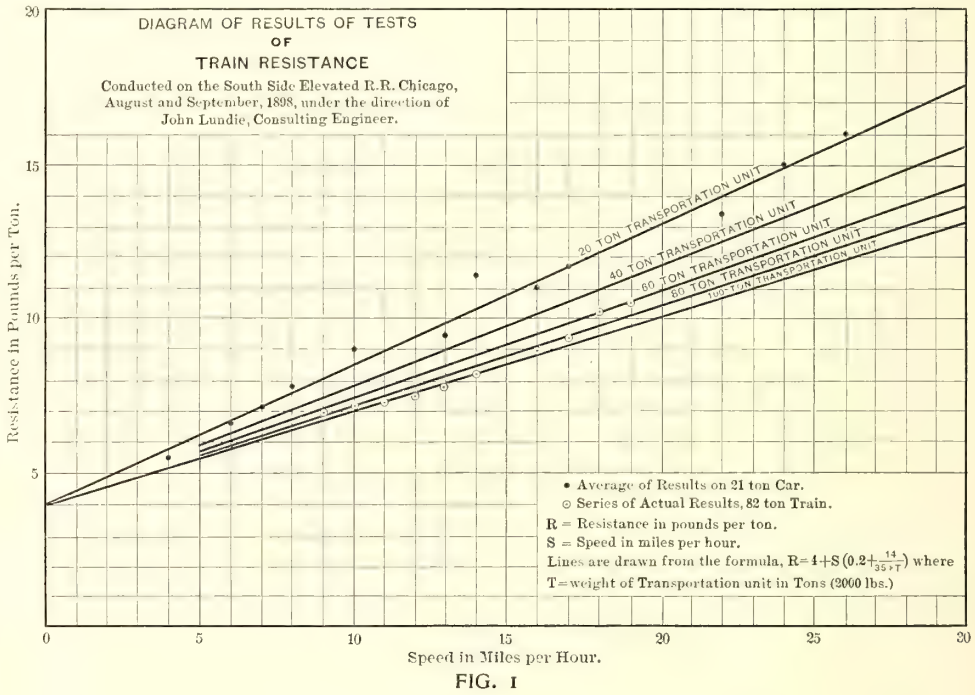


FIG. 1

results, Mr. Lundie developed the formula on the following mathematical basis: the expression by which "S" is multipled is proportional to the tangents of the angles made by the lines developed for different weights, as shown in Fig. 1, and is the characteristic of a rectangular hyperbola which (throughout the range of tests made) co-ordinates quite accurately the relations between train weights and the inclinations of the lines mentioned for corresponding weights. The term 0.2 is an intercept on the axis of y; 14 is the constant product of x and y, with the intersection of the asymptotes as origin; and 35 is an intercept on the axis of x.

The test of any formula lies in its application. Gaged by this test, Mr. Lundie's formula unifies in a remarkably close manner nearly all recently published experiments, together with other formulæ of more limited application, as will be seen by an inspection of the accompanying table. The Stroudley, Sinclair and Dudley tests of train resistance scheduled in this table were brought together by A. M. Wellington in the "Engineering News" in 1892, and referred to as intrinsically worthy of confidence on account of the careful manner in which they were made. To these

we have added further experiments made on the Philadelphia & Reading Railroad in 1889, and on the Central Railroad of New Jersey in 1892, so that a fairly complete range of train weights from 200 to 400 tons, and of train speeds from 40 to 70 miles per hour is given in the table. The Lundie formula checks up all these tests very closely, though in all but one case the results obtained by its use are slightly higher than the observed results. In this connection it may be noted that Mr. Lundie obtained his speed figures by positive methods, having found that speed recorders for variable speeds are not sufficiently accurate owing to the inertia of the moving parts.

These tests are all for heavy railroad passenger trains, upon which Mr. Lundie himself has made no experiments. For trains of from 20 to 100 tons, and for speeds of from five to thirty miles per hour, the Lundie formula is accurate, inasmuch as it is obtained directly from 150 or more observations made by Mr. Lundie in Chicago, as before stated. For lighter units still, the formula agrees with the results of private tests made by several of the great electric companies, and checks very well indeed the Clark formula

$$(R = \frac{S^2}{171} + 7.16),$$

bearing in mind that the latter is generally admitted by engineers to be from one to two pounds too high.

Now it need scarcely be pointed out that when a formula of this general kind, deduced on mathematical principles from a large series of experiments within a comparatively narrow range of action, is found to be equally applicable over a much wider range, a strong presumption in favor of the soundness of its underlying principle is established. It seems practically certain, therefore, that the Lundie formula is thus applicable to the whole range of passenger train traction on straight, level, exposed track in a calm atmosphere. It cannot, however, be said to be applicable to street cars running on gritty or dirty rails, and, in fact, it is unfortunately too probable that no formula whatever can be devised for street railway work for which a large factor of safety would not have to be allowed in practice to provide for great differences in condition of track.

An interesting question now arises as to whether the Lundie formula can be made, with some modifications, applicable to all kinds of train transportation, freight as well as passenger. It does not check the most recently obtained data for exceedingly heavy trains. Tests on the Chicago, Burlington & Quincy Railway, made by the old method of engine indicator diagrams, checked by dynamometer car, show that a 940-ton train of loaded freight cars, running at 20 miles an hour, has a resistance on a straight, level track of 5.5 lbs. per ton. By the Lundie formula this would have been 8.3 lbs. per ton. An extremely heavy train of freight cars on the New York Central, weighing 3428 tons, had an average train resistance, at 20 miles per hour, of about 4 lbs. per ton, or the limiting resistance by the Lundie formula as expressed in the first constant. Other tests on fairly heavy freight train work recently made have shown approximately 6 pounds per ton as an average, when track conditions were good, but these results vary greatly with the condition of the track.

Now it being reasonable to suppose that with the heaviest freight train work, the train resistance will approach the minimum, and the New York Central experiment above referred to, indicating that this minimum is Mr. Lundie's first constant of 4, it would seem that the latter's first constant within the parenthesis, namely .2, must be inapplicable to very heavy freight-train work, and should be, in fact, modified by a variable, probably T. It would be interesting, therefore, to bring together and plot in diagrammatic form, reliable results of a large number of freight-train tests taken with different weights and speeds, to see if a modification of the Lundie formula cannot be made for general application to the heavy class of work, as well as light, and we are inclined to believe that were this experimenting once done there might quite possibly be found a common ground of reconciliation between the two grades of service, by which a formula possessing the general characteristics developed by Mr. Lundie could be made applicable to the entire range of railroad transportation.

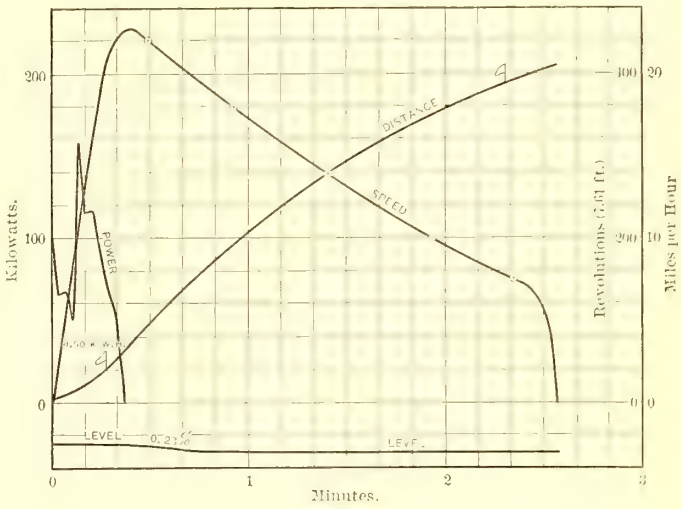

FIG 2.

TABLE SHOWING APPLICATION OF LUNDIE FORMULA TO TRAIN RESISTANCE TESTS.

Test Made By	Year.	On.	Mem.	Average Speed. Miles per hour.	Train Weight. Tons.	Train Resistance. Observed.	Train Resistance. Lundie Formula.

The Money Centers and Tramway Opportunities of the World

I.—Europe.

At this time when enormous stores of capital are concentrated in a few great money centers of the world waiting investment in more profitable channels than those immediately in sight, and meanwhile earning little or nothing more than the cost to the bankers of caring for them; at a time, too, when all kinds of "wild cat schemes" are being promoted, and mining and other similar enterprises involving serious risks and possibilities of loss of principal are finding supporters and investors, it is not surprising that more and more attention is being given by the possessors and custodians of capital to the almost limitless field of electric railroading in its various phases—city, suburban and interurban—operating, projected or ready for the projector, in all parts of the world. The flow of money into these channels, however, has hardly more than commenced, if we consider the vast number of opportunities which are offered by the densely populated countries of the old world, so large a percentage of whose population is collected together into cities, towns and villages but short distances apart.

It will be useful, therefore, in the interest of capital seeking investment to take a broad survey of the world and note what may and what may not be done in the different countries, and what are the most promising openings for immediate effort. Such a survey, if thoroughly made, would include a discussion of so many elements of general and special problems of investment as to be entirely beyond the limits of any paper, magazine or even book, but there can here be indicated in brief space the lines on which further work can be done in particular countries or sections.

The four great money markets of the world where capital can be obtained for all kinds of home or foreign enterprises, are London, Paris, Berlin and New York—all charged with the duty of finding an outlet for the surplus profits of great manufacturing countries. It has only lately been possible to place New York in the list of first-class international money lenders, as American capital has been so far absorbed in self development and has even been a borrower in the world's money markets to assist in this process, but now, while self development is by no means completed, our annual surplus investment fund is so enormous, due to growing manufacturing, commercial and agricultural profits, that we can no longer use all our own money to advantage, as is shown not only by the low rates of interest prevailing in America, but by the large sums of American money afloat in the markets of Europe, but subject to call home at any time.

In London there is now little or no difficulty in obtaining money for reasonably promising foreign tramway projects, but there is as yet comparatively little real effort made to find them. In spite of low interest rates and large accumulations of money, the London banker as a rule limits his efforts to passing upon projects which may be brought to him, and leaves to promotors the task of taking the initiative and finding the opportunities. Berlin, on the contrary, is eager, active, outward-looking and anxious to find the money making chances. Hardly a ship leaves a German port without bearing an engineer sent by some financial concern to investigate a proposition or a possible opening in some distant portion of the world. German bankers thoroughly understand the profits in electrical enterprises and are anxious to extend the range of their investments. In fact, the recent serious stringency in the German money market is attributed to the immense amounts of money which have flowed into electric railway and lighting enterprises during the past two or three years, many of which have not yet begun to develop their full earning power. Paris has been somewhat slower than Berlin in understanding tramway profits, but is now making heavy investments at home, in Italy, along the Mediterranean, and to some extent in Russia. Brussels, which has always been the headquarters of several syndicates operating horse tramways in all parts of the world, is increasing its investments in this field, frequently in conjunction with German or French capital, by which Belgian capital has been to some extent overshadowed.

America has poured immense sums of money—probably over $1,000,000,000—into street railway development at home, but has so far made little effort to enter into competition with European money centers in the building or promotion of new enterprises abroad. New York is losing great opportunities, for its capitalists thoroughly understand and appreciate the value of electricity for transportation purposes and need no education. Perhaps a change is coming with the new ideas of "expansion," and this certainly ought to be the case, for no field of international investment offers greater promises of satisfactory return.

It is quite certain that, in spite of occasional exceptions, there will be little interchange of capital for tramway investment between the four great money countries themselves. America has money enough and to spare at low rates of interest for American enterprises, and needs none from Europe. Great Britain owns two or three tramways in Germany and has a little capital in France, but this was placed there before the Germans and French waked up to what was going on. It goes without saying that there is no French capital to speak of in Great Britain, and little or none in Germany. German capital is, however, quietly and unostentatiously at work through international banking houses in Great Britain and France, but still to no great extent, and not to the exclusion of local capital in the same investments.

Both German and French capital is found in Switzerland, in Belgium, and in Russia, German and local capital has almost a monopoly in Austria-Hungary, British and German capital controls South and Central America, while all the capitalist nations of the world are gathering their forces for an onslaught upon Eastern Asia, which is the great virgin money making field of the world to-day.

It is hard for the newer countries of the world to conceive how densely settled are the older ones. Observe the following population densities of continents:

Continent.	Inhabitants per sq. mile.	Continent.	Inhabitants per sq. mile.
North America	12.0	Asia	47.9
South America	5.4	Africa	14.2
Europe	93.0	Australia	1.1

Is it possible that Europe will long be contented with a much smaller steam railroad mileage than America and with higher prices for transportation, when the alternative is presented of profitably operating thousands of miles of electric railways in a territory where the population density is over seven times that of America? No matter who or what is injured in the process, better transportation facilities must and will be given to the people of Europe.

In the accompanying table are shown the number of cities of above 20,000 (usually) inhabitants found in the principal countries of Europe, the population of these cities, and the percentage of this city population to the total population of the country. From such figures a quick idea of the relative importance of each country from the municipal transportation point of view may be obtained.

NAME.	Total Population.	Population per Square Mile.	CITIES ABOVE 20,000 INHABITANTS		
			Number.	Population.	Per Cent to Total Population.
Great Britain	37,731,415	315	382	20,190,568	53.5
Germany	52,279,901	251	161	11,449,000	21.9
Russia (in Europe)	103,703,213	47	87	7,690,159	7.4
Italy	31,102,833	281	62	5,334,000	17.1
France	38,342,948	189	60	7,323,340	19.1
Austria-Hungary	41,358,886	171	41	3,923,558	9.5
Spain	17,565,632	88	22	2,179,256	12.4
Netherlands	4,859,451	384	21	1,632,555	33.6
Belgium	6,410,783	564	17	1,565,809	24.4
Sweden and Norway	6,920,177	17	14	866,158	12.5
Roumania	5,800,000	120	8	533,382	9.2
Switzerland	2,986,848	183	8	449,846	15.1

Great Britain.—Existing laws and customs, short time franchises and strict regard for private rights and vested interests are all against the rapid introduction of improved transportation facilities in the British Isles, although much has been done during the past three or four years to overcome prejudice, and considerable headway has been made. Nearly all desirable investments will be taken at home and there will be little or no chance for outside capital, unless working in conjunction with home interests. German and American capital is, however, actually interested to some extent in British tramway development, chiefly through international banking and manufacturing houses. Public sentiment is steadily tending toward municipalization of city enterprises, including that of transportation, and unless this should be checked by poor financial results or admittedly imperfect operation, there will be less and less chance for private capital to engage in such enterprises. There is yet to be built, however, a great network of light railways, to be operated probably by electricity, supplementing the present steam railroad service, and providing for cheap, pleasant and frequent service between cities and towns. Such work will probably be left, for the present at least, to private capital, and if the latter can secure rights of way and terminal privileges within the limits of the cities which they serve, there is quite enough profit in prospect to satisfy the most rapacious of the investing interests. The location and building of such railways will necessarily take time, however, and will be met by vigorous opposition on the part of the existing railroads, unless the latter themselves undertake the work of expanding the transportation facilities of the British Isles, which is quite probable.

Germany.—With nearly half as many cities as Great Britain, and more than half the city population Germany is far more progressive and active in transportation matters, and electric railways are being installed all over the Empire. Here again local capital is dominant and sufficient, and there is little chance for foreign, although in Germany as in Great Britain, immense quantities of American tramway apparatus and material are sold. The home tramway development is controlled to a very large extent by several great syndicates or groups, each composed of banks, promoting companies and manufacturing companies. [See STREET RAILWAY JOURNAL (International Edition) for July, 1898, page 389]. These different groups enter into competition with each other to secure existing and new enterprises, and the amount of capital at their disposal is almost unlimited. Nearly all new enterprises are promoted by some one of these syndicates, for the money influence of the country is very largely concentrated in their numerous banks, and individual outside enterprise will naturally be discouraged. On all good propositions foreign capital can generally be outbid in one way and another, interest rates in Germany being quite low.

Russia.—Russia has been until recently a *terra incognita*—a country jealously shutting itself up and keeping itself aloof from the rest of the world so far as possible. Now, however, foreign enterprise, though hardly welcomed, is not repelled, and in spite of high protective duties, the importations of outside products are very heavy. Among foreign manufacturers none have been more persistent and aggressive than the Germans and Americans, and representatives of manufacturing and business houses of both countries are overrunning the vast Slav Empire and are finding and reporting opportunities for investment. The Russian Government is a borrower in the world's money markets, its borrowings being largely for the purpose of accumulating a sufficient gold reserve to change its monetary system from silver to gold, and as a consequence it has enormous stores of gold already locked up and taken out of circulation. There will doubtless be more or less disturbance of the financial fabric when this change takes place, and provision should be made accordingly, but in general it may be said that with its eighty-seven cities in European Russia and thirty-seven in Asiatic Russia, there should be great chances for money making in the construction and operation of Russian tramways. Individually the Russians are probably well to do, though statistics as to wealth per capita are missing, but the building of the great Siberian railway to the Pacific Ocean and other large projects which the Russian Government has in hand for the development of the immense natural resources of the Empire will doubtless increase individual wealth, but not in proportion to the possibilities for investment.

Italy.—It is somewhat surprising to find that Italy has a larger number of cities above 20,000 inhabitants than France or Austria-Hungary. Italy is not wealthy as a country or in its individual citizens, and there is a great deal of "picturesque poverty" in the peninsula. Nevertheless, it has many tramways already established and more possible locations for others, although to many people it seems a desecration to think of overrunning the land of Cæsar with such twentieth century improvements. German and French capital is quite active in Italy, and frequently comes into competition. The English also own two or three tramway systems, and local capital is, of course, interested to a large extent. The field here is well worth investigation by Americans.

France.—France is self contained and self sufficient so far as money investments are concerned, but is using large quantities of foreign (chiefly American) tramway apparatus and material, purchased by companies formed primarily to control and operate tramway properties. These companies have secured French and, in some cases, Mediterranean rights for handling American apparatus, on advantageous terms, and have not until now found a large enough margin of profit in manufacturing to warrant the building of apparatus in France itself, in view of the larger margins obtainable in purchasing and operating tramways. The principal tramway companies of the country are gradually coming under the control of some one of these promoting corporations, and are thus losing their distinctive character. A number of American engineers and business men are associated

with these French syndicates, and their experience in tramway construction and operation is of great value.

Austria-Hungary.—Extreme Chauviniste or high protectionist ideas prevail in the Austro-Hungarian Empire, and great jealousy of foreign inventors or manufacturers is found as a rule. This can be overcome only by diplomacy, and much of the manufactured products which are supposed to be of home manufacture is, in reality, made in Germany or elsewhere. Germany has a great advantage over other countries in dealing with the dual empire in that so large a portion of the latter's population are German born or of German descent. In fact the difficulties of foreigners doing business at all in a country containing so many different peoples speaking different and troublesome languages are very great, and as a result there is little interference with German and Austro-Hungarian manufacturers in their efforts to keep this business to themselves. The number of cities and the amount of city population is certainly tempting, however, to outsiders, and transportation facilities are by no means perfect though much better in some respects than in other countries of Europe.

Spain and Portugal.—British capital has done much in Spanish tramways during the last two or three years, and those of Madrid, Barcelona, Lisbon, Cartagena, Seville, and others are in their control. France is the great European power most nearly in touch with these two countries, however, and should have decided advantages in obtaining their business. Germany, too, will be favored, while America, in view of recent war complications, would have little chance of success in obtaining valuable concessions. The Spanish people being naturally somewhat indolent in private life, are good patrons of street railways, as is shown in some of the Spanish-American countries as well as in Spain itself.

The Netherlands.—The Netherlands form one of the wealthiest countries of Europe, and have always been lenders rather than borrowers of money, but less in the line of railroad development than of commercial matters. Practically all the Dutch tramways are locally owned, and little is known about them outside. Rates of interest in Holland are so low as to discourage outside enterprise, while it is true, of course, that transportation by the network of canals throughout the Netherlands is so cheap as to make the field for interurban railways probably less promising than in some other countries.

Belgium.—A single great company, the Societe Nationale des Chemin de Fer Vicinaux, controls a large proportion of the tramway and "light railway" mileage of Belgium—no less than 862 miles in all.

As above stated, the Belgians are fully alive to the profits of tramway operation, and have never had to seek outside capital for the development of home propositions. The only way of obtaining a share of tramway development profits in Belgium would be to join forces with local capital, and even this is difficult unless a special and substantial advantage can be shown to the local capital for admitting outsiders.

The Scandinavian Countries.—Norway, Sweden and Denmark are thrifty and prosperous countries, and for ordinary capital requirements do not need to look outside their own borders. Nevertheless, there would probably be no actual repelling of outside capital there to seek investment, but the difficulties of languages would be such as to make it rather hard to form joint syndicates. At present commercial relations with Germany are seriously strained and may quite likely be almost entirely broken off for awhile at least on account of what is considered the high-handed action of Germany in expelling the Danes from Schleswig-Holstein. In trade matters England and the United States would be favored, and there is a very cordial feeling, particularly in Denmark, forAmerica and Americans.

Switzerland.—Switzerland is, in language, part German and part French, and its affiliations are also divided between the two adjacent countries. Nearly all the railways and tramways of the Republic are owned by the cantons, and what private capital is so invested is chiefly French and German. English and American capital would find it difficult to secure a foothold here.

The Balkan Peninsula.—Turkey has for a hundred years been a bone of contention among the European powers, and it can hardly be said that any has permanently obtained great predominance in its councils. At present its cities are being closely examined by a number of European capitalists with a view to tramway possibilities, and it is probable that concessions may be granted in Constantinople and elsewhere. American capital would probably have little chance of success, as it would doubtless be the Sultan's policy to use his franchise conveying powers to further his purposes with some one or other of the European powers.

The other countries of the Balkan Peninsula are more or less subject to European influence, and the conveying of franchises would naturally be matter of some delicacy and would require considerable diplomacy to effect. British capital has so far been successful in several cities of the peninsula.

Frequent and severe punishment for petty offenses should be abolished and a code of rules established worthy of the men and the business they represent. The almost universal practice in punishing minor offenses is to "lay off" the employee from one to ten days, without pay, which is in effect a fine of from two to twenty dollars. The man is soured, his family suffers from the loss of earnings, and if the man happens to be a conductor it is not surprising if he tries to "get even" by nipping fares. The practice is still adhered to by many railway companies, and the offenses which it is supposed to correct still continue. Such a practice would not be countenanced in a manufactory, a store, or in commercial affairs; why should it be on street railways? If the man is valuable enough to be retained in service, why should his family suffer the loss of his wages? If the man were permitted to continue at his work and one-half the amount he would lose by laying-off were assessed as a cash fine, the practice would be condemned in unmeasured terms both by the press and an indignant public. If employees are not amenable to reprimand administered in a proper way, then they have not your welfare at heart, and should be dispensed with altogether.—From paper read at the St. Louis Convention, 1896.

All foremen and sub-foremen should be impressed with the idea that all men under their charge should be treated in a gentlemanly manner, and with the utmost fairness; that there shall be no favoritism in recommending men for promotion, or in shielding them from punishment.—From paper read at the St. Louis Convention, 1896.

Again, as a second suggestion, I wish that we might induce every street railway company in this country to take an active part in this, our association. I sometimes fear that some of the smaller companies, who, as yet, by reason of location or character of travel, have not found it to their advantage to adopt the more recent kinds of motive power, but are still using horses, feel that they have no place in our gatherings.—From address at the Atlanta Convention, 1894.

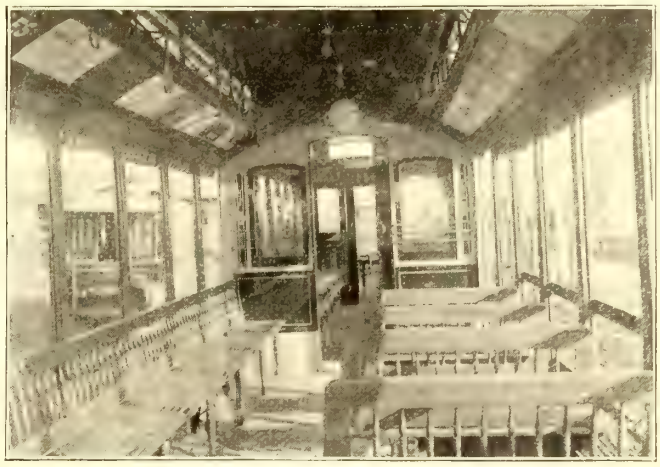
Improvements in Denver

The Denver Consolidated Tramway Company has recently been equipping some of its cable railways with electric power. In its new track construction the company is using a 72-lb., 6-in., 60-ft. T rail, mounted on 5 in. x 7 in. x 7 ft. creosoted ties, ballasted and thoroughly tampered with gravel.



The company has also been experimenting on splicing some of its old 16-ft. cars, each with an ordinary seven-bench trailer to make a 39-ft. combination car, which is a very popular type of car in Colorado. The method of splicing employed is as follows: The cars are mounted on a framing of two 6-in. I-beams extending the entire length of the car, the beams being joined together by stout oak pieces. The running boards are then removed from the trailer and wooden guards put on the sides of the open car, which is fitted with long storm curtains in addition to the ordinary shades. The seating arrangement of the open portion of the car was changed by the removal of the seats on one side and the substitution in their place of longitudinal seats, made up to a certain extent from the seats removed. The object of this arrangement was that, while it afforded nearly the same seating capacity as before, it enabled the conductor to collect the fares more quickly and with perfect safety. The engravings herewith give a good idea of the external appearance of the car and the seating arrangement of the open portion.

The entrance is near the middle of the car at the end of the closed portion of the car, and is of ample width, allowing passengers to get on and off the car at the same time. The company is considering the advisability of protecting this entrance with an ordinary gate or guard for the purpose of minimizing accidents, resulting from people stepping off the car while in motion. It is expected that a large number of cars will be equipped in this way. The closed portion is always at the front end of the car which is always run in the same direction.

EXTERIOR OF COMBINATION CAR

All of the company's cars have recently been fitted with storm fronts, similar to that shown in the engraving of the exterior of the car. A curtain, not shown in the engraving, is put on the motorman's left-hand side for the purpose of protecting him from drafts. All of the cars are now being fitted with the changeable headlight of the Crouse-Hinds Electric Company, of Syracuse, N. Y. The company has also equipped all of its cars with a fender devised by A. L. Lawton, manager of the Colorado Springs Railway. These fenders have picked up a number of persons, as well as dogs, bicycles, and in one instance, a horse. The management reports that it is well pleased with the fender.

INTERIOR OF COMBINATION CAR

Street Railway Mileage and Capitalization in America

In the accompanying inset will be found a most careful compilation of the mileage of electric, cable and horse railways in the United States and Canada; the number and distribution of the cars operated thereon, and the capital stock and funded debt of the operating companies—all arranged by states and sections of the country, and comparison made with corresponding figures for 1897. A similar table appeared in the STREET RAILWAY JOURNAL for October, 1897, in which the 1896 figures were given, and from these two compilations the general growth of the industry in America for the last three years can be understood, as well as the distribution of the increases from year to year.

Contractors for Tramways in Barcelona and Madrid

Elsewhere in this issue F. C. Armstrong describes the new electric railway systems recently installed in the cities of Madrid and Barcelona, Spain. The chief sub-contractors for the railway apparatus used in those plants were as follows:

Generators and motors—British Thomson-Houston Company (Limited).
Engines—E. P. Allis Company.
Boilers—Babcock & Wilcox Company.
Condensers and water tower—Wheeler Condenser & Engineering Company.
Economizers—Green Economizer Company.
Feed wire—Callender's Cable & Construction Company.
Car bodies—Compañia de Ferro-carrilles de Zaragoza.
Car trucks—J. G. Brill Company.
Trolley wire—Felten & Guilleume.
Rail bonds—Neptune, made by Felten & Guilleume.
Rails—Phœnix Actien Gesellschaft

Our experience has been that if the conductors and the passengers will use the transfers as we intended they should use them, we can afford to give them.—From address at the Montreal Convention, 1895.

LEGAL NOTES AND COMMENTS*

Edited by J. Aspinwall Hodge, Jr., and Robert Ernest, of the New York Bar

Heating and Other Accommodations in Street Cars

There was a time—not very far distant—when places of public concourse, such as theaters, lecture halls and churches, had no other means of heating than the foot stoves, which might be carried by some of the more luxurious members of the audience; and long after it was the universal custom to properly heat such places, it was still an unheard-of thing that any public conveyance should be furnished with any other means of heating than the hot brick or the little foot stove.

With the steam railroad there came, first, wood and coal car-heaters, and now, even these are things of the past, and in some States are prohibited by statute, the steam railroad being obliged to furnish steam heat, because of the danger of fire in case of a railroad wreck

It was some years after the street car was introduced before what was then considered a novel luxury was introduced into some of them in the shape of a small coal stove; but now that is almost universal, except where it has been supplanted by the luxurious electric heater supplied from the same current which propels the car and lights it.

As each of the inventions is introduced and becomes established, it ceases, in the public mind, and in fact, to be a luxury, and becomes a necessity; and, in passing from one class to the other, a legal obligation is created, by reason of the general rule, that in the contract between the common carrier and the passenger there is an implied agreement that the latter will be furnished with the ordinary comforts or necessities which are incident to the mode of conveyance furnished. This is the common law, and where there are statutes they have either merely declared it or have imposed additional burdens upon the common carrier by definitions of what are necessities and ordinary comforts.—(Texas & P. R.R. vs. Pierce, 30 S.W., 1122; Boothby vs. R.R., 66 N.H., 342.)

As the electric street railroad is gradually furnishing the same sort of transportation as the steam railroad, and in much the same way, it finds itself assuming new responsibilities, and becoming more and more subject to the same rules which apply to its older rival. Among these undoubtedly is the duty of heating its cars and its waiting rooms, where these are furnished as ancillary to its business at its transfer points. So far as we are aware, there is no adjudicated case of the Appellate courts upon the duty of a street car company to keep its conveyances warm, and upon its liability to passengers for illness caused by the want of proper heat.

That it is the duty of the steam railroad company to heat its cars, and that they are liable where, through negligence, they do not do so, and especially after the attention of the servants of the railroad have been called to the matter, has been more than once adjudicated.—(Ft. Worth & D. C. R.R. vs. Hyatt, 34 S.W., 677; Taylor vs. R.R., 38 S.W., 304; Hastings vs. R.R., 53 Fed., 224.)

This rule, when it shall be applied to the street car, will undoubtedly be applied with due consideration of the difference in the conditions. For the ordinary passenger upon the street car in a city, who steps into the car from the street, warmly dressed, and who leaves it after a ride of only a mile or less, is manifestly not so exposed to the elements as to raise any presumption that a subsequent illness results from such a ride, however inadequately the car was heated; and, on the other hand, upon the question of contributory negligence, a passenger on the street car can, at very small expense and comparatively little inconvenience, leave an unheated car as soon as he becomes aware that its temperature is dangerous to his health, assuming that he is riding through a city street, or is upon a line where the headway between cars is not great, and where he can procure another and better-warmed conveyance.

But when the trolley line reaches out into the country, and becomes intra-urban, the conditions grow more and more like those of the steam railroad, and, as they approximate them, the duty of providing like accommodations and comforts increases. H.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

INDIANA.—Construction of Franchise—Extension Validity—Conflicting Franchise—Unoccupied Streets—Completion of Tracks—Constitutional Law—Control of Streets.

1. Acts 1861, p. 75 (Rev. St. 1894, sec. 5450; Horner's Rev. St. 1897, sec. 4143 et seq.), authorizes the organization of street railway companies, which are declared to be "corporate in perpetuity," and provides that such companies shall first obtain the city's consent to the construction of their roads through the streets of any city, and that the act shall not take from the city the exclusive control of its streets. A city passed an ordinance granting a street railroad company a franchise to operate on its streets for a stated period, and afterward extended such period. Held, that the street railway company had not, without further legislation, the right to continue the operation of its railroad on such streets after expiration of the time fixed by the ordinances.

2. Where a street railroad company incorporated under said provisions accepted an ordinance of a city granting it a franchise to operate its road on the city's streets for a stated period, and thereafter sought and secured an extension of such period, it, by so doing, in conjunction with the city, construed said act as giving it no power to occupy streets beyond the time granted by the city, and was bound by such construction.

3. The fact that a city has given a street railway company permission to construct its road on all the streets of the city, and that thereunder such company occupied a portion of the streets, does not make a franchise granted by the city to another company during the life of the former franchise invalid as to streets not occupied by the former company, since its franchise was exclusive only as to streets on which it had constructed its road, and from the time of such construction.

4. Where a city authorized a street railroad company to construct its road on all the streets of the city, and thereafter, during the life of such franchise, authorized another company to construct a street railroad system on the same streets, the rights of the two companies during the co-existence of the two charters, as to unoccupied streets, were equal, and, where one company thereafter constructed its road on any of such streets, its right as to so much thereof as was necessary for the proper operation of its cars was exclusive.

5. A contract by which a city authorized a street railroad company to construct a system of street railroads on its streets, in consideration of an annual payment to the city by such company, and its agreement to repair and clean that part of the streets occupied by its tracks, the fare being limited, and the undertakings of the company secured by sufficient indemnity, is legal and binding as between the city and the company, even though the contract may not be an advantageous one for the city.

6. After passage of two municipal ordinances, one of which granted a street-railroad franchise for a term and the other of which extended it, the city attorney advised the city that the extension was invalid. The city then granted a franchise to construct a street railroad system in the city's streets, including those occupied under the former franchise to another company, on condition that a certain portion of its system should be constructed within a specified time, the contract providing that delays caused by judicial restraint of the construction should not be counted, and delays caused by injunctions against the construction issued because of prior franchises should extend the time for completion for a stated period. The extension of the original franchise was afterward adjudged valid. Held, that the second franchise was not invalid, as granted under a mistake of law or of fact.

7. Where a street railway franchise required the company to complete its road on certain streets within a stated time, and another company, without authority so to do and without consent of the former company or of the city, forcibly took possession of such streets, and extended its road over them, the latter company could not complain that the former had failed to complete its road over such streets within the required time.

8. Act June 4, 1861, sec. 12 (Rev. St. 1894, sec. 5450; Horner's Rev. St. 1897, sec. 4143), requires street railroad companies to first obtain the city's permission to lay their tracks over said streets, and provides that nothing in the act shall deprive a city of the exclusive control of its streets. A company organized under said act was by a city given permission to construct a street railroad system on all the streets of the city. It constructed a road on a portion of such streets, and left others unoccupied. Held, that it could not thereafter take possession of, and extend its road over, other streets without further permission from the city.

9. A valid contract between a street railroad company and a city, whereby the former is given a franchise to construct a street railroad system on the streets of the latter, cannot be abrogated by an act of the legislature.

10. Acts 1897, p. 154 (Horner's Rev. St. 1897, sec 4154), amending act June 4, 1861, sec. 12, which provides that street railroad companies shall first obtain the city's consent to lay their tracks in streets, and that the act shall not deprive a city of the exclusive control of its streets, by adding that, on expiration of a street railroad franchise, the right to use the streets shall forever cease, does not annul an existing franchise to operate on city streets granted by a city under charter authority.—(City Ry. Co. vs. Citizens' St. Ry. Co. et al., 52 N. E. Rep., 157.)

LOUISIANA.—City Ordinance—Watering Street Car Tracks.

1. An ordinance of the City Council of the city of New Orleans which requires corporations operating street electric cars within the limits of the city, upon tracks laid down in the public streets thereof, to water their tracks so as to effectually lay the dust within their tracks, is a legal exercise of the police power of the city. Such an ordinance tends to promote the comfort and convenience of passengers, and the health and comfort of the inhabitants of the city.

2. It is neither indefinite nor unreasonable.—(State vs. Canal & C. R. Co., 24 So. Rep., 265.)

NEW JERSEY.—Street Railroads—Use of Streets—Notice of Location—Judicial and Legislative Acts—Constitutional Law.

A statute (3 Gen. St., p. 3237, sec. 126) authorized borough councils, upon public notice to all parties interested, to grant or to deny to a street railroad a location of its tracks conformably to its route; such grant, if made, to be upon such lawful restrictions as the interest of the public was deemed to require. Upon notice, consent to a location was given, upon the restriction, among others, "that the limit of this consent shall be twenty-five years from the acceptance of this ordinance." Subsequently, and without notice, a supplement to this ordinance was passed that eliminated the above restriction. Held: 1. The municipal act of the "location" of the tracks of a street railroad operated by the trolley system does not involve any private rights. 2. Such location is a legislative, and not a judicial, act. 3. Apart from express statutory requirement, notice is not requisite. 4. The notice required by the act is satisfied when it has been complied with. 5. Whether the action of council was in bad faith is not a judicial question.—(State —Moore et al., prosecutors—vs. West Jersey Traction Co. et al., 41 Atl. Rep., 946.)

NEW HAMPSHIRE.—Extension of Line—General Law—Public Good.

Laws 1895, c. 27, sec. 3, providing for the organization of street railway corporations by general law, and authorizing the court to determine whether the public good requires the building of a street railroad on a proposed route, has no application to an extension, by a previously and specially chartered corporation, of its road, which it was authorized by its incorporation to build.—In re Nashua Street Ry., 41 Atl. Rep., 858.)

NEW JERSEY.—Statutes—Special and Local Acts—Eminent Domain—Compensation—Street Railroads—Franchise—Certiorari —Rights of Taxpayers.

1. The act of June 13, 1898 (P. L., p. 461), entitled "An act to authorize boards of chosen freeholders to widen, straighten, grade and otherwise improve highways under their control, and to provide for the construction of street railroads thereon," is not rendered special or local by the provision that nothing in the act "shall be construed to authorize the construction of a street railroad on any public highway on which it is not lawful at present to authorize the construction of a street railroad."

2. The direction contained in said act that commissioners appointed on condemnation of lands taken for the purpose of widening, straightening, or changing the location of a highway in making their estimate and assessment of damages, "shall take into account the benefits conferred by the improvement on the remainder of any lot or tract of land partly taken," is not unconstitutional.

3. The fact that a street railroad company, with which a board of chosen freeholders has made a contract, under said act, to construct a street railroad upon a public highway under its control, has no franchise, apart from such contract, to construct or operate a street railroad upon such highway, does not give a taxpayer owning land upon the highway a standing to attack the contract. (State—Randolph et al., prosecutors—vs. Board of Chosen Freeholders of Union County et al., 41 Atl. Rep., 960.)

NEW YORK.—1. Statutes—Subject and Title—Separable Provisions.

Laws 1863, c. 361, entitled "An act to authorize the construction of a railway and tracks in the towns of West Farms and Morrisania," authorizing in the first eight sections the construction of a street railway, and in section 9 the construction of a railway to other towns, is not void in toto, as violative of Const. art. 3, sec. 16, providing that no bill shall embrace more than one subject, which shall be expressed in the title, since section 9 may be disregarded as unconstitutional, without affecting the rest of the act.

2. Same—Amendments.

Laws 1892, c. 340, amending Laws 1863, c. 361, entitled "An act to authorize the construction of a railway and tracks in" certain towns, by providing for the consolidation of companies formed thereunder, does not contain more than one subject, and that subject is sufficiently expressed in the title (Const. art. 3, sec. 16), since the amendment is within the reasonable scope of the subject contained in the title of the original act.

3. Charter—Forfeiture.

The corporate life of a company formed under Laws 1863, c. 361, providing in the first eight sections for the construction of street railways in certain towns and in section 9 for their construction in other towns, is not affected by a failure to comply with such section 9, since no authority was acquired thereunder by reason of its unconstitutionality.

4. Same—Special Privileges—Constitutional Law.

Laws 1892, c. 340, amending Laws 1863, c. 361, by exempting the corporations formed thereunder from the provisions of the general railroad act (Laws 1890, c. 565, secs. 93, 95, 98), relating to the sale of the franchise of street railroads, payment of percentage of gross receipts, and repairs of streets, is not violative of the constitution, as amended January 1, 1875, prohibiting the granting of immunities or privileges, since such provisions were conditions imposed by the Legislature, which it had power to take away.

5. Same—Construction—Consent of Municipal Authorities.

The general railroad law (Laws 1890, c. 565, sec. 91) provides that the consent of municipal authorities having "exclusive" control of any portion of a street on which it is proposed to build a railroad must be obtained before proceeding therewith. The department of public parks in the city of New York was vested with exclusive power to locate and maintain all streets, etc., until Laws 1890, c. 545, invested such power in the commissioner of street improvements in the Twenty-third and Twenty-fourth wards as to all streets therein. Held, that as the department of public parks did not have "exclusive " control of streets within the meaning of the railroad act, the commissioner has none such, and hence his consent for the construction of a railroad in such wards is unnecessary.

6. Same—Extension of Lines.

A company "extending" its lines under Laws 1892, c. 676, is not restricted to a mere prolongation of existing branches, since the term "extended" is given a broader meaning by section 90, which provides that any corporation organized since 1884, for the purpose of building or extending a street railroad or any of its branches on or along any street or avenue in any city, town or village, may do so by compliance with the article in which such section is contained.—(Bohmer vs. Haffen, 54 N. Y. Suppl., 1030.)

LIABILITY FOR NEGLIGENCE

DELAWARE.—Action on the case—Declaration—Certainty—Carriers—Injury to Passengers.

1. A declaration in "case" charged defendant with "so negligently and carelessly omitting and neglecting to use proper care and caution in running one of its cars, wherein the said plaintiff was then and there a passenger for hire, that said car ran from the rail with great force and violence," whereby plaintiff was thrown out and injured. Held, sufficiently certain.

2. A count in "case" is sufficiently definite where it charges defendant with "negligently and carelessly running two cars, upon one of which the said plaintiff was then riding as a passenger for hire, upon a certain track, which was then and there, through the negligence and carelessness of the said defendant, improper and

unsafe," whereby the car was thrown from the track, and plaintiff thereby thrown to the ground and injured.

3. A count in "case," which charges defendant with "so negligently and carelessly running a certain car in which the plaintiff was then and there a passenger for hire, and was then riding, that the said car jumped from the track," thereby causing the plaintiff's injury, is sufficiently certain.

4. A declaration in "case" charged defendant with "so negligently and carelessly operating a certain electric car, which was then and there running for the carriage of persons for hire, that thereby the said plaintiff, who was then and there a passenger on said car, was, through the negligence and carelessness of the said defendant as aforesaid," thrown from the car and injured. Held, insufficient, since the statement of facts admits of almost any proof to sustain it.—(King vs. Wilmington & N. C. Elec. Ry. Co., 41 Atl. Rep., 975.)

MINNESOTA.—Injury to Person on Track—Evidence—Question for Jury.

The plaintiff sued for personal injuries received while on defendant's track in a public street, and, against defendant's objection introduced in evidence a special rule of the defendant street-railway company intended for the guidance of its motorman, which provided that "he must keep a sharp lookout to avoid running into pedestrians and vehicles, especially at cross streets. While the car is in motion, the responsibility for safe running rests with him. * * * He will be held responsible for any damage arising from negligence." Plaintiff did not know of the existence of this rule, nor was there any evidence showing how long it had existed. Held, error; that the rule imposed a higher degree of care on the motoneer than the law required, that the jury might have understood that this rule imposed upon him and the defendant an extraordinary degree of care as to travelers on defendant's track, whereas the law imposes only a reasonable degree of care and vigilance in such cases. Held, also, that there was sufficient evidence to justify the trial court in permitting the question of the defendant's negligence and the plaintiff's contributory negligence to go to the jury.—(Isaacson vs. Duluth St. Ry. Co., 77 N. W. Rep., 433.)

NEW JERSEY.—Expert Evidence—Question for Jury.

1. The opinion of an expert witness as to the cause of an accident is incompetent when it is based upon the existence of certain facts and conditions at the time of the accident, of which he has no personal knowledge, and has not heard all the evidence in the case, unless the opinion is elicited by a question entirely hypothetical in form.

2. The opinion of a witness, that the kind of block signals used on a trolley road are not such as to insure reasonable safety to the employees operating the cars of that road, is incompetent and irrelevant; that conclusion being a question for the jury alone to determine from all the evidence in the case.—(Bergen County Traction Co. vs. Bliss, 41 Atl. Rep., 837.)

NEW YORK.—Personal Injuries—Excessive Damages.

A verdict of $3,750 is not excessive for injuries to a healthy woman, fifty-five years of age, which bruised and sprained her, and confined her to her house for two or three months on her physician's advice, and caused permanent prolapsus uteri and congestion, necessitating the wearing of a pessary.—(Rippe vs. Metropol. St. Ry. Co., 54 N. Y. Suppl., 958.)

NEW YORK.—Injury to Person on Track—Contributory Negligence.

Where plaintiff, on a dark night, was driving along the track of a street railway on which its cars would approach from his rear, and there was no room for him to drive outside of its double tracks, and he was familiar with both the street and the street railway's method of operating its cars thereon, in an action for personal injuries he is bound to show affirmatively that he was exercising that reasonable care which the obvious dangers of his situation demanded, as there is no inference that he was free from contributory negligence, in the absence of evidence that he ever looked back or listened for the approach of the cars.—(Johnson vs. Brooklyn Heights R. Co., 54 N. Y. Suppl., 547.)

In an action for personal injuries, caused by negligence, the trial court has discretionary power to reduce a verdict as being excessive.

2. Same—Appeal.

In an action for personal injuries, the evidence showed that plaintiff was a boy eighteen months old, and that his leg was amputated above the knee. The verdict was $15,941.25. The trial judge, in his opinion, stated that the amputation was below the knee, and that, if he could exercise any discretion, he would reduce the verdict, but erroneously decided that he had no such discretion. Held, that the verdict was not clearly excessive.—(Kalfur vs. Broadway Ferry & M. Ave. R. Co., 54 N. Y. Suppl., 503.)

NEW YORK.—1. Review—Conflicting Evidence—Finding of Jury.

The verdict of a jury on conflicting evidence will not be disturbed.

2. Warning from Approaching Car.

Workmen repairing a street about a street-car track are entitled to more warning of an approaching car than the noise it makes in running.

3. Same—Collision with Street Car—Contributory Negligence—Question for Jury.

Plaintiff was rightfully at work on defendant's street-car track, repairing the street, when he was struck by a car whose bell gave him no warning of its approach, but which he could have seen, if he had looked, at a distance of 1,500 feet. Before stooping down to pour tar on the paving, he looked and saw no car in sight. As the tar had to be poured while very hot, it could not be long delayed, and to do so he had to bend over. He swore he did not know the car was near him until he was struck. Held, that the negligence of plaintiff, in omitting to look after he began to empty his bucket, was for the jury.

4. Instructions—Harmless Error.

A refusal to give a specific charge, where the court had already charged correctly the proposition involved, was harmless error.—(Lewis vs. Binghamton R. Co., 54 N. Y. Suppl., 452.)

NEW YORK.—Negligence of Motorman—Child on Track—Burden of Proof.

In an action against an electric street railway for killing a six-year-old boy, the negligence alleged was the omission of the motorman to stop the car before striking the child. The car was running at a speed not to exceed the prohibited rate of more than 12 miles an hour. Plaintiff's evidence showed that, when the car was 71 feet from where the boy was struck, the boy had passed onto the outside rail, and was running directly across the track, but was struck when he had nearly reached the inside rail. The rails were not quite five feet apart, and, if plaintiff's evidence was true, the car traveled more than 17 times as fast as the boy, which would make its speed at least 34 miles to the hour (assuming the boy was running at the rate of 2 miles an hour), which was incredible, in view of the finding that it was not going faster than 12 miles per hour. The motorman testified that when he first saw the boy he was running diagonally by the car, and, "quick as a shot," ran and fell over the rail, and that he immediately lowered the fender and applied the brakes, but to no avail. There was no evidence that the motorman saw the boy, or heard any warning concerning him, except his own testimony. Held, that a verdict for plaintiff should be reversed, since it was as reasonable to infer the motorman was not negligent, as the contrary, and the burden of proof was on plaintiff.—(White vs. Albany Ry., 54 N. Y. Suppl., 445.)

Decision on Cast Welded Rail Joint Patent

In the case of the Falk Manufacturing Company vs. the Missouri Railroad Company and the American Improved Rail Joint Company, which has been pending since July, 1897, an opinion was filed on Jan. 10 by Judges Adams and Sanborn, of the United States Circuit Court at St. Louis. In this opinion the Court finds that while the Falk company's patent sued upon (No. 545,040) has five claims, yet each of them might be said to be practically based upon the following steps, viz.:

1. Cleaning the abutting rails for a short distance from the ends.
2. Heating such cleaned rail ends.
3. Adjusting a mold around such rail ends, and
4. Pouring molten metal into the molds.

After commenting upon the result obtained, in the way of securing what are known as "continuous rails," the Court says:

"In our opinion, without entering into any detailed analysis of the evidence bearing on the state of the art, consisting generally of publications, technical works, mechanical operations, individual experiences, common knowledge and divers patents—all of which have been carefully considered—the efforts of the patentee, as disclosed by this patent, belong to the domain of mechanical skill and not to the domain of invention."

The Court further holds that the Norris patent of 1851 and the Stephenson patent of 1831 are anticipatory of the Falk patent. The Falk company contends, however, that these patents describe inventions which were never tried in practice, and, therefore, do not hold.

It is understood that the Falk company will appeal this decision at once, carrying the matter to the highest courts if necessary, but it holds that even should the patent be finally defeated, it does not follow that its control of the cast welded joint business would be thereby weakened, since it holds numerous other process or detail patents, without infringing upon which it is claimed that no successful cast welded joint can be made.

Recent Annual Reports

BOSTON ELEVATED RAILWAY COMPANY

In the first annual report of the Boston Elevated Railway Company, the directors review the history of the company from its organization in 1894 to its lease of the West End system and its leased lines, which took effect Sept. 30, 1897. The summary of the business for the complete year, ending Sept. 30, 1898, is as follows:

Gross earnings from operation		$9,179,096.35
Operating expenses		6,566,584.16
Net earnings from operation of leased lines		$2,612,512.19
Subway rental	$106,134.35	
Interest on West End funded debt	498,600.00	
Dividend on West End preferred stock, 8 per cent	512,000.00	
Dividend on West End common stock, 7 per cent	635,950.00	
Dividend on Somerville H. R. Company's stock, 6 per cent	9,180.00	
Taxes on West End property	435,860 44	
Total payments under lease of West End St. Ry. Co.		$2,197,724.79
		$414,787.40
Add interest on special deposits		78,156.59
		$492,943.99
Taxes, Boston Elevated Railway Co.	$86,049.74	
Compensation tax under agreement with Commonwealth, act of 1897	80,317.09	
		166,366.83
Balance		$326,577.16
Interest paid to holders of Boston Elevated Railway Company, receipts, Aug. 15, 1898, 2¼ per cent on amount actually paid in		112,500.00
Surplus for the year		$214,077.16

The report shows that work on the plans of the new elevated line has been vigorously prosecuted, and within a short time a large proportion of the structure will be put under contract. Foundations will be begun in the opening of the spring of 1899. The plans for the terminal stations at Roxbury and Charlestown have been completed, and a large part of the required land has been taken by eminent domain or purchased. George A. Kimball is the company's chief engineer of elevated lines, and since the report was issued John Lundie has been appointed consulting engineer, particularly with a view to decisions of car service and operation.

The company's general balance sheet shows as its large items a capital stock of $5,000,000, and a lease account, West End Street Railway Company, of $1,362,023 in liabilities, and in assets, cash on hand and in bank, $5,532,445, and West End Street Railway Company and Somerville Horse Railroad Company bond, property and open accounts amounting to $1,932,048. The company carried 209,561,175 passengers during the year, of which 28,239,880 were free transfer passengers. The car mileage was 32,379,445, and the receipts per total passenger were 4.279 cents.

THE COLUMBUS STREET RAILWAY COMPANY

The annual report of the Columbus Street Railway Company for the year ending Dec. 31, 1898, shows the following interesting figures:

EARNINGS AND OPERATING EXPENSES IN DETAIL

	1897.	1898.
Gross earnings	$605,921	$680,173
Operating expenses	286,874	327,692
Earnings from operation	$319,047	$352,481
Miscellaneous earnings	5,397	8,860
Total receipts—all sources	$324,444	$361,340
Fixed charges	200,151	205,964
	$124,293	$155,376

EARNINGS AND EXPENSES PER CAR MILE

	1897.	1898.
Earnings	$.168	$.183
Expenses—		
Maintenance of way	.006	.01
Maintenance of equipment	.007	.008
Conducting transportation	.046	.046
Power	.007	.007
General expenses	.013	.016
Total expenses	$.079	$.087
Net earings	.089	.096

The balance sheet shows in liabilities, capital stock, $3,000,000; bonded debt, $3,000,000; Crosstown bonds, guaranteed, $572,000; reconstruction reserve, $28,531; current liabilities, $192,301. In assets are plant, property and franchises, construction and equipment, $6,346,755; Crosstown lease and ownership, $572,000; park construction and equipment, $33,115; current assets, $38,393; prepaid accounts and sinking fund, $43,594. The balance sheet surplus is $231,025.

CHICAGO CITY RAILWAY COMPANY

The annual report for the year ending December 31, 1898, including the following figures of operation, is as follows:

	1897.	1898.
Gross earnings	$4,816,516	$4,832,806
Operating expenses and taxes	2,908,982	2,926,490
Net earnings	$1,907,534	$1,906,316
Interest	207,877	207,877
Dividends	1,440,000	1,440,000
Balance for the year	$259,657	$258,439
Depreciation, etc	50,000	90,000
Per cent operating expenses	60.84	60.97
Passengers carried, cable	41,444,646	38,482,628
Passengers carried, horse	691,051	477,313
Passengers carried, electric	53,485,425	57,032,173
Miles run, cable	12,562,610	11,678,020
Miles run, horse	198,860	143,900
Miles run, electric	11,616,530	12,563,380

At the annual meeting, Joseph Leiter, formerly second vice-president, was made first vice-president, and D. G. Hamilton was made second vice-president; other officers and directors remained unchanged. An increase of $2,000,000 in capital stock was authorized.

NORTH CHICAGO STREET RAILROAD COMPANY

The annual report for the year ending December 31, 1898, includes the following figures:

	1897.	1898.
Passengers carried	56,354,147	58,422,077
Miles run	10,644,270	10,916,737
Receipts from—		
Cable lines	$1,421,848	$1,448,652
Electric lines	1,375,638	1,456,908
Horse lines	20,911	15,865
Total	$2,818,398	$2,921,425
Other income	93,153	93,898
Total income	$2,911,551	$3,015,323
Operating expenses	1,319,926	1,390,681
Net earnings	$1,591,625	$1,624,642
Interest, rentals, taxes, etc	636,462	543,666
Dividend paid, 12 per cent	791,943	870,957
Balance, surplus	$163,220	$210,019

WEST CHICAGO STREET RAILROAD COMPANY

The annual report for the year ending Dec. 31, 1898, includes the following figures:

	1897.	1898.
Passengers carried	78,594,932	80,600,505
Receipts from—		
Cable lines	$1,451,984	$1,427,622
Electric lines	2,382,768	2,539,204
Horse lines	13,859	11,634
Advertising, etc	51,307	53,443
Gross earnings	$3,899,918	$4,031,903
Operating expenses	1,929,664	2,017,946
Net earnings	$1,970,254	$2,013,957
Fixed charges—		
Rental of leased roads	$736,465	.....
Coupon interest	.....	$1,198,000
Other interest and taxes	399,720	.....
Dividends paid	791,340	791,340
Surplus for year	$42,729	$24,617

NORTHWESTERN ELEVATED RAILROAD COMPANY

At the annual meeting of the Columbia Construction Company, which has a general contract for building the Northwestern Elevated Railroad, President George A. Yuille announced that in December an arrangement was completed with Blair & Company, of New York, whereby the Northwestern Elevated Railroad Company had secured a loan of $4,500,000 to pay off the outstanding obligations incurred for labor, material and right of way, and to complete the road and put it in operation. In order to secure this loan, the capital stock of the Northwestern Company had been reduced from $15,000,000 to $10,000,000, of which $5,000,000 was in common stock and $5,000,000 in preferred, and the authorized bond issue was reduced from $15,000,000 to $5,000,000. It was agreed that the parties making the loan would receive as a bonus $1,000,000 of the preferred stock and $1,000,000 of the common stock, leaving for the Columbia Construction Company on the final completion of the road and payment of the loan $4,000,000 of preferred and $4,000,000 of common stock.

LAKE STREET ELEVATED RAILROAD COMPANY

The annual report for the year ending Dec. 31, 1898, includes the following figures:

	1897.	1898.
Passengers carried	11,229,590	12,391,020
Gross earnings	$579,961	$633,403
Operating expenses	329,124	324,947
Net revenue	$250,837	$308,456
Taxes	18,612	13,849
Interest on bonds	227,605	221,677
Miscellaneous interest	29,874	37,667
Loop rental	15,707	61,954
Total	$291,798	$335,147
Extraordinary expenses	31,880	.....
Deficit for year	72,841	26,691

NEW ORLEANS TRACTION COMPANY

The annual report for the year ending Nov. 30, 1898, is as follows:

	1897.	1898.
Gross earnings	$1,239,256	$1,311,365
Operating expenses	847,833	801,971
Net earnings	$391,423	$509,394
Other income		39,150
Total		$548,544
Fixed charges		380,013
Balance		$168,531
Dividends, 5 per cent on preferred stock		125,000
Surplus		$43,531

SOUTH SIDE ELEVATED RAILROAD COMPANY

In view of the equipment of the South Side Elevated Railroad Company, of Chicago, by a novel and hitherto untried electric system, the Sprague multiple unit system, the following abstract of President Carter's report to the stockholders, on January 26, will be of peculiar interest:

The company's road was operated by steam power from Jan. 1 to Apr. 20. In that time the operating expenses ranged from 80.8 to 84.7 per cent of the gross receipts. From Apr. 20 to July 27, the operation was partly by steam and partly by electricity, the change being gradual and necessarily involving the additional expense of maintaining two systems. In these months the operating expenses ranged from 70.2 to 75.7 per cent of the gross receipts. Since July 27, 1898, the operation has been entirely by electrical power, and the percentage of expenses to earnings steadily decreased from 63.7 per cent to 55 per cent in December.

All of the above figures include a loop rental of one-half cent per passenger. Not including the loop rental, but including all other operating expenses, taxes, car licenses, etc., the road was operated in October for 47 per cent, in November for 47.7 per cent, and in December for 45.4 per cent. Expenses have not only been on an increasing ratio, but gross earnings have been steadily increasing.

If the entire year be divided into two periods of six months each, the contrast between steam and electric operation becomes more striking. The number of passengers carried during each period is approximately the same. The net earnings applicable to interest and dividends were for the first half of the year (steam and mixed operation) $98,973, and for the second half with electrical operation (mixed in July) were $196,933, or almost double the earnings of the first six months.

The net earnings applicable to dividends on stock during the last six months were at the rate of 3½ per cent per annum, as against but 1 per cent per annum for 1897.

At the time the change in power was undertaken, the road needed about ninety cars to transact its business, and 120 seemed an ample equipment on the new basis, but with growing patronage it has become necessary to increase the total equipment to 180 cars, of which 120 will be motor cars and sixty trail cars.

The operating expenses of the power plant, based on maximum power required of 8,000 h.p. for about four hours each day in the winter months, is about $8 per h.p. per annum, and adding to the above general expenses 10 per cent depreciation, interest, insurance and taxes, the total cost per maximum h.p. per annum does not exceed $15.

Mr. Carter speaks of the Sprague multiple unit system as follows:

"At the time of the last annual meeting we reported that the test of the train equipped by Mr. Sprague, made on the Metropolitan Elevated road, was satisfactory. We began using electric cars in April, had sixty-seven in operation in May, and gradually increased the number until July, when they finally superseded the steam trains. We had minor difficulties to contend with which were met and solved. None of them resulted in injury to any passenger, and none of them involving the control of the train, which has always been complete. I am assured that the difficulties and annoyances were not so great as they were in installing the excellent steam locomotives which they displaced. We believe that the Sprague multiple-unit system has fulfilled expectations. Exhaustive tests have proved the economy of rapid acceleration and long coasting. A schedule speed of 15 miles per hour is easily maintained, and time lost is easily made up. If needed, in order to meet competition, your company has the ability to increase the speed to 20 miles an hour.

"The reliability of the equipment has been fully tested this winter, when 150 cars, all we had, were in daily operation (Sundays excepted) for many weeks.

"We have not been in electrical operation long enough to definitely determine the cost of maintenance, but we have sufficient data to confidently state that it will be low, as low as any other line doing equivalent service, and lower than many surface lines with 18-ft. single truck cars. The advantage of this flexible system on crowded days, for switching and changing the length of trains, is apparent."

The use of storage batteries is also referred to at some length in President Carter's report, and the statement is made that their use is a success, certainly in the matter of keeping up voltage and enabling the road to operate more cars, to furnish increased facilities to patrons and to prevent damage to power house machines under a sudden demand for increased power, while it is claimed, though not as yet fully demonstrated, that the cost of power production is also cheapened.

Another Consolidation in Baltimore

An agreement has been signed whereby a syndicate, headed by Alexander Brown & Sons, secures the right to purchase the entire capital stock of the Baltimore Consolidated Railway by March 30, payment to be made by April 30, and the price to be $37.50 per $25 share. Stockholders may elect to take cash or the securities of the proposed new company. This syndicate is the same one that purchased the capital stock of the Baltimore City Passenger Railway last month, and the agreement probably means the consolidation of practically the entire street railway system of Baltimore.

Uniforms for Employees

Hackett, Carhart & Company, of New York, one of the oldest and most reliable clothiers in the country, are now making a specialty of supplying uniforms of all kinds for employees and officials, and are paying particular attention to the requirements of employees on street railways and steam roads. This company has not been content with following the old methods of turning out this class of work, but has introduced a new and improved system whereby it is enabled to furnish high grade uniforms at reasonable prices. It cordially requests superintendents and purchasing agents to send for samples and estimates.

Chicago Street Railway Franchises

The following official statement has recently been issued by Charles T. Yerkes, relating to the Chicago street railway properties:

There is considerable misunderstanding regarding the legislative position of Chicago's street railway franchises. The impression which prevails in Wall Street is that it is necessary to secure an extension of franchises, before 1903, or the various roads will pass to the control of the city. It is also claimed that a repeal of the Allen law becomes necessary and a new measure adopted by the General Assembly of the State of Illinois before there can be any renewal of franchises, inasmuch as the City Council of Chicago has practically failed to extend the street railway franchises for fifty years under the present Allen law.

These premises are wrong. The street railways of Chicago are nearly all operated under 99-year franchises; at least all of the important lines, which include the Chicago City Railway Company, operating on the South Side, and the so-called Yerkes properties, operating on the West and North Sides. This disposes of the socialistic talk so recently rampant in Chicago respecting probable municipal ownership.

The franchise position of the street railways is briefly as follows:

Under authority granted by the State, the Chicago City Railway Company was granted a 99-year franchise from Feb. 14, 1859. The Yerkes properties on the North and West Sides hold franchises for 99 years; that on the North Side dating from 1886 and that on the West Side dating from 1863. Under the terms of these 99-year franchises it was provided that the City Council of Chicago should grant ordinances in periods of 20 years, permitting the use of and designating streets under specific terms. The first 20 years was passed without feature, and not until 1883 was there any trouble regarding the extension of time for the use of the streets. At that time the elder Carter H. Harrison, then Mayor of Chicago, saw fit to make political capital out of the street railway and demanded that a compensation be exacted for a renewal of the ordinances granting the use of certain streets already occupied and others which there was a desire to occupy.

In 1883 there was need for improvement in the street railway systems of Chicago, and it was not deemed wise to antagonize investors by precipitating a legal fight over the question of authority to declare occupied streets vacant. It was also important that new streets be acquired. In consequence the street railway companies agreed voluntarily to pay the city $50 per car per year for an extension of ordinances for another 20 years. It is notable that the Mayor, the elder Harrison, publicly stated that he had invariably been advised by eminent counsel that the city had no authority to displace the street railway companies who were in possession of streets and that the 99-year franchises could not be abrogated.

So far as the legal position is concerned there is no change at present. The same reasons exist to-day, however, for a peaceable solution of the franchise quesion that did in 1883. It is not desired to disturb the confidence of investors by what might be an almost endless litigation over the authority of the city to abrogate the use of streets in which cars are now operated. It was with this end in view that the Humphrey's bill was proposed and a compromise reached, which resulted in the Allen bill. If 50-year ordinances could have been obtained from the city under this bill there would have been no danger of a long legal fight.

Since it has been found that there is little hope of securing any results from the existing state of things in the Chicago City Council, recourse is to be had to the State Assembly, which convenes in Springfield, Jan. 4. There is a rabid demand for the repeal of the Allen law, but this is not likely to occur, but, instead, some sort of amendments made whereby a compromise is had. A number of bills have already been prepared, but it is yet much too early to say what the precise nature of the compromise will be.

Change in the General Electric Company

John McGhie has resigned his position as manager of the advertising department of the General Electric Company, in order to undertake important and responsible work with the "American Machinist." His headquarters will hereafter be at Cleveland, Ohio, to which city he will move his family from Montclair, N. J. Mr. McGhie's management of the General Electric Company's advertising business has been able and painstaking to an unusual degree, and the record which he leaves behind him is one with which both his principals and himself have every reason to be satisfied.

W. J. Fransioli, formerly general manager of the Manhattan Railroad Company, of New York, has associated himself with the American Air Power Company.

NEWS OF THE MONTH

The Boston & Albany Railroad is trying an interesting experiment which should also be of interest to street railway managers. This consists of sprinkling its roadbed with non-flamable and practically odorless oil for the purpose of freeing the tracks from dust. In addition to removing the dust the oil sprinkling keeps the rain from washing away the roadbed, destroys vegetation, prevents frost from penetrating and injuring the roadbed, lessens the noise of trains, and by preventing dust greatly reduces the danger of hotboxes. It costs $150 a mile to sprinkle the roadbed, and one sprinkling a year is sufficient.

The Boston Elevated Railway Company has 456 miles of overhead electric feeder lines, 63 miles of underground electric feeder lines, 133 miles of underground conduit duct, 68 miles of underground electric return lines and 2.8 miles of submarine cables. It owns 3370 electric motors, 1274 electric box cars, of which 884 are twenty-five foot bodies, and 1292 electric open cars, of which 724 are nine and ten bench, 11 mail cars, 3370 electric motors and 236 cars and electric snow plows.

The recent stoppage of traffic on the underground electric conduit road on Sixth Avenue, New York, for several hours, was due not to flooding of the conduit, as has been erroneously stated in the press, but to the overloading and consequent burning in two of a main feed wire furnishing current to one of the sections of the line. This line is now being operated in a somewhat temporary way pending the completion of the new 70,000 h.p. station, and the final feed wire system to be installed in connection therewith.

A 15-ft. flywheel in the Birmingham Traction Company's plant at Pittsburgh, Pa., burst about 10 o'clock on the night of Dec. 11, and did considerable damage. A 300-h.p. engine was wrecked and a portion of the building suffered considerable damage. No one was hurt.

The Rochester (N. Y.) Railway Company suffered serious loss on Jan. 1 from fire, which destroyed its State Street barns, and twenty-one cars that could not be saved in time. The cause of the fire is unknown.

The following bills have been introduced in the Senate at Albany, N. Y.: One requiring all street cars to be equipped with "automatic, trip and drop front fenders" (violators are punishable by a fine of $100 for each day a car is run without such fenders; also one providing that whenever any street car is delayed for five or more minutes, passengers shall receive transfer tickets good at any time for a continuous ride on any line of the company. Violation renders companies liable for damages in $250, to be recovered in civil action by passengers to whom transfer is refused.

The street railway company at Marinette, Wis., has decided to place heavy curtains on both ends of its car to protect the motormen.

All the surface and elevated railroad companies in Greater New York were compelled by the city authorities during the recent grippe scare to thoroughly fumigate all their cars, including all mats, matting, rugs, etc., used therein.

President Gaston, of the Boston Elevated Railroad, states that for the year Oct. 1, 1898, to Oct. 1, 1899, the number of transfers issued by the Boston Elevated Railroad shows a larger increase than for any year in the history of transportation in Boston. In the past eight years the number of passengers carried have increased 52 per cent, while free transfers have increased 251 per cent. During the last fiscal year the number of passengers increased 5 per cent, while transfers increased over 19 per cent.

A suit was recently brought against the Rochester Railway Company for five cents, this being the amount the plaintiff claimed was due him as change for ten cents which he handed a conductor on the defendant's road. The conductor swore that the plaintiff gave him five cents instead of ten, and as he was able to bring witnesses to prove this, the suit was decided against the plaintiff, who had to pay the costs.

The Bloomington (Ill.) City Railway Company, on Dec. 17, turned the receipts of its Normal line over to the Normal Library Association, and the cars were in charge of the young ladies of that association as conductors. Nearly $200 was added to the funds of the library as a result of the day's operation. A chaperon rode on each car to assist the young ladies.

It is stated that thirty employees of the Newport News & Old Point Railway & Electric Company, formerly the Newport News, Hampton & Old Point Railway Company, divided $16,000 between them recently, the gift of J. S. Darling, president of the old company, and his son. Individual amounts were based on time of service. One man received a check for $1,000, and several conductors received $750 each.

The Columbus (Ohio) Street Railway Company is considering the advisability of placing the weather forecasts printed on neat cards in all its cars. The local weather station will probably furnish the printed cards daily, and it is believed this departure will add to the popularity of the street railway lines.

Definite plans are said to be under active consideration at present for a reorganization of the Kings County Elevated Railroad Company, with a view to its consolidation with the Brooklyn Elevated Railroad Company. The Kings County reorganization committee has recently held several meetings, and a plan will, it is said, before long be issued to stock and bond holders of the road. It is stated new securities will soon be issued for equipping the road with electricity, etc.

The Rochester (N. Y.) Railway Company has adopted a novel carrier for cigars, and will place a number of them in its cars. The device is made of nickeled tin, and has places for four cigars, the idea being that when a man boards a car with a lighted cigar which he desires to save he can place it in the carrier until he leaves the car.

The combination open and closed cars which have been in operation on the lines of the Nassau Electric Railway of Brooklyn, and which were described in the STREET RAILWAY JOURNAL for November, 1898, have not been very popular with the public. To overcome some of the objections raised, the company has made a number of changes in five of the cars, and if it is found advisable the changes will be made in all of the combination cars on the road. The principal improvement consists of four levers placed on the rear platform, by which the conductor can open any one of the side doors without leaving his place. Both bell ropes have been placed on the outside of the car, so that conductors will not have to open a door to ring up a fare or give the motorman the signal to go ahead or stop. The loud noise caused by the slamming shut of the side doors is also done away with on the improved cars by the insertion of a rubber strip in the door jamb, while a rubber knob prevents a similar noise when the doors are opened. In addition to these improvements a rubber matting about half an inch thick has been placed along the side step of the car to keep the passengers and conductors from slipping in stormy weather, and the upright iron bars used as hand rails have been incased in rubber. A gutter has been added to the side of the car also to keep the rain and water from dripping down upon the conductor as he passes along the step. The gutter runs toward the rear of the car and empties the water over the rear platform.

The lines of the East Liverpool Railway Company, of East Liverpool, Ohio, were tied up for several hours recently on account of a strike of the employees. The trouble was caused by the discharge of a motorman who was a member of the motormen's union, but was finally settled by a compromise, and the men returned to work.

The Syracuse Rapid Transit Railway Company has voluntarily placed in operation a new scale of wages for motormen and conductors. Since 1896 the pay of the men has been 13½ cents per hour for the first twelve months, 15 cents for the next twelve months and 16½ cents after that. From now on the pay for the first three months in service will be 14 cents an hour, for the next three months 14½ cents, for the next six, 15 cents, for the next six, 15½ cents, for the next six, 16 cents, and for the next six and thereafter the men will receive 16½ cents an hour. This new schedule will be particularly advantageous to the new men, as under it the average pay per hour for the first two years will be 15 cents, instead of 14 cents as formerly. Men who have been employed by the company for more than two years will be given the best runs. In addition to the above increase in wages the company has notified all its motormen that they will be furnished fur overcoats at the company's expense. The coats are to be worn only during the hours of duty, and are to be returned to the station foremen at the end of the day's run.

The annual report to the Legislature of the New York Board of Railroad Commissioners was made on Jan. 4, and contained the following general statistics:

Year ending June 30.	1897.	1898.
Capital stock	$126,978,482 50	$132,844,303 33
Funded debt	104,823,698 57	130,179,166 90
Unfunded debt	23,254,380 39	31,806,542 42
Cost of road and equipment	221,665,039 63	233,635,396 51
Gross earnings from operation	29,911,428 02	31,884,384 20
Operating expenses	18,117,799 48	19,153,716 55
Net earnings from operation	11,793,628 54	12,730,667 65
Income from other sources	1,262,358 95	1,457,501 55
Gross income from all sources	13,055,987 49	14,188,169 20
Taxes and miscellaneous	1,408,719 61	1,459,469 96
*Interest paid and accrued	5,392,037 45	6,022,776 79
*Dividends	5,387,164 96	5,799,359 32
Surplus for the year	604,506 70	631,007 34

* Includes respectively interest and dividends paid by lessors from rentals received from lessees as follows:

	1897.	1898.
Interest	$1,549,001 67	$1,666,068 34
Dividends	2,581,054 96	2,729,894 32

The Niagara Falls & Lewiston Railway (the Great Gorge line) operating down the bluff at Niagara Falls, carried 288,791 passengers during the year ending June 30, 1898, and ran 163,013 passenger car miles. Its average operating earnings per passenger were 25.4 cents, and its operating expenses 7.31 cents. Its total receipts, however, amounted to 29.64 cents per passenger, of which all but .15 cents was consumed in paying operating expenses and fixed charges. The cost of operation per car mile was 17.25 cents, and the total receipts per car mile were 52.44 cents. The total operating expenses and fixed charges on this line were 51.98 cents per car mile.

An incident showing the fallacy of some of the arguments put forth by the advocates of municipal ownership of street railways occurred in St. Joseph recently, when the St. Joseph & Benton Harbor Railway & Light Company secured the contract to light and heat the court house and jail at St. Joseph for three years for $3,900. The county formerly did this work itself, and paid over $6,000 for the years 1896, 1897 and 1898. The building committee refused to give W. Worth Bean, president of the above company, the contract for the lighting in 1899, but by persistent effort he finally secured it by showing actual results. The citizens are pleased at this saving to the county.

The work of reorganizing the Metropolitan West Side Elevated Railroad Company, of Chicago, Ill., is about completed, and the company will soon be placed on a sound financial basis.

The Chicago Electric Traction Company, of Chicago, Ill., has filed a mortgage for $500,000 to the Manhattan Trust Company of New York, and John Kean for first mortgage 5 per cent thirty-year gold bonds.

The Toledo Traction Company of Toledo, Ohio, principally through the efforts of Thomas H. McLean, general manager, has been able to entirely break up the labor union of its employees, and the leaders of the local union, which is known as Division No. 49 of the Amalgamated Association of Street Railway Employees of America, have surrendered its charter to the head association.

The Union Traction Company, of Rutherford, N. J., was sold at receiver's sale on Jan. 27, to the reorganization committee representing 90 per cent of the bondholders. The purchase price was $20,000 over the indebtedness, which, as shown by the receiver's report, was $852,000.

A serious head-on collision occurred on the line of the Worcester & Suburban Street Railway on Dec. 22, near Leicester, Mass. A very heavy fog hung over the tracks at the time, and an inbound car ran into an out-bound car that should have waited at the turnout. Neither of the motormen could see the other car until it was too late to avert the accident. Two persons were killed and several injured.

It is stated that inquiries from China for railroad material and electrical equipment of American make are very numerous, and there are prospects of extensive deals in these branches in the spring.

Vice-President Webb, of the Baltimore & Northern City Railway Company, which company has recently purchased the capital stock of the Baltimore City Passenger Railway Company, and the Baltimore, Middle River & Sparrow's Point Electric Railway Company, has made the following statement: "The property is in the hands of people who are financially able to carry out any contracts they may undertake, and it may also be assumed that they are not only able but determined to vigorously protect their interests from attacks by any competitor. While the syndicate has not yet fully developed its plans, the field has been sufficiently canvassed to warrant the statement that certain territory will be entered that will add largely to the revenue of the combined lines. As the purchase was made for investment purposes, it will, of course, be the general policy to fully develop the earning capacities of the three roads, and one of the most effective ways of doing this is to give every possible convenience to the public. The City Passenger system, as is well known, lacked suburban lines, and the consolidation with the Baltimore & Northern and the Middle River road will not only give to the new system a suburban mileage of fifty-three miles, but puts the new company in a position to acquire additional territory at any future time."

It was announced last month that the Fifth Avenue Stage Line, New York, had been purchased by the Third Avenue Railroad Company, and that automobile electric carriages would be substituted for the horse stages.

While sawing down a dead tree in Brooklyn, recently, a laborer was stricken insensible by an electric shock. The tree had been used for supporting a span wire of the trolley road, and in some way the insulation had become worn.

The Third Avenue Railroad Employees' Mutual Relief Association of New York gave its annual entertainment and reception at the Lexington Opera House, on Jan. 27. A very excellent vaudeville entertainment was given, after which dancing was indulged in. This relief association is one of the most prosperous in the country, its success being largely due to the interest taken in it by the officials of the Third Avenue Railroad Company.

The Northwestern Electrical Association held its annual convention in Milwaukee, Wis., Jan. 18, 19 and 20. The meetings were well attended and the papers and discussions were pronounced most interesting and valuable by all present.

The National Electrical Light Association will hold its twenty-second meeting in New York, May 23, 24 and 25, 1899. The headquarters of the association will be at the Murray Hill Hotel, where accommodations can be had on the American plan at $3.50 and upward per day, and on the European plan at $1.50 and up. The Electrical Exhibition Company will hold its annual electrical show at Madison Square Garden, under the auspices of this association during May.

The Manufacture of Special Work

The New York Switch & Crossing Company has made a number of additions to its works at Hoboken, N. J., during the past year, and is now better able than ever to supply all classes of special work. Among the new tools installed by the company is a large 16 ft. planer with a range of 36 ins. × 18 ins., used for planing switches, a new cold saw for cutting the deepest girder rails, several radical drills and smaller planers, a punch for punching a 1½-in. hole through 1-in. iron, an electric jib crane, etc.

The company reports doing an excellent business during the past year, and among other street railway companies supplied by it with special work were the Union Railway Company, of New York; Brooklyn Heights Railroad Company, and Coney Island & Brooklyn Railroad Company, of Brooklyn, the Consolidated Traction Company, and the North Hudson County Railway, of Jersey City and Hoboken, and the Hartford Street Railway, of Hartford, Conn.

The New York Switch & Crossing Company has also turned out a large amount of steam railroad and construction railroad parts, notably for the J. P. McDonald Company and for the United States Government railroads in the Brooklyn Navy Yard and Indian Head Proving Grounds. The company has also supplied a large amount of special work for export mostly of the T rail type.

New Interests in Compressed Air as a Motive Power

Late in December and early in January, there were organized several companies with large capital, intending to use compressed air for various purposes, and in view of the financial standing and importance of the interests involved in this movement to place upon the market a new motive power, it is advisable to explain the status of the parent and affiliated companies.

The American Air Power Company, of New York, was organized in January, 1898, as a consolidation of the American Air Power Company, of New Jersey, the General Compressed Air Company, of New Jersey, and the Compressed Air Power Company, of New York. The first two companies had been engaged in developing the Hardie motor, and the third the Hoadley-Knight motor. The capital stock of the consolidation company was $7,000,000, and A. A. McLeod, formerly president of the Reading Railroad system, became the company's president.

In January, 1899, the International Air Power Company, of New Jersey, was formed with a capital of $7,000,000. Later on it was announced that this company had secured from the American Air Power Company exclusive rights for all its letters patent in foreign countries; rights for all patents in North and South America, except those bearing directly upon street railway traction, were reserved by the American Air Power Company. The principal stockholders of the International Air Power Company are said to include some of the strongest and best known street railway and other capitalists in America.

Following the organization of this second company is that of the New York Auto Truck Company for $10,000,000, and the Chicago Auto Truck Company, while a similar company for Philadelphia is to be organized. The International Air Power Company will retain large holdings of stock in these three companies and in others which will be formed in different cities, and will manufacture and sell to them complete compressed air trucks intended to do a general city trucking business, replacing and gradually driving from the field the present horse trucks.

The directors of the New York Auto Truck Company are J. H. Hoadley, Richard Croker, ex-Senator Arthur P. Gorman, Robert McKinstry, Nathan Strauss and Lewis Nixon, owner of the Crescent Shipyards, of Elizabethport, and designer of the United States battle ships Massachusetts, Indiana and Oregon. The directors of the Chicago Auto Truck Company will include Joseph Leiter and associates.

The International Air Power Company has purchased for manufacturing purposes the works of the American Wheelock Engine Company, in Worcester, and the Rhode Island Locomotive Works, in Providence. The new auto trucks will be built at the company's Providence works, and air compressors for the auto truck business in Worcester.

The American Air Power Company is now equipping with compressed air motors and apparatus tweny cars for the Metropolitan Street Railway Company's Twenty-eighth and Twenty-ninth Streets crosstown line, and the Ingersoll Sargent Company has practically completed a four-stage compressor to furnish the necessary motive power. The compressed air power station for the Twenty-eighth and Twenty-ninth Streets line is located at the foot of West Twenty-fourth Street, and work is going on rapidly upon the engine foundations, boilers, etc., while in a small temporary shop near by, the motors are constructed.

A full description of the Hoadley-Knight motors of the American Air Power Company and of the engineering features of the four stage compression was given in the STREET RAILWAY JOURNAL for August, 1897, page 487.

Latest Progress in the Application of Storage Batteries to Electric Railways*

BY JOSEPH APPLETON

The history of the storage battery in this country is curious, and probably comprises more troubles and trials than any other branch of the electrical industry. I think it will be generally acknowledged that a storage battery "per se" should be one of the most useful adjuncts in every branch of electrical engineering, but the failures that were recorded in the earlier days proved that the storage battery was not then the commercial success those interested would have us believe. Until 1894, the use of storage batteries in this country proved most disastrous to all concerned. The reasons were many, but may be summed up briefly as follows:

1. The batteries were poorly designed.

2. No attention was paid to the mechanical features, the chief idea being to get the greatest capacity for the lightest weight.

3. The batteries were much over-rated, their full capacity being given as their normal working capacity.

In addition to this the storage battery business generally was in an unsatisfactory and weakly condition. Litigation was the principal cause. The fear of protracted and costly lawsuits prevented capital being invested in the business, and frightened prospective users from purchasing storage batteries.

Now, the conditions are very different. You are all familiar with the changes which have been made during the last five years in the commercial end of the business. All the disturbing elements have been removed, and the business has been put on a proper and substantial basis. These results are best seen from the diagram, Fig. 1. The figures for 1898 have not been tabulated, but they will show that the use of storage batteries is progressing more rapidly than ever:

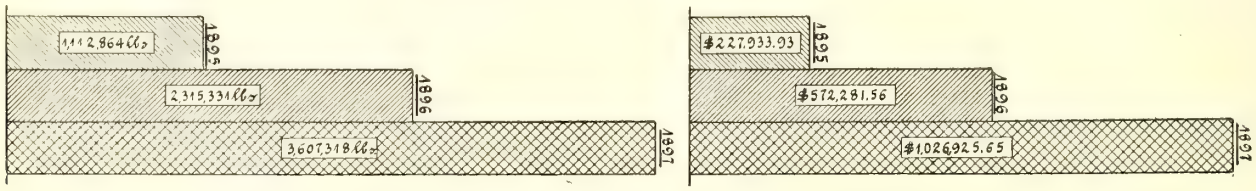

FIG. 1.—DIAGRAM OF SALES OF STORAGE BATTERIES

	Weight of plates alone.—Lbs.
1894	349,000
1895	1,112,800
1896	2,215,300
1897	3,607,300

(Or ten times the business of 1894.)

The storage battery is entirely different from any other piece of apparatus which is used for supplying electrical energy, being constructed and operated on the principle of chemical action, instead of mechanical motion. There must naturally be a vast difference between these two principles.

In the mechanically operated apparatus, or generator, the output of electrical energy is the result of the conversion of the mechanical energy applied to it while in action, and the regularity of the output is dependent on the steadiness of the mechanical energy applied, and the satisfactory running of the generator and motive power. The operation is purely mechanical, and is subject to the interruptions to which all moving machinery is liable. Again, such apparatus, if overloaded to an excessive degree, give visible signs of distress, and, if the overloading is very great, or is continued, will probably give way in some mechanical feature.

In a storage battery hundreds of horse power can be silently stored, and thousands of horse power delivered for a short period, with no apparent action or change in the battery. The action is purely chemical, and as long as the respective elements are there to be acted upon it will surely continue.

It is this fact that makes the storage battery so reliable. Such a thing as instantaneous failure or interruption of the delivery of energy is impossible, except, of course, in the case of mechanical injury to the battery from an external cause. Any mechanically operated apparatus is liable to interruption through breakage or injury to one of its parts, but in a storage battery the chemical action will continue, and consequently the output of energy until all the material on the plates has been converted.

An overload has not the same effect on a storage battery as on a mechanically operated generator. For a short period an overload, even of great extent, does not injure a storage battery. It causes the chemical action to take place more rapidly, or, to be more exact, causes more material to be subjected to the chemical action, and this, if not continued too long, or repeated too often, does not affect a good storage battery. Moreover, if the overload is continued too long, it does not mean the sudden failure and collapse of the battery and complete interruption of the output, but is shown by the premature depreciation of the plates in the battery. It may not be noticed for months or even years.

One of the most valuable features of a storage battery is that it will safely take care of any sudden and momentary overload in the system, such as grounds or short circuits, and if operating in parallel with generators or rotary converters, will relieve them of such overloads and consequent strain. I have frequently seen batteries burn out grounds on an underground system, discharging for a short time at an enormous rate. And in the case of batteries operating on railway loads, it is a common thing to see an occasional momentary discharge at a rate equal to twice the hour rate of the battery. The modern storage battery is designed to stand such occasional extreme discharges, and do so without injury.

It may be well to consider, before going further into our subject, the question of the rates of charge and discharge of storage batteries, and their capacity at different rates. Of course, this will vary somewhat with different types of battery, but not to a great extent. The more rapidly you discharge a battery the smaller is its available capacity. For example, the curve, Fig. 2, illustrates the available capacity of a storage battery when discharging at any rate between the ten-hour and one-hour rates. That is to say, when the battery is completely discharged in ten hours and in one hour. It is only within the last few years that a one-hour discharge rate has been possible with a storage battery, and it is very largely due to the fact that storage batteries can be discharged at such rapid rates that their use has been growing so rapidly.

In large engineering problems the storage battery is used chiefly to supply large amounts of electrical energy for short periods, and by increasing the allowable rate of discharge the size of the battery required is consequently reduced. In connection with this question of the reduced capacity of storage batteries at rapid rates of discharge, there is frequently a mistaken idea that if the capacity of a battery is thus reduced, the efficiency is correspondingly impaired. This is not so at all. It is only the available capacity of the battery which is reduced by polarization, or, in other words, the chemical action when taking place at such rapid rates can only reach the active material which is on the surface of the plates and immediately exposed to to the electrolyte. Hence, in reality, the actual capacity of the battery is not reduced, only the available capacity, and when the battery is recharged, only the active material that is acted upon has to be converted and not the entire amount of active material. There is a slightly greater loss in efficiency when discharging at a rapid rate due to the internal resistance of the battery, this being the C^2R loss.

Storage batteries are not free from trouble, any more than any other apparatus, but, under favorable conditions, the comparison is much in favor of the storage battery. No piece of apparatus yet made is perfect, and its usefulness and consequent general adoption may be said to be proportional to the predominance of its useful features, over its weaknesses or troubles. The rapid growth in the use of the storage battery during the last few years is the best proof possible that its troubles are very small compared to its advantages.

As is the case with all machinery and apparatus which have to be operated continually for any length of time, the results obtained depend not entirely on the design and construction, but on the care and judgment with which it is operated. This fact is particularly noticeable to any one who is constantly brought into contact with different plants and installations, as I am, and under different management, or sometimes mismanagement, in all parts of the country, and this subject alone would afford a very interesting and profitable topic for discussion and consideration.

In the early days the storage battery manufacturers, in order to maintain a bare existence, had to jump at every opening for the use of a storage battery, whether the conditions warranted it or not, and, in order to do business, accepted contracts drawn entirely from the purchaser's point of view, without regard to the capabili-

* Abstract of paper read before the New York Electrical Society Jan. 12, 1899.

ties of the storage battery, and guaranteed results which, to say the least, were extremely difficult to realize. What the results of all this was you know very well.

Now, things are entirely different. The business is on a commercial basis, and it is not a question of getting an order at any price, but securing business which will prove satisfactory and permanent. Now, storage battery manufacturers will insist on proper conditions for the operation of their batteries, or refuse to put them in. This is as it should be, and I think I am perfectly safe in saying that during the last four or five years there has not been a storage battery installed in this country, except under conditions which justified its use. Of course some experimental applications have been made which may or may not prove satisfactory, but this does not come under the head of the general application of the storage battery.

It should be distinctly understood that all conditions of electrical distribution are not suitable for the use of storage batteries, and that it is more to the interest of the manufacturer than the purchaser to confine himself only to those situations which are suitable, for every failure which is recorded is heard of one hundred times to every success.

Now, that by this method of doing business, confidence in storage batteries is being regained, and proper relations have been established between manufacturers and users, the growth of the use of storage batteries will be still more rapid, for it is now realized that when storage batteries are installed and operated under proper conditions the result will invariably be satisfactory.

The trend of electrical engineering is to-day toward the concentration of generating machinery, the highest possible economy in operation, and the utilization of motive power and generating ma-

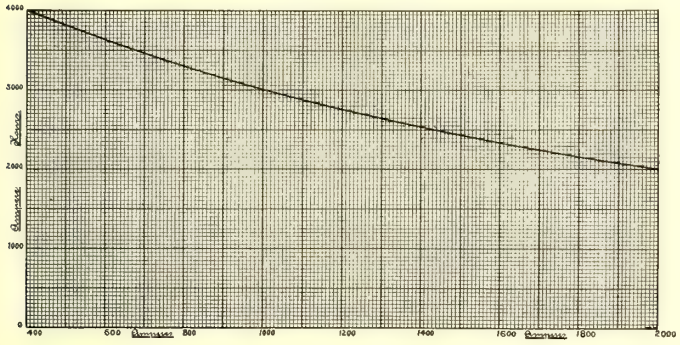

FIG. 2.—CURVE SHOWING CAPACITY OF CELL WITH DIFFERENT RATES OF DISCHARGE

chinery to the fullest extent, so that the investment may produce the greatest return. These conditions make the storage battery indispensable, for without its aid it is impossible to maintain a constant load on the power house.

Every application of electricity has its time of maximum output or "peak," and no matter how many different applications are supplied from the same system, their peaks will not fit in so as to even matters up, but, on the contrary, it is found that in many cases the peaks occur at about the same time. This is particularly noticeable with a railroad and lighting load. Again, concentration of generating machinery means a much larger area for distribution, and the necessity of sub-stations, in order to keep down the investment in conductors, and experience shows that in the majority of cases storage batteries are cheaper than the copper alone, which would otherwise be necessary, leaving out the advantages at the power house. This means that the storage battery will now play a most important part in all electrical problems, and be of sufficient importance and value to warrant the conditions being made suitable for its use instead of, as in early days, being dumped in at any time to fill up a gap and smooth over any difficulties which cropped up.

It used to be customary to refer to European practice, to show what could be done with storage batteries, and even now, I believe that some people think that European batteries and methods are superior to ours in this country. In connection with this idea there is one thing which I particularly wish to emphasize, and that is, the difference between American and European conditions.

In Europe storage batteries are not subjected to the severe work they have to stand here. They are looked upon more as a reserve, and are not expected to discharge at their maximum rate every day, and, perhaps, twice on some days.

As an example of this, I will tell you what one of the Tudor Company experts from Germany said when he was over here last spring. He was attending the National Electric Light Convention at Chicago, and one of the features of that convention was the large storage battery plant, which the Chicago Edison Company had installed. During one afternoon, while the convention was being held, a very heavy thunderstorm came on, and the battery was called upon suddenly for its maximum rate of discharge, and the full rated capacity was taken out. The maximum rating of this battery was a complete discharge in one hour. Our German friend thought that was doing pretty well, but, when I told him that this storage battery was installed under contract, which allowed the battery to be discharged at this rate every day during the winter, he was horrified, and said:

"You must not let them work the battery in that way; tell them they must hold it as reserve." We told him that if we did that we should not be able to do any business, and that we simply had to meet these conditions, and could do so without any difficulty. This instance will show why batteries are maintained at a lower figure in Europe than here, and why it has been customary to refer to the behavior of the battery in Europe. It is a fact that we have now in this country many storage battery installations which surpass any thing in Europe, both in size and method of operation.

The methods of applying storage batteries in connection with electrical engineering work are so numerous that it would be impossible to deal with them all this evening, so I have selected a few for consideration as showing clearly the great flexibility of the storage battery as an adjunct to any scheme contemplating the generation and transmission of electrical energy.

In a lighting and power station the maximum load occurs for only a very short period during the year. In one station I know of 50 per cent of the investment in generating plant and underground conductors is only used for 154 hours during the year. This statement may seem astonishing, but will be found to apply to many such stations. Where these conditions exist it will readily be seen how great are the advantages of storage batteries as auxiliaries. Their cost per kilowatt of output for short periods, such as these peaks, is less than the generating machinery which would have to be provided if they were not used, in addition to which there are other ways in which they prove advantageous in the operation of the plant.

The application of storage batteries to such stations, such as this, can be made in two ways, viz., at the main power house or in sub-stations. Each method has its own advantages, and should be determined in each case by the conditions which exist.

When batteries are placed in sub-stations they will relieve the generating plants of the maximum load as just described, and also effect a large saving in the underground system of conductors, as, at the time of maximum load, the conductors between the main generating station and the sub-stations are relieved of that portion of the load which is carried by the batteries, and distributed from the sub-stations.

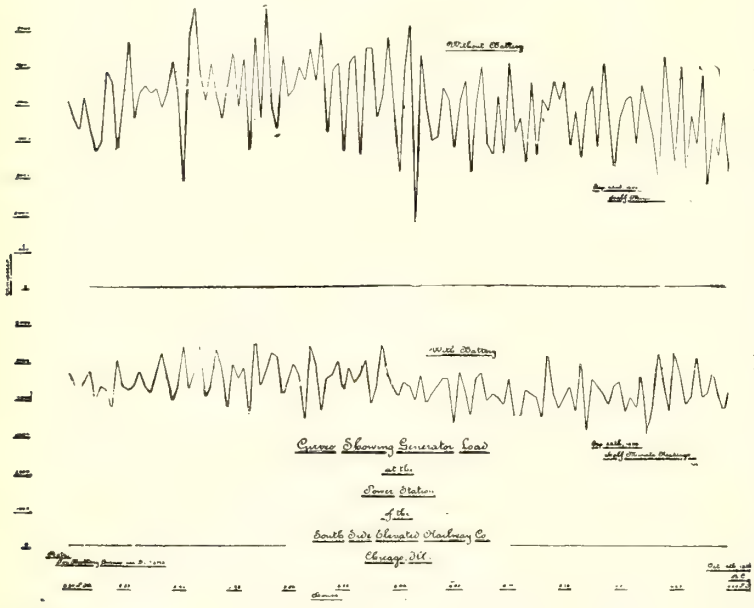
The use of large water power as a motive power for generating stations from which electrical energy is transmitted and distributed over extended areas is growing. Take, for example, the Niagara and other plants. In connection with such installations storage batteries play a very important part. The power from such a plant is largely sold for manufacturing purposes and is charged for at so much per horsepower per annum, the power being available twenty-four hours per day, while mills and factories using this power do not usually run for more than ten hours per day. Therefore, a man who requires a maximum of 100 h.p. for ten hours a day, or 1000 h.p. hours, really has to pay for 2400 h.p. hours, while he uses only 1000, and probably less; for the average, rarely, if ever, exceeds 70 per cent in the maximum.

With a strong battery capable of supplying 50 h.p. for ten hours, or 500 h.p. hours, he need only pay for one-half the amount of 50 h.p. for 24 hours, as the battery will furnish the remainder, and can be charged during the fourteen hours he is not using the power. In addition to this, the battery will take care of any fluctuation above the average and enable the man to buy the average amount of power he requires, instead of the maximum.

Such an installation has been made by the Buffalo Street Railway Company. Before describing this installation, I would like to mention the different methods of installing storage batteries in connection with railway plants. These may be divided into two classes.

First—Where the battery is installed at the power house to take care of the peak of the load, and the fluctuation of the generators; and,

Second—Where the battery is installed at the end of a long feeder to keep up the pressure at that point, and to obviate the necessity of sending the maximum amount of current over the long feeders from the power house.



We will consider an installation of each kind and their respective methods of operation.

The Buffalo Street Railway Company's plant* is of the first class, and is especially interesting inasmuch as it is operated in connection with the Niagara Falls power. They operate practically all the cars within the city limits, and have a steam plant capable of

* See STREET RAILWAY JOURNAL, July, 1898.

delivering 7,000 electrical h.p., in addition to which they take 2000 h.p. from the Niagara Falls power, this current being transmitted in the form of high tension alternating current from the Niagara Falls to the power house, and being then transformed by rotary converters to the ordinary 550-volt direct current.

The storage battery is installed at the main power house and is connected directly in parallel with the steam plant and rotary converters. When a storage battery is installed at the power house, and is connected directly in parallel with the generators on the

FIGS. 3 AND 4.—CURVES SHOWING REGULATING EFFECT OF BATTERIES ON SOUTH SIDE ELEVATED RAILWAY

bus bars some means have to be provided for regulating the voltage of the battery to suit the generators. As you know, railroad generators are over compounded, the voltage rising as the load increases, while with the storage battery the reverse is the case, the voltage decreasing as the discharge increases. In order to make the battery work properly in parallel with generators of this type and take the fluctuation of the load, keeping the generators constantly loaded, means of compounding the battery have to be adopted. This is done by using a compound motor booster in series with the battery, which is so designed as to increase its voltage in proportion to the increase of the load, thereby enabling it to take its proper share and keep the load on the generators constant.

The battery discharges during the morning and evening peak, and is charged between times, and also at night from the Niagara Falls power. By the aid of the battery they are enabled to make very much more use of the Niagara Falls power. Before they installed the battery they were only able to shut down their steam plant from 11:30 P. M. until 5 A. M., during which time the rotary converters carried the entire load, which averaged about 600 h.p., while they were paying for 2000 h.p. With the aid of the battery they are enabled to shut down their steam plant from 7 P. M. to 7 A. M., and about eighteen hours on Sunday. In addition to this they are enabled to utilize very much more of the Niagara power.

An illustration of the second method of using storage batteries for railroad work is seen in the case of the battery in the installation of the South Side Elevated Company of Chicago. This company operates an elevated railroad about 9 miles long, all their trains being equipped with the Sprague multiple unit system. The power house is located approximately at the centre, and the two storage batteries near each end of the line, and are connected directly across the system without a booster. The charge and discharge of these batteries is controlled by the drop of the feeders from the power house to the batteries, this drop varying according to the load on the system from 10 to 80 volts. When the load of the system is light the drop in the feeders is small, and there is voltage enough to charge the battery. When the load becomes heavy the drop on the feeders is increased, this consequently causes the batteries to discharge into the line. The method of operating is entirely automatic, the batteries discharging at times of heavy loads, and charging at times of light load, thereby keeping the load on the generating station practically constant. The two battery rooms, each containing 248 cells, have a capacity of 1000 h.p. when discharging at the hour rate. The curves, Figs. 3 and 4, show the result which the batteries have had on their generating plant. The first curve, Fig. 3, shows the load on the generators when they were operating the entire system without batteries. The second, Fig. 4, shows the load on the generators under the same conditions with the batteries in use.

It will be noticed from these curves that when the power house was operating without the battery during the peak of the load the maximum load was 7500 amps., with sudden fluctuations of 5300 amps., while with the batteries in operation the maximum load at the power house under exactly the same conditions was 5700 amps., and the fluctuations only 2000 amps. Thus, the batteries have increased the capacity of the power house by about 2000 amps., and steadied the load on the generators to the extent of nearly 3000 amps. Those acquainted with the operation of street railway plants will appreciate such results.

Each battery is connected to the power house by two special feeders in addition to the general system of conductors, so that the proportion of charge and discharge can be regulated according to the conditions of the load.

If it is found that a battery is being discharged more than it is being charged, an extra feeder is connected between it and the power house, so that it will be relieved of a portion of the load. By this means a very complete control can be maintained of the battery from the power house, and the most efficient method of operation secured.

A battery installed at the end of a line in this way, not only increases the capacity of the power house and saves the investment in copper by making it only necessary to transmit over the feeders the average amount of current required, instead of the maximum, but at the same time it maintains the proper voltage at the end of the line, thereby enabling the motors to run at the point of highest efficiency. Of course the line must be long enough to justify the use of a storage battery and to supply sufficient drop in voltage over the feeders to make the battery operate automatically as the load varies.

A variation in voltage at the end of the line, between conditions of maximum load and minimum load of 10 per cent, is ample to make the battery self regulating, and take care of the fluctuating load without a booster. The following figures taken from a storage battery installation of this description installed some two years ago, will show the advantage from a commercial point of view.

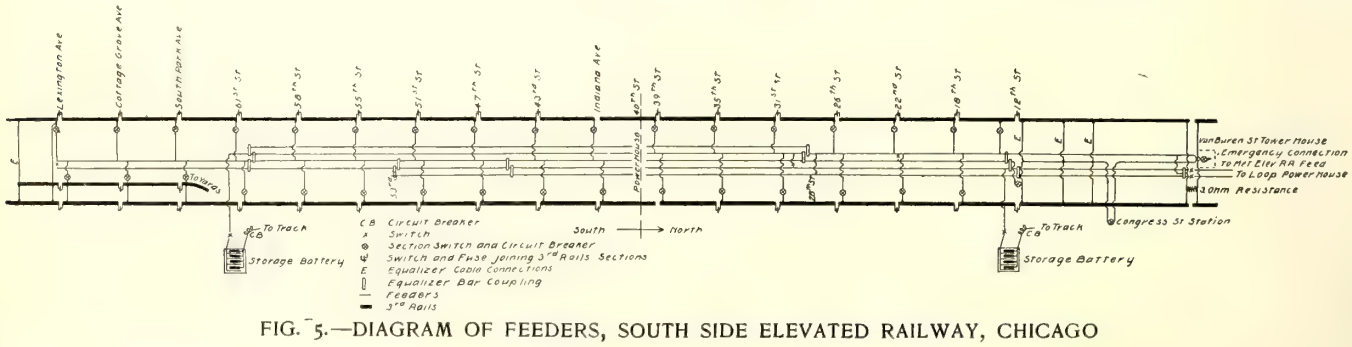


FIG. 5.—DIAGRAM OF FEEDERS, SOUTH SIDE ELEVATED RAILWAY, CHICAGO

The conditions were as follows: The length of this line at the end of which the battery was installed, was 7 miles from the main power house, running into the suburbs of a large city. The increase of traffic on this line warranted its extension 4 miles further, making a total of 11 miles from the power house. When the extension was made, it was found that the feeders were quite inadequate to carry the increase of load, and it was unnecessary to provide additional power at the end of the line, either by laying additional feeders, installing a small power house at that point, or putting in a storage battery sub-station. Each method was carefully considered, and the following figures show the result. If additional feeders were laid of sufficient sectional area to provide the proper working voltage at the end of the line the cost would have been $273,000, figuring on the basis of $1.00 per foot,

laid for 1,000,000 c.m. feeders. This was, of course, prohibitive. The cost of a small power house of sufficient capacity to take care of the load in that section of 750 kw. would have been $85,000. The cost of a battery sub-station complete, including real estate, was $33,000, or a saving of $52,000 over that of the power plant.

The cost of operation has proved exceedingly satisfactory, showing a saving of some $1,350 per month, or $16,000 per annum over the cost of operating a power house of such a size. The cost of operation includes all attendance, taxes and depreciation and interest.

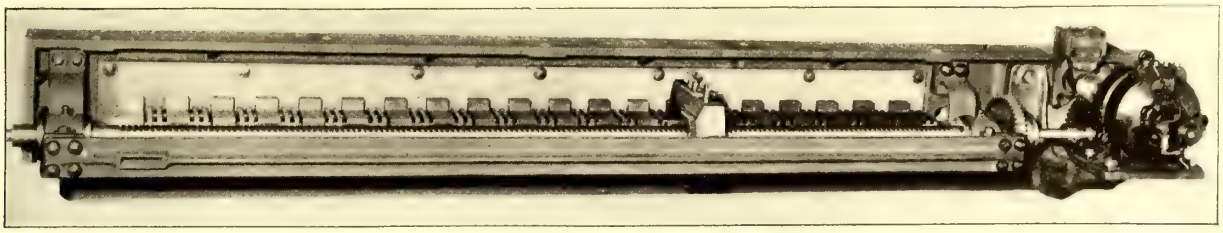

FIG. 6.—SWITCHING DEVICE FOR END CELLS

One of the most interesting and important storage battery installations recently made is that in connection with the underground trolley system of the Metropolitan Street Railway Company of this city. This company's system covers a large area, and it has utilized storage batteries in sub-stations. Two are now in operation, one at the foot of West Twenty-third Street and the other at Thirty-second Street and Fourth Avenue.

I will briefly outline this plant and method of operation. The battery consists of 540 cells, each containing fifty-one plates, 15 ins. square. The dimensions of the cells are 4 ft. x 21 ins. x 24 ins. The battery is divided into two sections, 270 cells in each, which are operated in parallel. This is done to keep the sizes of the cells within practical limits and to enable them to be more easily inspected and cared for. A cell 8 ft. in length, which would be the size if but one battery were used, is too large to be satisfactory. The capacity of the complete battery is 8000 amp. hours, with a one-hour rate of 4000 amps.

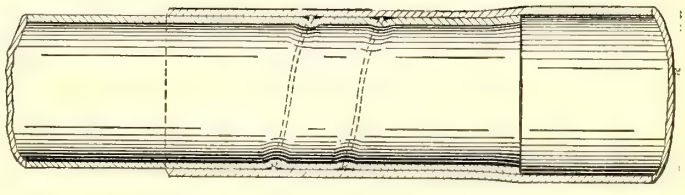
The function of this battery is to take care of a portion of the morning and evening peaks, and to take up the fluctuations of load at all times. The method of operation is as follows: Sufficient cells are provided so that the voltage of the battery just balances the average voltage of the system; consequently, when the battery is connected to it, it acts as an equalizer and does not charge or discharge except as the fluctuations occur. When the battery discharges on a peak and is being charged during the hours of light load, a booster is connected in series with it to regulate the amount of a charge and discharge. The output of the booster and, consequently, the charge and discharge of the battery, is controlled by varying the strength and polarity of the shunt field. This is done by a special form of switch which makes the operation very simple.

The daily work of the battery is about as follows: From 7 to 9 A. M. it discharges on the peak. From 9 to 12 it floats on the system as an equalizer. From 12 to 3 or 4 P. M. it is charging. From 4 P. M. to 8 P. M. it discharges on the peak. From 8 to 12 midnight it is floating on the system, and after midnight the battery is given its principal charge, this being continued until the battery is full.

An interesting application of this sort has recently been made on a small railroad plant in Montpelier, Vt.* This plant was, I believe, the first railway plant in this country operated exclusively from rotary converters with a storage battery auxiliary. The line operated is about 9 miles long, and the sub-station is located about 3 miles from one end. The power is furnished from a power house on the Winooski River, the current being generated by three-phase alternators at 2200 volts. This current is carried to step-up transformers and is raised to 6300 volts. At this pressure it is carried to the sub-station, a distance of 8 miles. In the sub-station step-down transformers reduce this to 480 volts, at which pressure it is fed into the rotary converter. The capacity of this converter is 160 kw., and is specially wound for running directly in parallel with a storage battery, its characteristic curve being similar to a shunt-wound generator. That is to say, as the load increases, its voltage would fall. By this means the battery will take care of all fluctuations, maintaining a fairly constant load on the rotary. The battery consists of 248 cells, each containing eleven plates 10 ins. square. The one-hour rate of this battery is 200 amps. The maximum load on the line is 300 amps. Of this the rotary carries 125 and the battery 175. The greatest amount of load on the line is nearly 300 amps. Such an installation shows clearly the advantages of battery regulations on a fluctuating load. The size of the rotary is reduced practically one-half and the load on it kept almost constant.

Most of the plants mentioned have been those of a large size, supplying a large amount of energy. It must not be imagined that storage batteries are applicable only to these large stations. The variation of load on the rotary is 50 amps., while the variation of results obtained from their use are just as satisfactory in the case of smaller stations, but I have referred to the larger ones as being of more interest.

* See STREET RAILWAY JOURNAL, September, 1898.



Increase in the Use of Aluminum for Electrical Conductors

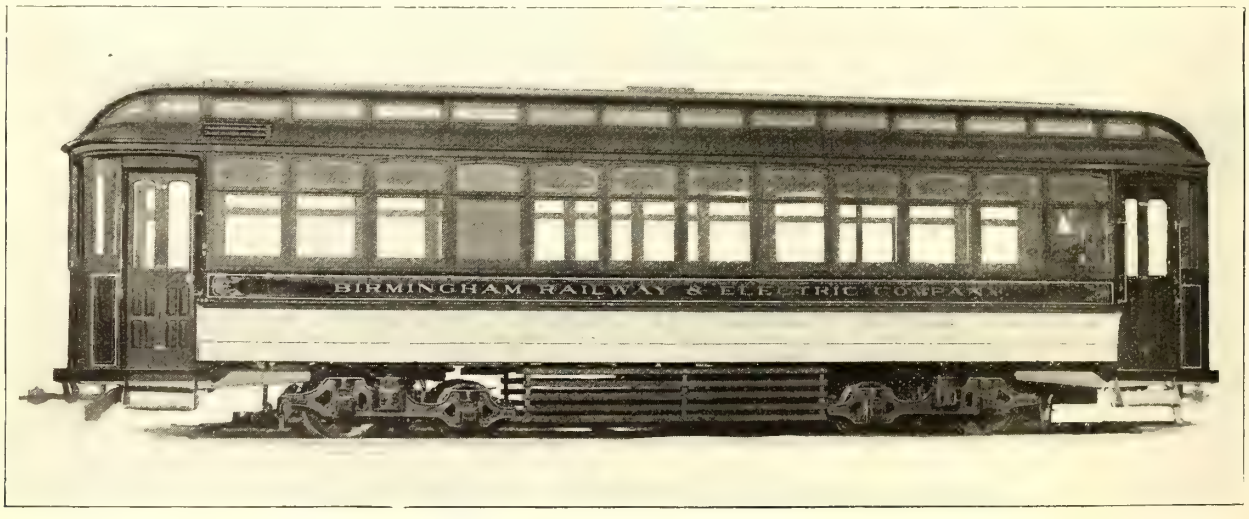
The Pittsburgh Reduction Company, manufacturers of aluminum, report an extended increase in the use of this material for electrical purposes. The company itself has had 10,000 h.p. of current transmitted by aluminum conductors for the last two years, and the Niagara Falls Hydraulic Power & Electric Company has used a considerable amount of this material for electrical conductors. Among the longer lines which have employed this material is one at Snoqualmie Falls for the transmission of power from the Falls to Seattle and Tacoma, where more than 80 miles of wire is in use. The Standard Electric Company, of California, the Pennsylvania Railroad Company, the Bell Telephone Company, and others, have also employed the material to a considerable extent on their conductor systems for telegraph and telephone conductors.

The Pittsburgh Reduction Company is installing two 14-in. and four 10-in. mills with continuous drawing benches for the manufacture of aluminum wire for use as electrical conductors, and expects to have as large facilities as any mill in the country for this work.

Orders for Street Railway Supplies

Elmer P. Morris, of New York, manufacturers' agent for some of the largest and most representative supply houses in America, reports an unusually large number of orders during the past month for the specialties he handles. This is particularly true of assembled commutators, made from drop-forged copper and tubular-iron poles and brackets. A cut of the poles he carries in stock is shown herewith. These are made in two or three sections as desired, and at each joint are bound with wire, which is swaged and keyed into place in such a way as to give enormous strength to the pole. These are guaranteed to stand a hydraulic pressure from the inside of 200 lbs.

SECTION OF POLE



Mr. Morris has recently opened several new branch offices for the convenience of street railway companies at a distance from New York. One of these is in the Betz Building, Philadelphia, and will be in charge of George E. Pratt; another is at Niagara Falls, N. Y., and will be in charge of C. J. Harrington.

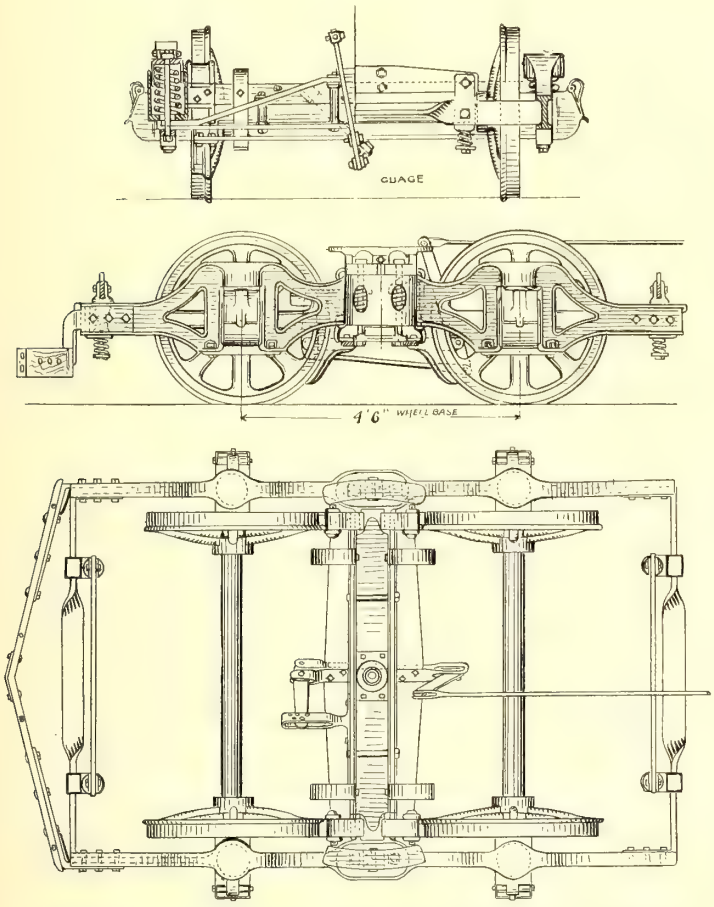
New Cars Built in St. Louis

The accompanying illustrations show two new cars recently built by the St. Louis Car Company for the Bloomington (Ill.) & Normal Railway Company and the Birmingham (Ala.) Railway & Electric Company. These furnish a good illustration not only of the new era in American street railway car building which has set in with the development of long suburban and interurban lines, and which has had no little effect upon street railroading in cities proper, but also of the good work of the St. Louis Car Company itself, which, with its new factory, now practically completed, will be one of the greatest street railway car manufacturing establishments in the world. The lines of these cars are graceful, and it is evident that careful thought and care have been given to every detail of their construction as affecting the carriage of passengers. The twelve windows of the Bloomington and Birmingham cars guarantee lightness in winter and lightness and airiness combined in summer. The square sides give roominess of car inside, and the patent vestibules of the St. Louis Car Company protect the motormen, conductors and passengers. In fact, the Bloomington car particularly, closely resembles in general appearance the passenger coaches of the Limited Express between New York and Chicago.

ELECTRIC CAR FOR BLOOMINGTON & NORMAL RAILWAY

ELECTRIC CAR FOR BIRMINGHAM RAILWAY & ELECTRIC COMPANY

These cars are mounted on the new No. 18 double track of the St. Louis Car Company, illustrated on page 115. Orders for large numbers of these trucks have already been taken by the St. Louis Car Company, in spite of the fact that they have been in the market but a short time.



The Walker Company has received an order for the electrical equipment of eighteen cars in Krementschoug, Russia, and thirty-six cars for the Omnibus and Tramway Company, of Rome, Italy.

Electric Locomotives on the Orleans Railway Terminal in Paris

The plans for operating the terminal of the Orleans Railroad in Paris by electric locomotives, some particulars of which were given in the STREET RAILWAY JOURNAL for June last, have since been determined upon. The line, whose service is very similar in character to that of the Baltimore & Ohio Railroad in the Belt Line tunnel, in Baltimore, has a length of 3700 m., of which 3100 m. are underground, and electric locomotives are to be employed to avoid the gases of combustion in the tunnel. The substitution of electric locomotives for steam locomotives will take place at the Austerlitz Depot in the outskirts of the city, while a stop is made to discharge passengers, and from that point to the main station at the Quai d'Orsai trains will be drawn by electric power. The power station will be near the Tolbiac Bridge, and will contain two units of 1000 kw., each producing three-phase current at 5500 volts and 25 cycles. This current will be transmitted to three sub-stations, one in the power station itself, one at the Austerlitz Depot, and one at the Quai d'Orsai Depot, where it will be transformed to a 500-volt continuous current for lighting and traction. In the two latter sub-stations will also be located a battery of accumulators in parallel with the rotary converters to regulate the voltage and insure lighting at a period of the night when the power station is not in operation. Each power station will also contain static transformers for reducing the current from 5500 volts to 340 volts and two 250-kw. rotary converters operating at 500 r.p.m. Each of the batteries will have a capacity of 1100-amp. hours.

The electric locomotives will be operated by a continuous 500-

volt current by means of a third rail carried on blocks of paraffined wood resting on the ties. There will be eight locomotives supplied by the General Electric Company, similar in general appearance to the Baltimore locomotives. Each locomotive will be of 500-kw. capacity, will weigh, empty, 40 tons, and loaded, from 45 to 46 tons, the weight necessary to draw a train of 250 tons, including the locomotives, from the Quai d'Orsai

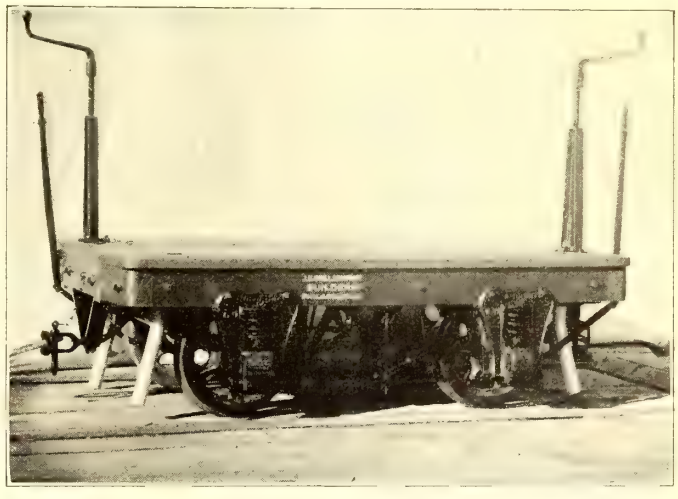
PLAN, END AND SIDE ELEVATIONS OF THE NO. 18 TRUCK

station to the Austerlitz station in seven minutes without intermediate stops. It is estimated that the traction consumption of power will be about 1,420,000-kw. hours per year for the normal number of 150 trains per day, empty or loaded. It is estimated that the trip from Quai d'Orsai to Quai Austerlitz in seven minutes without intermediate stops will consume about 27 watt-hours per ton. The average train of 200 tons, including engine, will absorb, it is thought, 600 kw. at starting and 250 kw. at full speed. The expense of building the power station, sub-station, supplying the rolling stock and building the transmission line is estimated at $610,600, and it is expected that the entire road will be in operation by January, 1900.

Calendars for 1899

Numerous calendars for the year are still being received, and many of these bear evidence of most careful designing, and in a number of cases very large sums of money must have been spent in their preparation. Among those received since Jan. 1 is one from the Joseph Dixon Crucible Company, of Jersey City, bearing an interesting reproduction of a young college girl in gown and mortarboard, evidently on the day of her graduation; another one, issued by the Ashton Valve Company, of Boston, Mass., shows two little girls at play; a very elaborate calendar, by Mayer & Englund, of Philadelphia, Pa., shows a large lithographic reproduction of a young woman's head in colors; the Peckham Truck Company, of New York City, is sending out its large wall calendar, which has become well known to the street railway field; R. D. Nuttall Company, of Allegheny, Pa., is sending out a calendar bearing a large cut of the Nuttall gears; the Van Dorn & Dutton Company, of Cleveland, Ohio, is sending one composed of twelve sheets, one for each month, each sheet showing and describing one of the Van Dorn specialties, including trucks, armature lifts, gears and pinions, etc. In addition to the above, two other very handsome calendars have been received, one from the J. G. Brill Company, and the other from the Sprague Electric Company. The one from the Brill Company is unusually elaborate, and consists of six large sheets, upon each of which is printed a reproduction of a famous painting, the six reproductions being "The Three Fates," "Spring," "Good Morning," "Love Wins," "Butterflies," and "Cinderella." Each sheet contains also the calendar for two months. The Sprague calendar is one of the handsomest and most thoroughly practical ones received. The upper part is a copy of a celebrated painting, while the calendar proper, printed from a good size type, forms the lower half. Both parts are mounted in a mat and nicely framed. D. E. Goe, manager of the advertising department of the Sprague Company, has a great reputation for doing this kind of work, and in doing it just right.

Convention of Manufacturers



The fourth annual convention of the National Association of Manufacturers of the United States was held at Cincinnati, Ohio, Jan. 24, 25 and 26, 1899. The meeting was well attended, and subjects of interest to American manufacturers were discussed. The following officers for the next year were elected: President, Theodore C. Search, Philadelphia; secretary, F. P. Wilson, Cincinnati, Ohio; treasurer, Charles A. Schieren, New York. The next meeting will be held at Boston, Mass.

Special Number

The twentieth annual number of "The Tradesman" of Chattanooga, Tenn., is a very elaborate number. It has been most carefully prepared, and will be found valuable as a book of reference to all interested in the growth of Southern trade.

Electric Locomotive

The accompanying illustration shows an electric locomotive recently built for the Deadwood & Delaware Smelting Company by the J. G. Brill Company. It is a powerful little affair, although it measures but 8 ft. in length and is only 5 ft. 3 ins. wide. It stands 2 ft. 3 ins. to the floor, and is furnished with a w.p. No. 5 motor, with two K 10 controllers. The wheel base is 4 ft. and the gage of the track 36 ins. Its small size and compactness made it possible to use a light pedestal gear arranged to take the motors. Four Brill sand boxes are placed within the frame to give an equal and complete distribution of sand when it is necessary. The convenience of a machine of this kind is hardly to be estimated by those who have had no experience with them. One man can handle almost all the loads that may be necessary about an establishment.

ELECTRIC LOCOMOTIVE

In this case the machine is a flat car as well as a locomotive. It is intended for use within a mine and on the surface as well. A third rail transmission of power is to be employed, and the General Electric Company put on the necessary electrical equipment. It is interesting to note that an electric locomotive, as adapted to every-day commercial uses, is coming to be more and more employed. Electricity is available in a large percentage of all manufacturing establishments and railway tracks are equally commended. A small expense for overhead wires or for third rail conductors makes a machine of this kind possible, and its convenience is much greater than a pair of horses, while the economy is in favor of the electric machine, which, when not in use, is not "eating his head off."

Water-Softening Plants

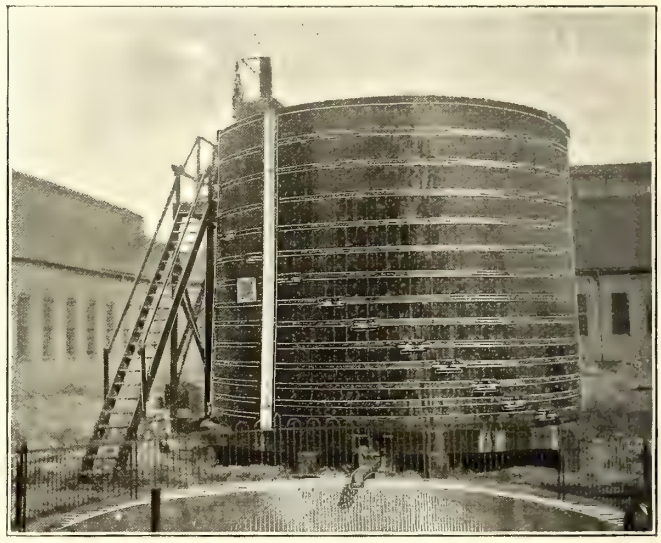
BY N. O. GOLDSMITH

The advantages of water softening are not generally understood or appreciated in this country. The process was discovered nearly sixty years ago by Dr. Clark, of Aberdeen, Scotland, and since that time it has been extensively adopted in England, not only for softening the water supply of whole towns and cities, but also for various requirements of the mechanical arts. Hundreds of water-softening plants are in successful daily use in Great Britain, France, Belgium and Germany. The mechanical features of these may differ according to the ideas of the designer, but all make use of the same chemical process. These plants are softening water for steam boilers, railways, woolen and cotton mills, paper mills, iron works, dye works, tanneries, etc. From this it will be seen that the process is not a new and untried one, still in the experimental stage, but one which is as well established, and whose advantages are as well recognized, as are those of the exhaust steam heater in this country. As an apparatus for furnishing suitable and desirable feed water for boilers, it is also the cheapest purifier of any merit in the market. The common mineral impurities soluble in water are silica, iron, carbonate of lime and magnesia, sulphate of lime and magnesia, and chloride of lime and magnesia, also the chlorides and sulphates of soda or potash. The lime and magnesia and iron salts are known as the scale-forming impurities, and are the ones which are removed by water softening. At the same time that these are removed, the mud or silt which the water may contain is also removed, and the organic matter reduced. The sodium and potassium salts do not form scale and are not removed by this process, nor is it possible to do so by any process of purifying water, with or without the aid of heat. The only means of removing sodium or potassium salts from water is by distillation, and this is the process which takes place in the boilers. The lime and magnesia salts are held in solution by means of the acids with which they are united. Water softening, therefore, is a process of removing from the lime and magnesia these acids which hold them in solution. The expense due to softening water is extremly low, first, because the carbonates are generally more abundant in waters than the sulphates or chlorides; second, because the Clark process will remove a higher percentage of carbonates than any other method, which would be practical and economical enough to use for industrial purposes.

The following table is copied from the report of W. J. Dibdin, chemist for the London County Council, who conducted a series of experiments on water of the New River Company:

Date, 1895.	Before softening.		After softening.		Percentage of reduction.	
	Hardness.	Bacteria.	Hardness.	Bacteria.	Hardness.	Bacteria.
December 16..	17.4	96	5.4	12	68.4	87.5
" 18..	17.4	110	5.0	6	71.3	94.5
" 20..	17.4	60	8.5	16	51.2	73.4

Hardness is expressed in degrees, Clark, and bacteria given in colonies per cubic centimeters.



The most approved method for softening water is known as the intermittent settling tank plan, in distinction from the continuous method of purification, in which the water is always moving and is purified in transit. Where the quantity of water required is comparatively small, much more satisfactory results are obtained by using the intermittent settling tank plan than would be possible with the continuous system.

The apparatus is extremely simple, and consists of two or more open tanks, or one tank and a storage reservoir. These tanks may be constructed of wood or iron, as preferred. They are generally made cylindrical, and usually located out of doors, convenient to the boiler room. This has the advantage of not crowding up the boiler room, while there is no danger of the water in the tanks freezing while the plant is in daily use. The size of the tanks depends upon the quantity of water required per day, and the number of times it is convenient to fill them. Each tank is placed upon a heavy platform carried upon foundation piers, and is provided with a mechanical stirring device to be used in mixing water with chemicals. This stirring device consists of a paddle revolved by the simple gearing turned by hand, or preferably by light power. This paddle stirs up from the bottom of the tank the lime sludge of previous precipitation; this floats in the water, hastens the chemical reaction, and causes the new finely-divided precipitate to gather into large flocculent or wooly flakes, which settle quickly as soon as the water stops moving. The simplicity of this means for stirring and agitating the water is self-evident; it does not have to be cleaned to keep it in working condition; it requires from ½ h.p. to 3 h.p. to operate it, so that the amount of steam is extremely small.

The softened water after settling is taken from the tanks by means of a hinged floating outlet pipe, which rises and falls with the level of the water; by this means the clearest water is always drawn from top of the tank.

Inlet connections through which to fill the tank, and wash pipe connections through which to wash lime sludge from tanks, are placed in the bottom. The washing of the settling tanks need be done only when lime sludge becomes deep enough to interfere with stirring; ordinarily, once a week or a fortnight is sufficient. All that is required is to open wash valve, start the stirring device, and mix up the lime sludge with the water, which is always left in the bottom of the tank, for it is soft enough to run out through the wash pipe. The time and labor of cleaning is but a small percentage of that required for exhaust or live steam heaters, and it is not necessary to do the work on top of the boilers in a hot, stifling atmosphere.

A sheet iron chemical tank is placed on top of the settling tanks; in this are placed the reagents used for softening; they are mixed with water and washed into the tanks while filling. By reason of

WATER SOFTENING PLANT AT COLUMBUS

the currents of water caused by the water rushing into the tank, the chemicals are partially mixed with the hard water; this mixture is completed by the revolving paddles of the stirring device, which are started as soon as the filling of the tank begins, and continues to revolve until the tank is full. This method is very efficient, involves no expensive apparatus which requires constant cleaning and repairs, and is very economical in steam. Tank indicators are generally placed on tanks to show level of water, and operating platform is arranged alongside of tanks from which the man in charge mixes reagents and tests the water. The testing of the water is made necessary because of the exact treatment, and the variation which takes place in all waters. The test is extremely simple, and any man of ordinary intelligence can understand and use it.

The advantages of this apparatus are as follows:

First: There are no automatic chemical feeds which continually vary, and thus furnish either an excess or an insufficiency of the chemical solution.

Second: In moderate sized plants the apparatus can be operated by the engineer, or his assistant, without interfering with the regular work.

Third: The constant quantity of raw water collected in the tanks is treated with practically an uniform amount of chemical reagents, therefore an uniform character of softened water is furnished. The simplicity of this plant makes it possible for the unskilled workman to obtain as good results as an expert chemist.

Fourth: The mechanical stirring which results in agitating the raw water with the chemical reagents insures an intimate mixture, and very materially hastens and completes the chemical reaction.

Fifth: The sludge of previous purification which has settled to the bottom of the tanks is mixed with the water by the action of the stirring device; this insoluble matter moving in the water gathers up the new finely-divided precipitate and hastens the clarification of the water.

Sixth: The sludge collected in the settling tanks relieves the filter beds, so that the filter can be run five or six times as long,

without cleaning, as would be the case if all the sludge was intercepted by the filters.

Seventh: The settling tanks do not require washing oftener than once a week therefore, the amount of water required for cleaning is a very small percentage of the total amount purified.

Eighth: The length of time which the water stands is necessary in order to get complete chemical reaction. No chemical reaction is instantaneous, therefore the element of time is necessary.

Ninth: The perfect quiet of the water gives an opportunity for most complete settling, rendering unfiltered water clearer than that from any other apparatus not using filters.

Tenth: The operations of this apparatus are the same as those followed by the chemist in the laboratory, with only such modifications as are necessary to suit the conditions.

Eleventh: This arrangement of settling tanks permits an accurate daily report to be kept of the amount of water evaporated in the boilers.

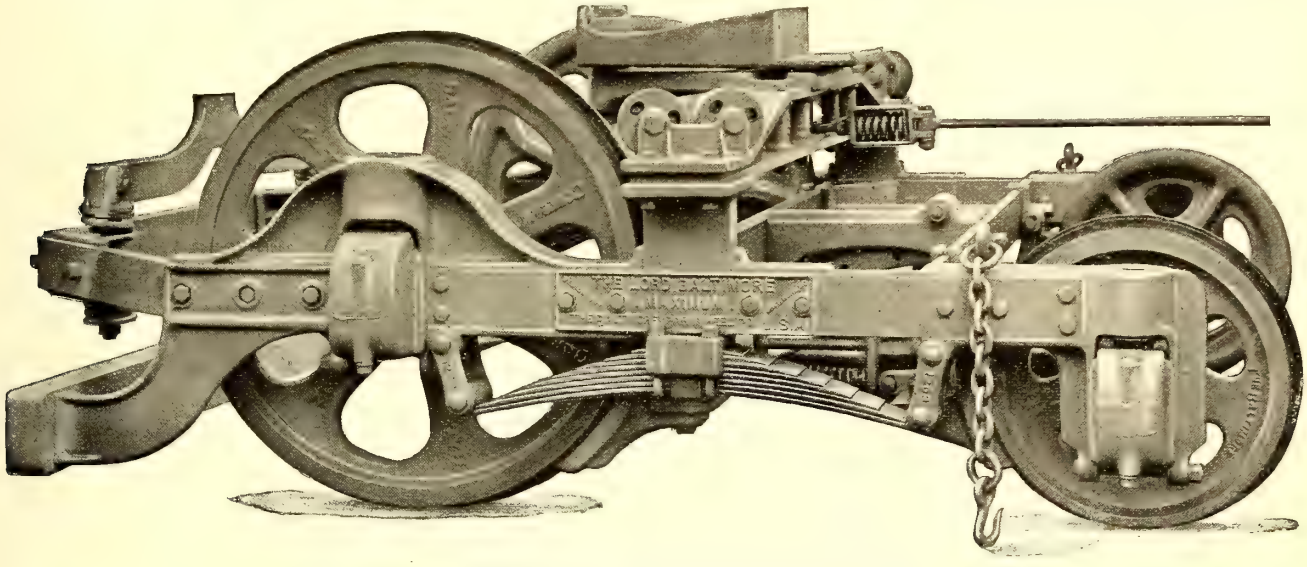
Inasmuch as it is not practical to use settling tanks having capacities sufficient to permit the water standing long enough to perfectly clear itself, we advocate passing the water through a mechanical filter, merely to clarify it by removing the floating lime sludge. For this purpose all that is necessary is to employ gravity or pressure filters, and use a sand-bed as a filtering medium. By this means perfectly clear, soft water is obtained.

There are twenty-three water softening plants in this country, erected in accordance with the most approved plans. These plants are furnishing softened water for ice factories, dye works, laundries, electric light plants, street railway power houses, steel works and various manufacturing concerns, some of which have been in daily use over three years, and all are giving most satisfactory results. The illustration shows a 2,000 h.p. water-softening plant, which has been in service since April 26, 1896, at the Columbus Central Railway Plant, Columbus, Ohio. It was installed by the We Fu Go Company, of Cincinnati, which controls the sale of these plants.

The following is an analysis of the raw water from the wells of that company, before softening, in grains per U. S. gallon:

Silica	1.25
Oxide of iron	4.250
Carbonate of lime	10.650
Carbonate of magnesia	5.325
Sulphate of lime	5.525
Chloride of soda	.670
Total residue	27.675

A sample of the softened water from the plant while in actual service, was sent to Professor Webber, of Ohio State University, in May, 1896, and was analyzed by him, and found to contain the following impurities in grains per U. S. gallon:



Silica	1.067
Oxide of iron	None
Carbonate of lime	1.508
Carbonate of magnesia	0.202
Sulphate of lime	1.609
Chloride of soda	None
Soluble salts (sulphates and chlorides of sodium and potassium)	8.490
Total residue	12.876

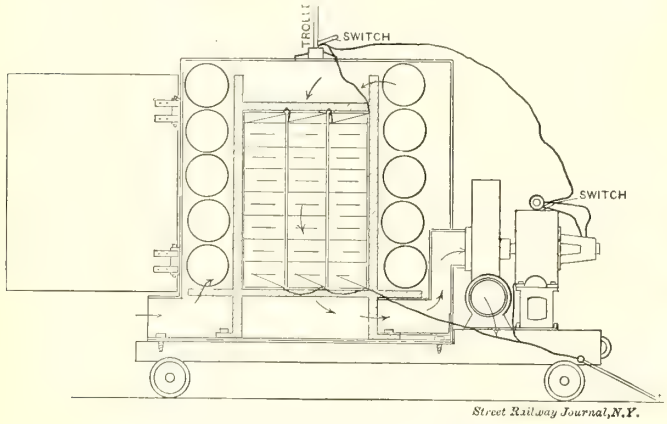
The Tramway Company of Brussels reports for the eleven months ending Nov. 30, 1898, gross receipts, 4,838,402 francs; number of car kilometer, 6,183,939. A little over 40 per cent of the car kilometer run was by electric cars.

Maximum Traction Truck

The illustration accompanying this article is the latest design of a maximum traction truck of the Lord Baltimore type, manufactured by the Baltimore Car Wheel Company, and of which some particulars were published in the last issue without illustration. The design of the truck is such as to bring 66 per cent of the weight upon the driving wheels, without it is claimed any liability of derailing the small wheels. The metal bolster centre plates, as shown, may be pivoted directly above or near the centre of the driving axle; the body bolster centre plate at its front end is recessed to receive the main car body bolster, to which it is secured by bolts through the base and end. Double taper roller side bearings are provided, as shown, upon which the chafe plates of the body press. These rollers are self-oiling, by being made hollow, and packed with saturated waste, and revolve upon steel thimbles.

The truck frame is made up of cast steel pedestals, having housings for graduated spiral springs, which rest on top of the journal boxes, so that the entire load is cushioned. The side members are bolted directly to the pedestals, and are diagonally braced securely between the wheels. The end cross bars are bolted to the main pedestals, and are drawn in at an angle to support the suspension bars, so that in curving these members do not come outside the rail. The truck is so designed that the motor is mounted outside the driving axle. There are two half elliptic springs suspended below the side frames by links, and to which the weight of the body and load is transmitted by steel flat-posts depending from and secured to the truck bolster, which play in guides formed by the bars of the side frames.

LORD BALTIMORE MAXIMUM TRACTION TRUCK



The brake mechanism is so designed that the shoes are applied to the inside of the wheels, and the levers are so proportioned as to bring about 70 per cent of the braking power upon the driving wheels. The brake beams are operated by levers, acting from the pivotal point of the truck; the top end of the operating lever works in a channel in the base of the truck bolster centre plate, so that they are always held in line and no quadrant is required for operating the brakes on curves. Spiral springs are introduced in the brake rods between the trucks, which equalizes the braking power on each truck, so that each wheel receives its proper proportion of the braking force.

All the working parts of the brake mechanism have large bearings with steel thimbles and suitable oil holes, and are placed at the centre line of the trucks, out of the way of mud and dust thrown up by the wheels. These trucks have all the stability claimed for centre bearing trucks of most approved design with the advantage of maximum weight available for traction. With the exception of the brake shoes and wheels, all parts are of steel and malleable iron; and in the design, special attention has been given to relieving the shearing strain upon the bolts. Dust-proof and oil-tight axle boxes are provided, in which either felt or waste feed may be employed as desired. The care and thoroughness with which the trucks are built is in keeping with all the products turned out from this well-known establishment.

The Barcelona (Spain) Tramway Company has petitioned for a number of additional rights for extending its trolley system.

Portable Hot-Air Blower

The accompanying engraving shows an interesting portable hot-air blower for drying armatures and fields, invented by W. R. Gaither, auditor of the South Chicago City Railway. The importance of keeping the insulation of these parts of an electrical

PORTABLE HOT AIR BLOWER

motor dry, and the advantage of doing this artificially after the motors have been in service on a wet day, is generally recognized by repair men, but the trouble and expense of removing armatures and fields from the casings and transporting them to a drying oven are so considerable that it is not often done. It is to simplify this process that the portable blower illustrated is intended.

The blower, which is mounted on flat wheels and is adapted to be drawn by hand, is brought alongside of the cars in the car house at night, over the pits as they stand. The blower is equipped with electric heaters and blowers, and has a trolley for making contact with the overhead wire. Upon reaching the car the blower is put in operation and the hot air is blown through the nozzle directly into the motor casing so that it acts directly on the armature and field insulation, accomplishing the same results as if the armature and fields were dismounted and transported to a stationary oven. Mr. Gaither estimates that it will require only 6 h.p. to generate 200 deg. of heat in a volume of air discharged from the nozzle at a rate of 300 cu. ft. per minute. This would reduce the cost of current for operating the device to about 50 cents for ten hours' use, and he thinks that in very wet weather the blower would pay for itself in a very short time in preventing burn-outs, especially with the open style of motor.

The special advantages claimed for the device are: First, that no extra labor in drying out armatures and fields is required, as the device takes only a few minutes and no skill to operate it or move it; second, the blower is valuable anywhere that current can be obtained, and of course wherever there are cars whose motors should be dried out, this condition prevails; third, the blower is portable and cleanly; fourth, it can be used without the heaters if desired, to blow out dust and dirt from the motors; fifth, the heat can be regulated to any degree, so that quick or slow drying can be secured.

Boiler Tube Cleaner and Flexible Shaft

The device illustrated in the engraving herewith is for the purpose of removing scale from the tubes of boilers of the water-tube type. The cleaning device consists of a conical shaped head, having a taper of about ¾ in., and composed of discs, with pivoted arms between each pair. At their outer extremities, these arms carry tooth cutters about 1⅛ ins. in diameter, and these arms with their cutter discs are set spirally in the head. A series of guide bars placed on the shaft back of the head not only serve to guide the tool in the tube, but provide bearings in which the operating shaft revolves. In the process of cleaning, the cone which is somewhat smaller than the tube, is inserted, and given a rotary motion up to about 1600 r.p.m. The centrifugal force causes the arms to fly out, bringing the cutters by the impact of vibratory movement in contact with the scale on the walls of the tube. This action causes the teeth to cut into and disintegrate the scale, which is then flushed out by means of a stream of water that is fed continuously into the tube by a hose as the process goes on. The cutting wheels not only remove scale, but when it is removed lose their vibratory motion and simply burnish the tube, and do not injure or expand the tubes, no matter how thin they are. The effect of burnishing the tubes after cleaning, serves to polish the interior by removing even the mill scale and so makes it impossible for scale to adhere

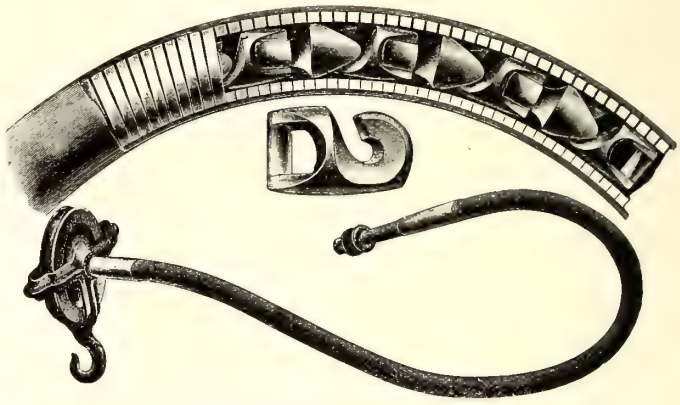


FIG. 2.—CLEANER FOR CURVED BOILER TUBES

tenaciously. This renders subsequent cleaning relatively easy, while it adds greatly to the efficiency of the boilers, by improving the circulation, increasing the radiation, and thus economizing in fuel consumption. The head is adjusted in the tubes by means of a sectional rod united by snap couplings. The rod is given a rotary motion by means of a driving pulley, having a sleeve with a key way through which the rod slides, and by means of a handle at the outer end the operator can move the head at will back and forth in the tube, while the rotary motion continues.

For cleaning curved tubes, a flexible head of the same shape

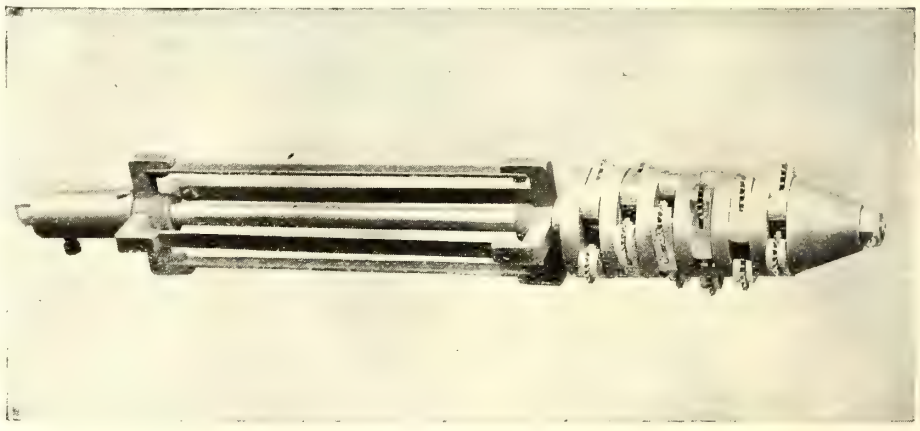

FIG. 1.—HEAD FOR BOILER CLEANER

and a flexible shaft are employed. This shaft, as shown in Fig. 2, is composed of solid brass links of peculiar shape, which hook into each other, and in turn are enclosed in a closely fitting spirally wound tube, which is flat on the inside, and provides a smooth bore in which the link chain operates. The whole is then encased in a tube of specially prepared rubber which is not effected by oil, which allows for oil lubrication of the flexible shaft, while it protects it from the flushing water, which is led into the tube in the same way as described for the straight shaft.

The tube cleaner and shaft are manufactured by the Union Boiler Tube Cleaner, whose works occupy part of the Imperial Power Building, 240 Penn Avenue, Pittsburgh, and which is equipped with a very complete assortment of metal working tools. The tube cleaner was put on the market in 1895, and the company has received many flattering testimonials as to its efficiency, and guarantees that it will sustain all the claims made for it. It is the practice of the company either to sell the tube cleaning device outright, or rent it to steam users by the year. The company also contracts to clean boilers for a stipulated sum per horse power. In all cases where a sale or lease is effected, an expert is sent without charge to install the device and give instructions for setting up and using. With this machine a man can clean from twenty to fifty tubes a day, depending upon their condition, and whether it is the first or second cleaning.

The use of the flexible shaft, which the company manufactures, is not confined to the operation of the tube cleaner, but may be employed in any situation where power is to be transmitted, or has been transmitted by any other type of flexible shaft. It is stronger in construction than most shafts of this character, and is especially adapted for use with portable electric motors for drilling or reaming bond or bolt holes in track rails or steel plates of any description.

A New Type of Cast Welded Joint

The application of the system of cast welding in rail joints has become so general that any new methods of cast welding the ends of rails are matters of public interest. The accompanying engravings illustrate a new type of cast welded joint brought out during the late fall of 1897 and the season of 1898 by the Milwaukee Railjoint & Welding Company, of Milwaukee, Wis. As will be seen, this joint differs from other cast welded joints both in form and substance. It extends along the sides of the rail for about 15 ins., and projects out at the joint of the rail, but not below the rail. It is composed of both cast iron and steel and is put upon the track by cleaning a small space around the rail joint about 2 ft. square down to the top surface of the ties and by cleaning the rail ends by the use of sandblast. A steel sleeve, shaped so as to form a cavity around the rail ends, is then riveted upon each side of the rail at the joint. After the rail ends have been heated, this sleeve is filled with melted iron. The latter fuses to the web and flanges of the rail and the steel sleeve, making a solid joint composed of both steel and cast iron.

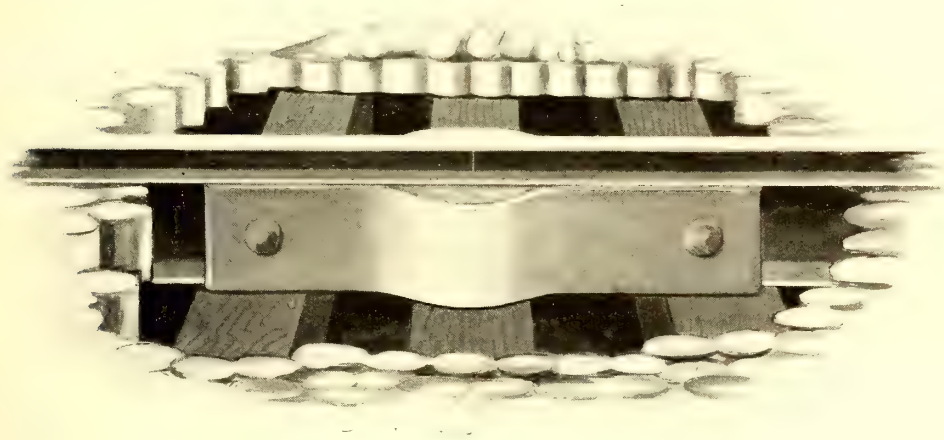

FIG. 1.—SIDE VIEW OF JOINT

As will be seen from this description but little work is required on the part of the street railway company in preparing its track for cast welding on joints upon this system. It is not necessary to remove or displace any ties. The roadbed is not disturbed, and the blocking removed from around the joint is quickly replaced.

About half a mile of track was welded with these joints in the late fall of 1897 upon the line of the Milwaukee Electric Railway & Light Company, of Milwaukee, and during the year 1898 ten thousand joints were welded upon the lines of the same company, including the welding of a suburban line from the city of South Milwaukee to the city of Milwaukee, a distance of about eight miles of exposed track. On this line to South Milwaukee a joint was used at distances from 500 to 1000 ft. to provide for the contraction and expansion of the rails where they were exposed; but subsequent welding on other lines of exposed rail demonstrated that it is not necessary to have a slip joint in order to make a cast welding of rail joints upon exposed track. The work being properly done, these joints will hold as well on exposed rails as upon embedded tracks, and the contraction and expansion seems to be entirely overcome by the strength of the joint.

This method of joint also seems to afford a perfect electrical bond. The electrical conductivity of the line welded between the city of South Milwaukee and the city of Milwaukee, by tests made by the Milwaukee Electric Railway & Light Company, varied from 118 per cent to 126 per cent, thus exceeding the conductivity of the rail itself from 18 per cent to 26 per cent, being the highest conductivity upon record given to any electric rail.

The success of the joint is proved by the work it has done, the welding made in the late fall of 1897 having stood to the present time without a single joint breaking, and the percentage of breakage upon the 10,000 joints welded during the year 1898 has been less than one-half of one per cent.

In the spring of 1898 the Milwaukee Electric Railway & Light Company gave to the Milwaukee Railjoint & Welding Company

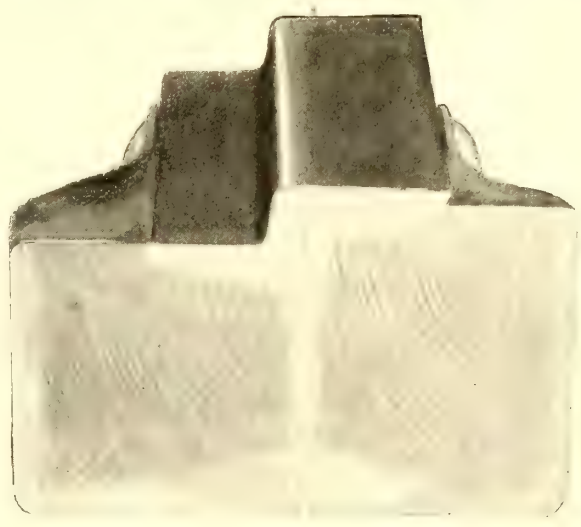

FIG. 2.—SECTION OF JOINT

a contract for 1,000 joints, and in the summer another contract for 10,000 more joints, and when these were completed, gave it a contract for 1899 for 20,000 joints, which will complete the welding of the entire system of the Milwaukee Electric Railway & Light Company in the city of Milwaukee, it having had welded, during the season of 1896-97, about 15,000 joints made by another company.

One of the cuts herewith shows the joint longitudinally as it looks upon the track, with the necessary paving cleared away to enable the making of the joint. (Fig. 1.) Fig. 2 shows a sectional view of the joint sawed one-half of an inch from the meeting of the rail ends. It shows the steel jacket around the outer part of the joint, the web of the rail in the center united to the cast-iron filling, which is fused to the rail web and flanges and to the steel jacket around the joint.

The Milwaukee Railjoint & Welding Company reports a very encouraging outlook for a large amount of welding during the season of 1899. It has its own patents, which, the company claims, cover very broadly this form of joint.

A New Repair House

The Advance Electric Company, which is an old established supply house in Indianapolis, has opened a department for the repair of street railway motors and other electrical apparatus. The company has engaged as foreman of its shops, David Fryer, a man of eighteen years' experience in this class of work, and whose ability and skill are recognized by many electrical men throughout the Central States.

The company tests all its windings and coils before sending them out, and is proud of the fact that in a long experience in the lighting field, it has never yet had a single piece of work returned on account of bad workmanship. Eighteen years' experience in the shop has bred a familiarity with every type of machine on the market, and the company keeps constantly on hand armatures and field coils for all the standard machines.

Located in Indianapolis, one of the best railroad cities in the Central States, the shipping facilities of the new company are unexcelled. The company's standard is best work and best material at moderate prices. The company has lately been reorganized with increased capital and is able to do street railway repairing on a large scale. Harry B. Marsh, the newly elected president, and Charles H. Talmage are in charge of the active management, and the reputation of these gentlemen is a guarantee that their work will be satisfactory.

A street railway company of San Diego, Cal., is using salt water for sprinkling its tracks. Electric sprinkling cars are employed.

New Combination Car of the California Type

The Brooklyn Heights Railway Company has just put in operation a new car of the California type, which, from its large size and arrangement of details, is of considerable interest. It is very similar in general appearance to the large cars recently put in service by the Metropolitan Street Railway Company of New York, but differs from them in several important details.

The first thing to be noticed is the fact that there is no step on the sides of the closed body of the car, and the body has no hand-rail. Experience with other cars of this style showed that this was a very necessary and important change. In the cars previously built for the Metropolitan Railway by the Brill Company, the sill ran through from crown-piece to crown-piece. This, of course, raised the rear platform, or that of the closed end of the car, very high, and considerable difficulty was found when old people and children attempted to enter. In the new car the sills run only to the end of the body, and the platform is dropped in the usual way, by the use of platform knees. This slight alteration brings the platform down practically as low as that of the open car, enabling it to be reached by a step only 13¾ ins. from the rail, with a 13-in. riser. All the new cars now in course of construction for the Metropolitan road are also having this change introduced.

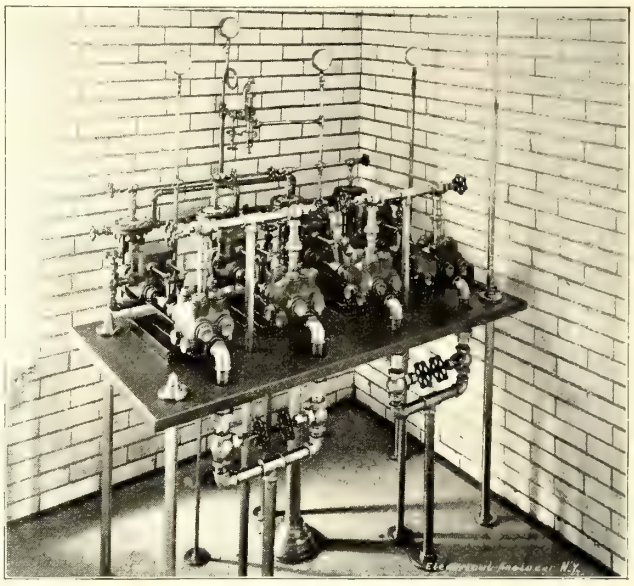
The length of the car over the corner posts is 36 ft., the length over the buffers being 44 ft. It is 6 ft. 6 ins. wide at the sills and 7 ft. 2 ins. at the post. On the front or open end of the car the platform is 3 ft. 8 ins. Ample strength is secured for the side sills by plating them with iron. The closed section is 11 ft. 2 ins. over the end panels, and has two double doors. The open section has seven cross seats, two of which, setting against the forward bulkhead, have stationery backs. Along the open portion there are the usual folding steps at the sides. These steps are 18½ ins. from the ground, with a 13-in. riser. The height in this case from the head of the rail to the under side of the sill is 28 ins. Brill maximum-traction trucks with a 4 ft. wheel base are used under the car. The wheels are respectively 30 in. and 20 in. in diameter. There are two w.p. 50 motors.

The ends of the car are provided with angle-iron buffers, and gates are used on one side of the rear platform, with a Brill folding gate on the opposite side. The seats in the closed compartment are longitudinal and covered with spring rattan, seating fourteen passengers; the open portion accommodates thirty-five, making a total of forty-nine seats. The closed compartment is finished in

COMBINATION CAR IN BROOKLYN

cherry throughout, with three-ply quartered oak ceilings. Cherry and ash are used for the finish in the open section.

Push-buttons are placed on each post, to signal the conductor. There are two 12-in. Dedenda gongs with disappearing buttons. There are two sand-boxes. The headlights are in the dasher. The trolley board extends the whole length of the car. The grab-handles of the posts are of ash, set in solid bronze sockets. Each of the seats in the open part of the car is fitted with a Brill round-corner seat end panel; by their use it is possible to bring the curtains down to the floor without catching or tearing—a feature which renders the open part of the car dry and comfortable in storms, and is one of the reasons why cars of this class are being so favorably received.



The weight of the car without motors is 17,200 lbs. The trucks weigh 3,250 lbs. each. The California car, with the modifications which are going on in its design and construction since its introduction in the East, is rapidly coming into favor wherever a large traffic has to be accommodated.

The Compagnie des chemins de fer sur routes, of Algiers, has ordered eight new cars with double Walker equipment and Dickinson trolley.

Automatic Lubrication

The economy of power generation in an electric railway system is often the determining factor in the financial success of the road, and the modern power station is equipped with every device which tends to reduce the operating cost. Among the many minor improvements in this line there is none which has met with greater favor, perhaps, than that of the automatic oiling of the wearing parts, for it not only reduces largely the labor of attendance, but provides a sure and cleanly system of lubrication.

A very ingenious, but simple and effective, system of oil distribution is that used in the power station of the Missouri-Edison

PUMPS FOR LUBRICATORS

Electric Company, of St. Louis. The system was designed by the Siegrist Lubricator Company, of that city. The oil is circulated under pressure, and the arrangement of the pumping apparatus is shown in the accompanying engraving. These pumps, which are four in number, are of the smallest size of duplex steam pumps, were especially designed for this work, and are mounted on a slate-top table in a corner of the engine room. The pumps are connected in pairs, and one of each pair serves as a relay. One pair is designed to pump the engine lubricating oil, and the other the cylinder oil. The oil is pumped to the different bearings, where the sight feed-oil cups are located. The rate of drip from each oil cup can be regulated at will by a thumb screw, but the piping system is so arranged as to close the drip feed if the pressure on the piping system is lowered more than 2 lbs. The only thing required then to control the oiling system is to open or close the one globe valve placed in the main oil-supply pipe The closing of this valve stops the oil at every oil cup within a few seconds, thus preventing any waste of oil after the engine is stopped. The oil is piped back from all drips of the engines and generators to filters located in the basement.

The cylinder oil is controlled in the same way as the engine oil, through sight-feed lubricators for each cylinder, placed at a convenient height from the floor. The pressure maintained in the cylinder lubricating system is, of course, slightly higher than the steam pressure.

The lubricators employed in the system are illustrated in section in the accompanying engravings. Fig. 2 shows an ordinary pressure oil cup, which is placed in the same position as an ordinary oil cup. The opening D connects with the feed. As soon as the oil enters the cup it acts upon the diaphragm, raising the small valve from the seat C, thereby allowing the oil to flow in drops or in a stream, according to the wishes of the engineer, who can regulate it by the small regulating screw A. When the pressure is relieved the valve automatically closes the cup, as already described, preventing the waste of oil.

The cylinder-lubricator is illustrated in Fig. 3. This device is screwed in the steam pipe in the same position as the ordinary lubricator, and the opening D is connected to the cylinder oil-pipe line by a small ¼-in. pipe, so that the lubricator would be supplied with cylinder-oil under pressure. As soon as the oil enters the

lubricator it acts on the diaphragm B, lowering the small valve from the seat C, thereby forcing the oil in drops or in a stream up through the water in the sight-feed glass and into the steam pipe, to be carried by the steam into the cylinder of the engine. The rate of feed in this cylinder can be regulated by the screw A. The

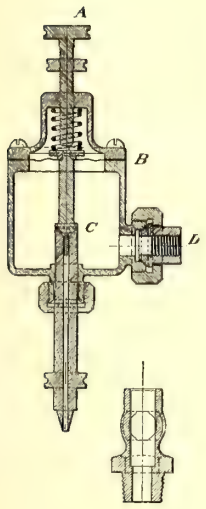


FIG. 2

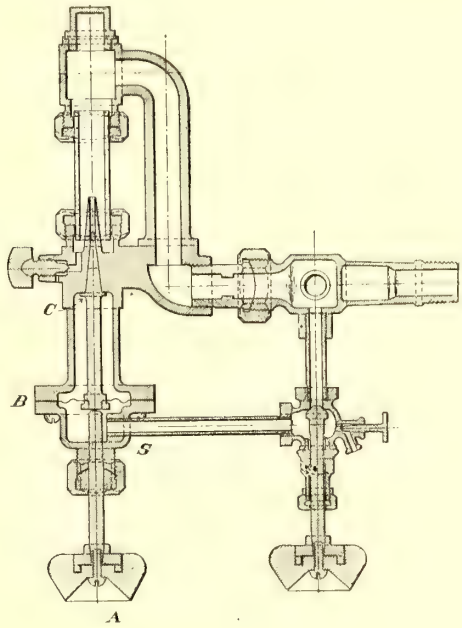

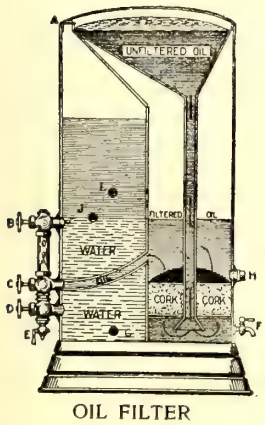

FIG. 3

steam connection shown beneath the diaphragm acts instantly to close the valve in case the oil pressure should fall below that of the steam, thus keeping the glass free from oil.

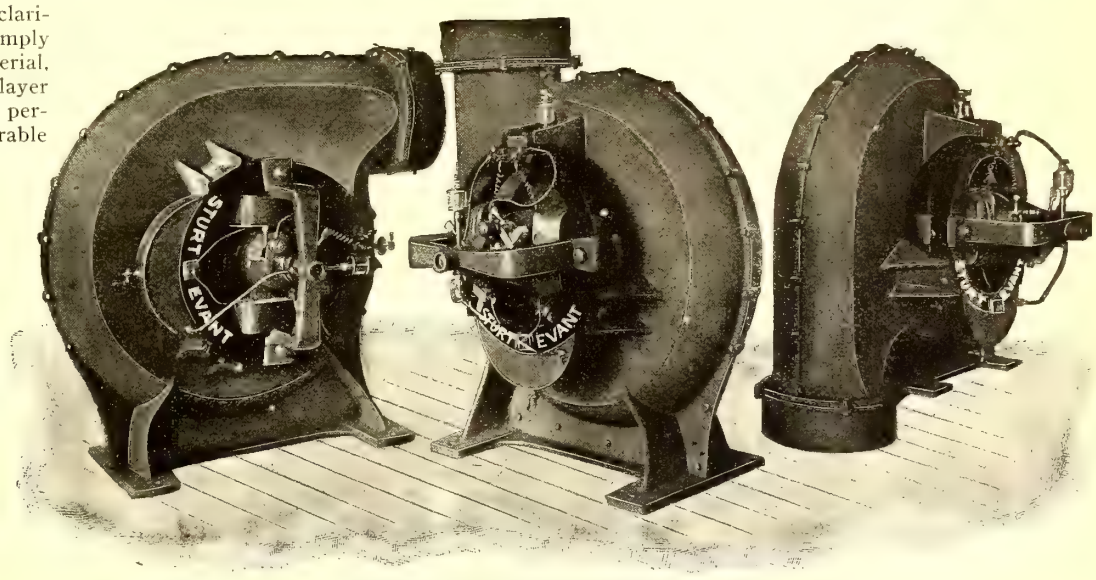
Oil Filters

The handsome oil filters of the Kosmic Oil Filter Company, of Easton, Pa., are now found in many of the largest power stations throughout the country. In this filter the oil, instead of being clarified by passing downward simply through some straining material, is passed upward through a layer of cork, and, in addition, is permitted to rise for a considerable distance through a body of water, this latter process effectively removing all impurities that might possibly make their way through the cork.

OIL FILTER

As will be seen from the cut, a partition divides the filter into two compartments, this arrangement possessing the advantage of enabling one part to be cleaned without interfering with the other. By regulating the center valve, which controls the flow of oil from one compartment to the other, the degree of purity can be seen as it passes up through the water in the glass tube, and the whole process can be regulated by the engineer in charge according to the purity of oil desired.

Carbon Brushes



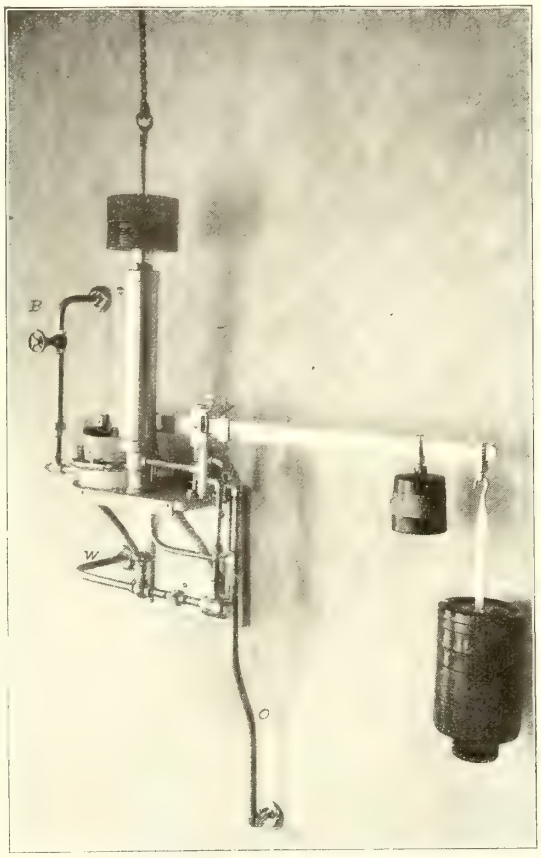
A treated carbon brush for motors, generators and dynamos, especially designed for saving the commutator, is manufactured by the Le Valley Vitæ Carbon Brush Company, of New York. This brush has come into very extensive use, and numerous testimonials to the satisfaction given by it are being received, one street railway company writing that the Vitæ brush had run nearly 19,000 miles on one of its street railway motors. Although these products have been in use for only two years they have been adopted as standard by a number of leading street railway and electrical companies after severe tests.

The manufacturers claim that the Vitæ brush does not cut or wear the commutator, that it wears many times longer than other brushes on the market, is thoroughly self-lubricating, never gumming the segment tips, requires little attention, runs from 7 to 10 deg. cooler than other brushes, and having great conductivity it conveys the current without loss; and, further, that it leaves no deposit of dust in the motor, which is one of the causes for short circuiting.

Special Types of Electric Fans

The rapid development in the employment of electric fans for ventilating and other purposes, has led the B. F. Sturtevant Company, of Boston, Mass., to prepare special designs suitable for special conditions. The shells of those illustrated are of cast iron, like the regular monogram blowers and exhausters manufactured by this company. The one upon the left, as is evident from the position of oil cup and oil tank, is designed to be attached to a vertical wall, and to discharge directly upward. That at the centre may be placed upon the floor to discharge in the same direction, while that upon the right is designed for vertical downward discharge.

The motor is of the bi-polar type, the field rings and pole pieces being of wrought iron, and the frame accurately centered and held securely in place by bolts introduced through lugs projecting from the side of the fan. The general internal construction consists of drum-wound armature, having a commutator with ample brush surface, and of reaction brush holders with fibre graphite brushes. Yokes extending from either side of the field ring, and provided with ring oiler boxes, serve to support the armature shaft. All trouble from oil is avoided by conducting the overflow through tubes to the small receiving tank beneath and attached to the field ring. Fans of this type are built in sizes ranging from 18 ins. to 6 ft. high, and designed to deliver air under pressure ranging from 1 oz. to 5 ozs.



SPECIAL TYPES OF ELECTRIC FANS

An instance of the progressiveness of the technical press was recently shown by "Lomotive Engineering" of New York. This paper's entire editorial office was burned out in the recent Home Life Insurance Building fire, and yet the paper appeared very nearly on time with its usual amount of valuable and interesting matter. This necessitated almost superhuman efforts on the part of the editors and managers, and they are certainly to be congratulated upon their success.

Improved Hydraulic Damper Regulator

A machine for accurately regulating the steam pressure of boilers by regulating the admission of air to the fires through the dampers is shown in the engraving herewith. This regulator can be easily erected in the boiler or engine room and connected to the dampers to control from one to twenty boilers.

Referring to the illustration, B is the steam pipe connection coming through the wall from the boilers, W is the water connection for supplying the water that operates the damper motor. and S is a strainer to prevent foreign matter from getting to the damper water valve. By unscrewing the cap at the end of the strainer any collection of matter can be cleaned out without breaking the pipe

HYDRAULIC DAMPER REGULATOR

connection. The overflow pipe for carrying off the discharge water is shown at o. The valve controlling the water passing to and from the damper motor is operated by a lever, to which weights are attached, and by placing the proper weights upon the lever, the regulator can be set to close the dampers at any desired steam pressure. The machine can also be used for testing steam gages without removing them from the boilers.

All the parts of the apparatus have been carefully designed from a scientific and engineering standpoint, and it is claimed that for simplicity of construction, neatness in finish and sensitiveness in operation this regulator is not surpassed by any other on the market. It is guaranteed that a change of one-half pound to the square inch of boiler pressure will open or close the heaviest dampers. The apparatus is made by the Patterson Damper Regulator Company of Baltimore, Md., and was designed by George F. Patterson, president of the company, who has been for many years almost exclusively engaged in handling damper regulators, and is, therefore, well acquainted with the requirements.

The Increasing Demand for Car Fenders

The danger to life and limb incident to the increased speeds at which electric cars are now run through crowded city thoroughfares as well as through less densely populated suburband and interurban districts has brought very forcibly, and often very painfully, to the minds of street railway general managers the necesity of equipping their cars with proper and efficient life-saving devices Up to a comparatively recent period, fenders, if used at all, were generally added as an afterthought, whereas now they are rapidly coming to be considered a nearly indispensable part of the equipment, and are often given considerable attention in the specifications for rolling stock.

The magnitude to which the car fender business has grown is shown by a recent report of the Consolidated Car Fender Company, of Providence, R. I., manufacturer of the Providence fender. Since starting in business four years ago, this company has equipped 5000 cars with its device, and the Providence fender is now in practical use in more than eighty cities and towns in the United States and Canada. The Metropolitan Street Railway Company, of New York, has alone purchased 1188 equipments.

The Consolidated Car Fender Company reports that orders and inquiries already received this year clearly indicate that the demand for its fender during 1899 will far exceed that of any previous year. Among the orders just completed are fenders for all the motor cars of the Auburn City Railway Company, Auburn, N. Y.; the Middletown-Goshen Traction Company, Middletown, N. Y.; the South Chicago City Railway Company, Chicago, Ill., and the Van Brunt Street & Erie Basin Railway Company, of Brooklyn, N. Y. A large number of Providence fenders were also recently furnished the Ottawa Car Company, Ottawa, Ont., and will be placed on new cars now being built for street railway companies in Canada. The Consolidated Company is daily receiving orders from one or more of the many roads using its device for new equipments to be placed on new cars that are being added to the various systems. The business received in this way alone is sufficient to keep its factory running full time without the new business that is continually coming in. In order to fill all demands promptly, it is found necessary to carry in stock not less than 1000 full equipments.

The steady and rapid growth of the business of the Consolidated Car Fender Company is a practical illustration of making "the best" regardless of the first cost.

Personal

MR. S. DANA GREENE has been appointed general sales manager of the General Electric Company.

MR. A. E. BURLAND, superintendent of the Newport Street Railway Company, of Newport, R. I., on Dec. 25, was presented a testimonial of esteem by the employees of the line.

MR. F. P. MOONEY has resigned his position as general superintendent of the Cortland & Homer Traction Company and the Cortland & Homer Electric Company, of Cortland, N. Y.

MR. H. A. EVERETT has been elected president of the Cleveland Electric Railway Company, of Cleveland, Ohio, in place of Mr. H. E. Andrews. Mr. Charles L. Pack has been appointed vice-president.

MR. O. M. RAU, chief electrician of the Milwaukee Electric Railway & Light Company, will temporarily fill the position of superintendent of the lighting department, in place of S. G. Coleman, who recently resigned.

MR. HENRY N. RANSOM, who is well known in the street railway field as New York representative of the Consolidated Car Heating Company, will soon be married to Miss Gillet, daughter of Mr. Ainslie M. Gillet, of Albany.

MR. T. H. ANDERSON has been elected general manager of the Somerset Traction Company, of Skowhegan, Maine, to relieve Mr. R. B. Shepperd, the president of the road, who has heretofore held the title of general manager also.

COL. EUGENE GRIFFIN, of the Volunteer Engineer Corps, and first vice- president of the General Electric Company, was recommended last month for appointment as Brigadier General, for valuable service rendered in Porto Rico during the late war.

MR. J. M. SHENK has resigned from the presidency of the Lebanon & Annville Street Railway Company and the Lebanon & Myerstown Street Railway Company, both of Lebanon, Pa., on account of other duties requiring his attention. Mr. S. P. Light was elected president in his place.

MR. H. F. PARSHALL, of London, has secured the gold medal of the British Institution of Electrical Engineers, for his paper on "Earth Returns for Electric Tramways," delivered before the Institution on April 28, and reprinted in the Street Railway Journal for June, 1898, page 322.

MR. F. C. ARMSTRONG, engineer with Dick, Kerr & Company, Ltd., of London, was married on Jan. 11, at Cobourg, Ontario, to Miss Helen R. McCallum, of Cobourg. Mr. and Mrs.

Armstrong sailed for Liverpool on the steamship Teutonic, Jan. 25, and will live in one of the suburbs of London.

MR. CHARLES SHELDON has resigned the position of general manager and treasurer of the Consolidated Car-Heating Company, of Albany, N. Y., to become manager of the Chihuahua & Pacific Railroad, with headquarters at Chihuahua, Mexico. Mr. Frederick W. Kelley, who has been Mr. Sheldon's assistant, has been appointed general manager and treasurer of the Consolidated Car-Heating Company.

MR. WM. E. COOKE, representing the London syndicate controlling the tramways system at Perth, Western Australia, arrived in Perth late in December and commenced immediately upon the work of converting the horse tramways to electric. He states that owing to the heat of the climate, the hilly nature of the city, the badness of the roads and the large and scattered area within the city boundaries, Perth is an excellent street railway city.

MR. J. W. HICKS, superintendent of the Rochester Railway Company, and Mr. Thomas Hicks, assistant superintendent, were very pleasantly surprised by beautiful gifts from employees of the road, at Christmas time. These gentlemen are very popular with the company's men, and to show their esteem the employees raised a fund and presented Mr. J. W. Hicks with a handsome parlor cabinet of solid mahogany, and Mr. Thomas Hicks, with a fine easy chair of solid mahogany.

MR. W. R. MASON, who was representing the Walker company at St. Louis at the time of the consolidation of that company with the Westinghouse, has been appointed manager of the St. Louis office of the Siemens & Halske Electric Company. Mr. Mason is well known in the street railway field, and his large acquaintance, railroad experience and characteristic energy and perseverence would naturally make him a valuable acquisition to any company closely identified with the electric railway or lighting interests which secured his services.

EX-BALLIES H. CRAWFORD, THOMAS MASON AND MICHAEL SIMONS, ex-members of the town council of the city of Glasgow, Scotland, and Mr. J. Murry Smith, of the "Glasgow Evening News," are in America, and will visit a number of the principal cities of this country. The main object in making this trip is to interest the American Government in the International Exposition to be held in Glasgow in 1901. This exposition will afford American manufacturers an excellent opportunity to exhibit their goods to the Scottish people, and advantage will undoubtedly be taken of this opportunity by a large number of firms. The gentlemen from Glasgow will also pay particular attention while in America to electric railways, and will inspect a number of prominent systems.

MR. JOHN E. ANGER, recently with the John Stephenson Company, Ltd., has accepted the position of master car builder of the Electric Railway & Tramway Carriage Works, of Preston, England. The formation of this company was mentioned in a recent issue of the STREET RAILWAY JOURNAL, and it proposes to do a large business in the manufacturing of tramway cars. Mr. Anger is well known in the car building industry in this country. He began his career in this business with the Gilbert Car Manufacturing Company, of Troy, N. Y., in 1869, and remained with that company until the close of the year 1876, when he accepted a position in the car building shops of the New York Central Railroad Company. He remained with this latter company for about five years, when he resigned to enter the employ of the Jones Car Manufacturing Company, whose factory was then located at Schenectady, N. Y. When these shops were leased by the Gilbert Car Company, Mr. Anger was offered a position with this company again as first foreman, but was soon promoted from one position to another until he was made superintendent of the Schenectady plant. When the Gilbert Car Manufacturing Company abandoned its Schenectady plant, Mr. Anger removed to the company's Green Island plant, where he was assistant to Mr. F. A. Stanley, then general superintendent. He remained with the Gilbert company until it became insolvent, when he accepted a position with the Jackson & Sharp Company, of Wilmington, Del., with whom he remained for about four years, or up to last spring, when he became associated with the John Stephenson Company, at its Elizabeth plant. He installed the entire machinery at the latter plant and remained with the Stephenson company until the middle of December, when he decided to accept the offer of the Electric Tramways & Carriage Company. Mr. Anger is forty-five years of age, and being naturally of an inventive turn of mind has made many improvements facilitating the construction of cars. He has also taken out a number of patents in the line of trucks and car seats, and at the present time is engaged on several other improvements in car building. He has always won the good will and best wishes of his employers and associates.

Obituary

MR. W. BARTLETT, chief engineer of the St. Louis & Suburban Railway Company, of St. Louis, Mo., died at his home on Jan. 16, 1899.

MR. E. K. STONE, for many years general manager of the Quincy Horse Railway & Carrying Company, of Quincy, Ill., died recently at his residence in Quincy.

MR. M. C. BULLOCK, for many years president of the Bullock Manufacturing Company, of Chicago, Ill., died in that city on Jan. 12. Mr. Bullock was born in 1838, at Granville, N. Y., and spent the early years of his life on a farm. Being attracted to the trade of a machinest, he served his apprenticeship in a shop near his home, and then traveled from State to State for the purpose of gaining wider experience in his chosen vocation. He was connected with a number of well-known manufacturing companies, and also did considerable engineering work, until 1878, when he started the Bullock Manufacturing Company. Through his tireless efforts this business was placed upon a successful basis, and he gradually broadened its scope until it included the manufacturing of rock drills, air compressors, hoists, diamond drills, steam engines of all kinds, etc., the latest being the Willans high-speed engine. Mr. Bullock has been failing in health for over a year, but his death was unexpected.

AMONG THE MANUFACTURERS

DICK, KERR & COMPANY, LIMITED, of London, have sold five Walker car equipments for the West Hartlepool Tramways, owned by the British Electric Traction Company.

MESSRS. McCLAVE & HAMILTON, of New York, are representing in New York and vicinity, James Bonar & Co., manufacturers of steam appliances, and the Pittsburgh Feed Water Heater and Engineering Company.

JOHN A. ROEBLING'S SONS' COMPANY, of Trenton, N. J., has published its new price list for all kinds of bare and insulated telegraph, telephone and trolley wires, underground cables, lamp cords, etc.

THE COLUMBIA INCANDESCENT LAMP COMPANY, of St. Louis, Mo., is sending out its new catalogue, containing five full-size reproductions of the various styles of direct and alternating-current incandescent lamps which it manufactures.

GEO. A. PARMENTER, Cambridgeport,, Mass., manufacturer of the Parmenter fender and wheel guards, reports that among other orders lately closed is one for the equipment of the entire system of the City & Suburban Railway Company, Washington with Parmenter fenders and wheel guards.

CARD CASE.—The Electrical Installation Company, of Chicago, Ill., general street railway contractors, are sending to their friends a very handsome and useful pocketbook and card case. The case is made of black leather and contains compartments for cards, papers, etc. This little souvenir will be heartily appreciated by all those fortunate enough to secure one.

PENCILINGS.—One of the daintiest catalogues of the season has just come from the press of the Dixon Crucible Company, of Jersey City, N. J. This little pamphlet bears evidence of most careful thought in its preparation, and tells in a very lively and interesting manner what the requirements of a good lead pencil are and how Dixon pencils fully fill all these requirements.

THE BIBBER-WHITE COMPANY, Boston, is sending to its friends a very acceptable souvenir, consisting of a combined calendar and thermometer for desk use. The Bibber-White Company reports that the past year has been an unusually good one in the street railway line for it, while business for the new year is starting off with a pace that bids fair to tax its present capacity.

THE BAKER HEATER, manufactured by Wm. C. Baker, of New York, claims to satisfactorily solve the problem of heating street cars, particularly long interurban cars. This system of heating was fully described in the last issue of the STREET RAILWAY JOURNAL, and the company reports that its apparatus is in use on a number of systems, and that inquiries and orders are being constantly received.

THE AMERICAN ENGINE COMPANY, of Bound Brook, N. J., has found it necessary, on account of the increased growth of its business, to establish a branch office in New York City. This office will be located in the White building, 95 Liberty Street,

and will be in charge of Edwin S. Boyer, formerly of Philadelphia. All orders or inquiries sent to the New York office will have prompt attention.

THE CARNEGIE STEEL COMPANY, LIMITED, Pittsburgh, Pa., has placed an order for 5000-h.p. Pittsburgh feed-water heater and purifiers for its new plate mill. This is the third order placed with the manufacturers of these heaters by the Carnegie Company, and is good evidence of the fact that they are giving good satisfaction. This makes 33,500-h.p. Pittsburgh heaters in the Carnegie plants.

JAMES BONAR & COMPANY, of Pittsburgh, Pa., have made arrangements for special agencies for the sale of their Pittsburgh feed-water heater and purifiers, Bonar gage cocks and Bonar oil filters for the New York territory, with Messrs. McClave & Hamilton, 141 Broadway, New York, N. Y., for New England, with F. W. Ashcroft, 63 Oliver Street, Boston, Mass., and for Mexico, with Robert J. Campbell, City of Mexico.

THE CHAPMAN VALVE MANUFACTURING COMPANY, of Indian Orchard, Mass., announces that it has a complete stock of Chapman gate valves for water, high and low pressure steam, gas, oil, ammonia, air and brine. This stock has been placed in Philadelphia, so that the trade and users of valves in the Middle Atlantic States can have orders filled without delay. The headquarters of this company in Philadelphia are at 40 North Seventh Street.

THE SPRINGFIELD MANUFACTURING COMPANY, of Bridgeport, Conn., has met with pleasing success in the introduction of its wheel-grinding machines. A number of these are now in course of construction, and several have been shipped within the last few weeks. Among these may be mentioned one for the Boston Elevated Railway Company, and one to South America. One of the grinders now building will go to a large road in Japan.

HEYWOOD BROTHERS & WAKEFIELD COMPANY, of Boston, Mass., among other contracts, recently supplied all the seats for the three handsome cars built by the Laconia Car Company for the Newton Street Railway Company, of Newton, Mass., and which were described in the last issue of the Street Railway Journal. These seats are of the Henry reversible type, and were chosen for their handsome appearance and strength and simplicity of construction.

LUNDELL MOTORS.—The Sprague Electric Company, of New York City, has published another of its elaborate and valuable catalogues for which this company is famous. This pamphlet is devoted to a detailed description of the Lundell motors and their application to Linotype machines, printing presses, metal and woodworking machines, elevators, horseless carriages, etc. The book contains a number of curves showing the remarkable efficiency of these motors.

THE M. MITSHKUN COMPANY, of Detroit, Mich., reports that its business has increased largely of late, and that prospects in general are excellent. The company has been established a long time, and is well known throughout the entire country. It is able to furnish at short notice steel rails of any desired weight, and these are kept in stock and ready for immediate shipment. The company also has on hand locomotives suitable for construction purposes, steam shovels, and other railway and contractors' supplies.

A GOOD LIGHT for night construction, shop work and heavy metal heating is a nearly indispensable part of the equipment of an up-to-date street railway. One of the best lights for this purpose on the market is the Wells light, manufactured by the Wells Light Manufacturing Company, of New York, and it has been adopted as standard by many of the leading railways and contractors of the country. It is being used extensively in the new conduit construction of the Metropolitan Street Railway Company in New York.

THE SIMPLEX ELECTRICAL COMPANY, of Cambridgeport, Mass., in its new catalogue for 1899 fully describes its very complete line of electrical heating apparatus. This company has gone very extensively into this subject, and manufactures heating and cooking articles of almost every conceivable description, including portable stoves, tea-kettles and stands, electric chafing-dishes, boilers, flat-irons and radiators, and heaters for waiting rooms and electric cars. The car heaters are in extensive use, and are giving good satisfaction.

ELECTRICAL SPECIALTIES.—The Sterling Supply & Manufacturing Company, of New York City, has issued its catalogue for 1899, and in this will be found descriptions of the numerous street railway "Sterling" specialties. These include registers, safety brakes, insulation, commutator bars, car fenders, sand boxes, etc. There is no line of goods in the street railway industry more widely or favorably known than the "Sterling" specialties, and the company reports an excellent business for the past months and splendid prospects for the coming year.

THE BERLIN IRON BRIDGE COMPANY, at East Berlin, Conn., has just shipped several carloads of bridge material to the Hawaiian Islands. It is believed this is the first American bridge that was ever put up in these islands. The contract for this bridge was obtained through the Berlin Iron Bridge Company's regular established agency located at Honolulu, and men will be sent from the United States to put up the bridge, which is for highway travel. It consists of one span of 200 ft. 40 ft. wide, and will be located across a river in one of the larger towns of the islands.

W. B. UPTON, who has been engaged as the principal assistant engineer of the Capital Traction Company, of Washington, D. C., in its work of changing its cable railway to the open conduit electric system and in the building of the new power station illustrated in the last issue of the Journal, has resigned from that position, as his work has now been completed. Mr. Upton has resumed his practice as consulting engineer, with headquarters in the Washington Loan and Trust Building, in Washington, and is making a specialty of open conduit electric systems, electric power stations and building engineering.

THE BONNER RAIL WAGON COMPANY, of Toledo, Ohio, is putting upon the market an express wagon so built as to be mounted on a truck adapted for electric railway track. Until recently three of these wagons have been running between Toledo and Bowling Green. They are connected up in a train, and are drawn by an ordinary motor car to distribution points. The rail wagon is then switched out of the main track, the wagon is run off the track, horses are attached, and distribution is commenced. On the return trip the wagon reaches the main track, is run upon the truck and taken in train to the central city. This system appears to have some advantages in special places.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, of St. Louis, Mo., on account of the increasing demand for its goods in the Northwest, has decided to establish an agency at Chicago. The agency has been placed in charge of George B. Foster, late of J. Holt Gates & Company, who will make his headquarters at room 1519, Marquette building, but will spend considerable of his time traveling through the territory of the Northwest, placing before the companies of this section many Wagner specialties. Mr. Foster's territory includes the States of Minnesota, Wisconsin, Iowa, Northern Michigan, the western part of Southern Michigan, the northern part of Illinois, and the northern part of Indiana.

MESSRS. J. G. WHITE & COMPANY, are the consulting engineers and purchasing agents of the Deep Leeds Electric Transmission Company, of Victoria, Australia, a company organized to erect a complete plant for supplying energy for all mining purposes to three mines in Victoria. Contracts have already been made for electric apparatus with the General Electric Company, for engines with the Buckeye Company, for boilers with the Babcock & Wilcox Company, for condensers and pumps for power house with the Wheeler Condenser & Engineering Company. The mine pumps themselves, which are to be mounted on the same bed-plate with the motors, but geared to them, are to be manufactured in Australia.

THE UNION ELEKTRICITATS GESELLSCHAFT, which owned the German rights for all the patents of the General Electric Company, of America, took possession on Jan. 1, 1899, of the electro-technical factory, operated hitherto by the Aktien Gesellschaft, Ludwig Loewe & Company, whose entire business consisted in manufacturing the apparatus required by the Union Company. Wilhelm Laue, formerly on the board of directors of Ludwig Loewe & Company, has become a member of the board of the Union Company, and will occupy the position of managing director. The Union Company announces that the large increase of its capital in manufacturing facilities enables it to comply most promptly with the steadily increasing requirements of its business.

THE WORKS of the New Process Raw Hide Company, of Syracuse, N. Y., were destroyed by fire Dec. 19, resulting in a complete loss of the plant. At the time of the fire the company was running overtime on orders. Since the day of the fire this company has been working with its characteristic hustle to get a new plant in operation, and will be ready to run again by the first day of February. The new works will be located at 305-309 North State Street, Syracuse, the business office remaining at 348 West Washington Street. The product of the New Process Raw Hide Company has become known in about every section of the world that there is machinery in operation. Its raw-hide pinions are

well known in the electric railway field for their lasting qualities and freedom from noise.

HERMANN HEINRICH BOEKER & COMPANY is the name of a new firm organized Nov. 15, 1898, in Berlin, the members of which are H. H. Boeker, formerly connected with the Bergische Stahl-Industrie, of Berlin, and Moritz Boeker, engineer, of Remscheid. The selling business of the Bergische Stahl-Industrie, which is primarily a manufacturing company, having become too large to be well taken care of under its own name, it has turned this business over to the new firm, which intends to furnish a medium between manufacturers and customers of different countries, to handle agencies, etc. For instance, the new firm has received of the Standard Air Brake Company, of New York, the exclusive right of selling its air brake equipments in Germany, and other agencies are desired.

LARGE ORDER FOR BOILERS.—The Babcock & Wilcox Company has received from Westinghouse, Church, Kerr & Company the largest stationary boiler order that has ever been placed. The boilers are for the power plant which the Westinghouse Electric Company have contracted to build for the Third Avenue Railroad Company, of New York, at 218th Street and Harlem River, and which is to be constructed by Westinghouse, Church, Kerr & Company. The order covers sixty Babcock & Wilcox forged steel-type boilers of 520 h.p. each, or an aggregate of 31,200 h.p. The boilers are to be capable of carrying 200 lbs. steam pressure. They will supply steam for compound condensing engines of 64,000 nominal h.p. in the aggregate. Further particulars of this order were published in the last issue of the STREET RAILWAY JOURNAL.

ARTHUR W. FIELD, of Boston, is doing an excellent business in the many street railway specialties for which he is agent. Mr. Field is now the representative in New England of a number of the most important manufacturing companies in the country, and represents the Peckham Truck Company, American Car Company, Ruggles' rotary snow plows, Price's friction brakes, Wheeler reflectors, Brandon metal paints, etc. In fact, Mr. Field is ready to supply practically anything which goes into the equipment of a company's rolling stock. By enterprise, ability and careful attention to the wants of his customers, he has succeeded in securing an excellent business. His recent calendar is extremely attractive. Mr. Field has also just sold, as New England agent for the American Car Company, fifty open nine-bench cars and thirty open twelve-bench cars to the Boston Elevated Railway Company, delivery to be made May 1.

J. HOLT GATES & COMPANY, Marquette building, Chicago, report the following recent sales: Armour Glue Works, Chicago, one 225-kw. 500-volt generator, two 150-kw. 500-volt generators, seven 50-h.p. motors, two 100-h.p. motors, two 150-h.p. motors, one 30-h.p. motor, two 25-h.p. motors, all made by the Card Electric Company, Mansfield, Ohio; Deering Harvester Company, Chicago, seven 500-light transformers, five 400-light transformers, three 200-light transformers; Elkhart Lake Electric Light Company, Elkhart Lake, Wis., two 10-h.p. single-phase motors and transformers and direct dynamos, attached to large storage batteries for electric launches, Armour Glue Works, Chicago; one $3,000 switchboard, Pierce & Robinson, Chicago; one $700 switchboard, residence of P. D. Armour, Jr., Chicago; one 300-light electric light plant, with Nash gas engine direct connected.

ONE OF THE handsomest souvenirs that has come to hand is being sent out by the United States Projectile Company, of Brooklyn. The souvenir is for use as a paper-weight, and is a six-pounder projectile such as was used so effectively by our navy at Manila, Santiago and other places, but has been nicely nickel-plated so it will not rust. To comply with the Government ballistic test one of these projectiles must penetrate a steel plate 3 ins. thick without showing a crack or fracture of any kind. The United States Projectile Company is well known to the electric railway field as manufacturer of the patent hot-pressed pinions, of which upward of 50,000 have been sold since their introduction. The company has a very extensive and model plant, and during the war with Spain the Government orders for projectiles kept the plant running day and night, almost to the exclusion of all other work, but the company reports that it is again prepared to fill orders with reasonable promptness for its well-known pinions.

WIRE GAGE AS A SOUVENIR.—A very convenient souvenir in the shape of a combination foot rule and wire gage is being sent out by the Standard Underground Cable Company, of Pittsburgh, Pa., as a reminder that it is prepared to promptly fill all orders, large or small, for bare copper, iron or steel wire, weather-proof annunciator, office or magnet wire, galvanized steel strands, rubber-covered wire or cables, lead-covered cables for underground or aerial use, armored submarine cables, cable hangers, terminal or junction boxes and underground conduits. These various products are the results of many careful and costly experiments and tests by the corps of skilled experts constantly in the employ of the company, and the sixteen years of experience that the Standard Underground Cable Company has had in this line guarantees its competency to satisfactorily fulfil all contracts intrusted to its care. The little rule and wire gage is made in three sections, which fold upon each other, and it will be found very convenient for frequent use.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has recently booked many orders from England for street railway motors. There are 262 motors and eight generators to be turned out with all possible speed. An abstract of the contracts on hand is as follows: For the Hull Tramway Company, ninety-two electric ralway motors to equip forty-five cars and one track sweeper; for the Halifax Tramway Corporation, twelve motors to equip six cars; for the Bradford Tramway Corporation, forty-eight motors to equip twenty-four cars; for the municipality of Norwich, which has control of the tramways in that city, eighty motors to equip forty electric cars, and four electric generators to be installed in the power house of the Norwich Tramway Corporation, to generate the current for the operation of the line; for Coventry, twenty motors have been ordered to equip ten cars, and the order has been augmented by a call for two power generators. Plymouth has an order for ten motors and two power generators for operation of local electric railways.

THE WARREN ELECTRIC MANUFACTURING COMPANY, of Sandusky, Ohio, has appointed J. Holt Gates & Company, 1426 and 1427 Marquette building, Chicago, general agents for its apparatus in the Western territory surrounding Chicago. The Warren Electric Manufacturing Company has recently placed, through J. Holt Gates & Company, a 15,000-light alternating-current plant for the great new power and light plant of Armour & Company, at their extensive works at the Union Stock Yards, Chicago. This plant will consist of one machine of 7000 16-c.p. light capacity, at 1100 volts and 7200 alternations; also two 3600-light machines, at 1100 volts and 7200 alternations. These alternators are of the inductor type, and will be operated by rope drive from Corliss engines of 2000 h.p. and 1100 h.p. each, to which engines will also be attached Walker direct-connected power generators. It is stated that the Warren alternators were selected on account of their close regulation, high efficiency, low temperature and ability to stand "grief." The Warren Electric Company is now prepared to build 10,000-light machines, both single and two-phase, in its new factory, and has about sixty machines on order at the present time. Its new plant at Sandusky, Ohio, is modern and up to date.

RECENT DESCRIPTIVE MATTER CONCERNING MECHANICAL DRAFT.—The B. F. Sturtevant Company, of Boston, Mass., has brought out within the past few weeks a number of new pamphlets and circulars setting forth the advantages of mechanical draft for factories, power stations, etc. One of these circulars, entitled "Draft Without a Chimney," explains why the B. F. Sturtevant Company has taken down its tall chimney and substituted mechanical draft, and states that an annual fuel saving of nearly $1,000 has been secured thereby. The company has also found it necessary to issue a second edition of the lecture on mechanical draft for steam boilers, delivered at the Cornell University by Walter B. Snow, of the engineering staff of the B. F. Sturtevant Company, in order to meet the demand for information on this important subject. In addition to its mechanical draft system the B. F. Sturtevant Company manufactures generators and motors and direct-connected units for all classes of service. Its catalogue, Bulletin G, illustrates a unique generating set, in which both the engine and generator are entirely inclosed, although practically accessible through suitable doors. Such a device is of manifest utility wherever the atmosphere is laden with dust. All these circulars will be mailed on request.

BENT GLASS.—It is a well-known fact that bent glass adds to the attractiveness of any building or store front, in fact, a single pane gives extra tone to the whole structure. To those contemplating building or making alterations, it is important to know that common double thick glass can be bent to any part of a circle not exceeding half circle. Polished plate can also be bent in the same manner. The difference in appearance between the two lights after bending is hardly perceptible, in fact, when set in a building it would require an expert to detect any difference at all; however, there is quite a difference in the cost; bent double thick glass is only about one-fifth of the cost of bent plate glass, which is considerable of a saving in the construction of a building. The curving or bending of double thick glass takes away the waviness, gives a polish to the glass, and adds to its strength

and resistance to high winds and severe storms. This was clearly demonstrated in the city of St. Louis by the tornado that visited that city May 27, 1896. The largest manufacturer of bent glass exclusively in the United States is the Oriel Glass Company, of St. Louis, Mo. This company manufactures all kinds of bent glass for buildings, show cases, fancy furniture, etc., the product being all of superior make and finish, and shipped in large quantities, not only to all points in the United States, but also to Canada and Mexico.

THE WESTERN ELECTRICAL SUPPLY COMPANY, of St. Louis, Mo., has had a successful career of eight years in the general electrical supply business, and has experienced a phenomenal growth in its various departments. This is especially noticeable in the street railway department, which has developed through the company's tireless efforts to supply what the trade demand, into a very satisfactory and gratifying business. This company carries in its St. Louis stock a very large and complete assortment of all supplies pertaining to street railway business, and it has succeeded in establishing an excellent reputation for making shipments with promptness and despatch, and its growth is undoubtedly due to a large extent to its prompt delivery of goods, as street railway companies fully appreciate the advantages of being able to secure the majority of their goods from stock, thus obviating the necessity of tedious and often exasperating delays on the part of manufacturers. It seems more than likely that the Western Electrical Supply Company, situated as it is, in the Southwest, which enables it to reach a large and spacious territory, will continue to increase its large business in this line, and receive the hearty support of street railway companies. This company represents some of the largest and best-known manufacturers of street railway supplies in the country, and is therefore able to furnish many specialties in this line which a street railway may require. It has recently issued a very complete catalogue, confined strictly to street railway supplies, and which may be had for the asking. This book was described in the January issue of the STREET RAILWAY JOURNAL, and will be found of value to all street railway companies.

New Publications

Powers of Municipalities. By Allen Ripley Foote. Paper. 79 pages. Published by the Robert Clarke Company, of Cincinnati, Ohio.

This is a discussion of the report on the municipal problem of the special committee of the National Municipal League.

The Customs Tariff of Japan, in Effect January 1, 1899. Paper. Published by Japan-American Commercial and Industrial Association, Times Building, New York.

In this pamphlet are given the ad valorem and specific duties contained in the new tariff law published March 29, 1897.

Massachusetts Institute of Technology Courses in Electrical Engineering and Physics. Paper. 65 pages. Published by the Institute.

This contains a full description of the laboratories, etc., of these courses, which have come to be the most popular in the Institute.

American Trade Index. Flexible linen. 276 pages. Published by the Association at its office in Philadelphia.

This is a descriptive and classified membership directory of the National Association of Manufacturers of the United States, arranged for the convenience of various buyers, and is a valuable book for its purposes.

Mechanical Features of Electrical Traction. By Philip Dawson, A. M., I. M. E. Paper. 16mo. 123 pp. 14 plates. Published by authority of the Council Institute Mechanical Engineers, London.

This is an excerpt from the minutes of recent proceedings of the Institute of Mechanical Engineers, containing a paper read by Mr. Dawson before the Institute and the discussion thereon. Many of the plates and tables are of much value.

Third Rail Electric Traction. By Charles Henry Davis and W. G. Howells. 84 pages. Paper. Illustrated. Reprinted from the "Municipal and Railway Record," New York.

In this article, which has been printed in pamphlet form, the authors briefly review the subject of surface contact and underground electric railway conduit systems. The greater part of the article is devoted to illustrations of the chief systems which have been proposed or are in use, and the authors deserve great credit for having collected and put in permanent form so much interesting data of this character.

The Technology Review. A Quarterly Magazine published at 71 Newbury Street, Boston, by the Association of Class Secretaries of the Massachusetts Institute of Technology. Price $1 per annum, 35 cents per copy. Volume I. No. 1. 143 pages.

This is a new quarterly of interest chiefly to the students and alumni of the Massachusetts Institute of Technology, but containing articles of general interest to those working in scientific fields. Its first number contains an article on the "Function of a Laboratory," by Silas W. Holman, together with reprints and fac simile of early institute documents and letters descriptive of the new buildings, and general institute news.

Up-to-Date Air Brake Catechism. By R. H. Blackall, Air Brake Instructor and Inspector on the D. & H. R. R. 240 pages. Illustrated. Price, $1.50. Published by Norman W. Henley & Co., 132 Nassau Street, New York City.

The increased use of heavy double truck electric cars has made the subject of air brakes an extremely interesting one, so that the book mentioned contains much of value to the street railway engineer. It is written in the popular catechism style and contains nearly a thousand questions with their answers. It is fully illustrated, and the engravings include two large folding plates of the Westinghouse quick-action automatic air brake and the 9½-in. improved air brake.

The Story of the Railroad. By Cy Warman. Cloth. 12mo. 280 pages. Illustrated. Price, $1.50. Published by D. Appleton & Company, New York.

This book pictures the building of the earlier transcontinental lines across the true West. It tells the story of the engineer who found the way and who was the pioneer of permanent civilization among the Indians and the buffalo of the plains and in the mountains. Historically, the book is valuable, because it gives a comprehensive sketch of a great subject in a brief compass, and, furthermore, the strange and picturesque phases of life which are depicted are full of immediate interest. An actual war, now forgotten, for the possession of a cañon in Colorado, is vividly described by the author, who has shared in the work of the railroad men, and who made a special journey through the West to gather fresh material for this valuable and entertaining book.

Matter, Energy, Force and Work. A Plain Presentation of Fundamental Physical Concepts and of the Vortex-atom and Other Theories. By Silas W. Holman, Professor of Physics (emeritus) Massachusetts Institute of Technology. 257 pages. Price, $2.50. Published by the Macmillan Company, New York.

To all who know Prof. Holman's keen, clear and intelligent brain, and his ability in putting before a student or reader an accurate conception of fundamental physical facts and theories, this book will instantly appeal as a valuable addition to their engineering library. Chapter I. deals with the established fundamental facts about substance and matter, motion energy in its various forms, force work and measurements. Part II. deals with speculations on matter and energy, including treatises on the function of theory and hypothesis, the kinetic theory of gases, Le-Sage's theory of gravitation, the vortex-atom theory, and the nature of energy and matter.

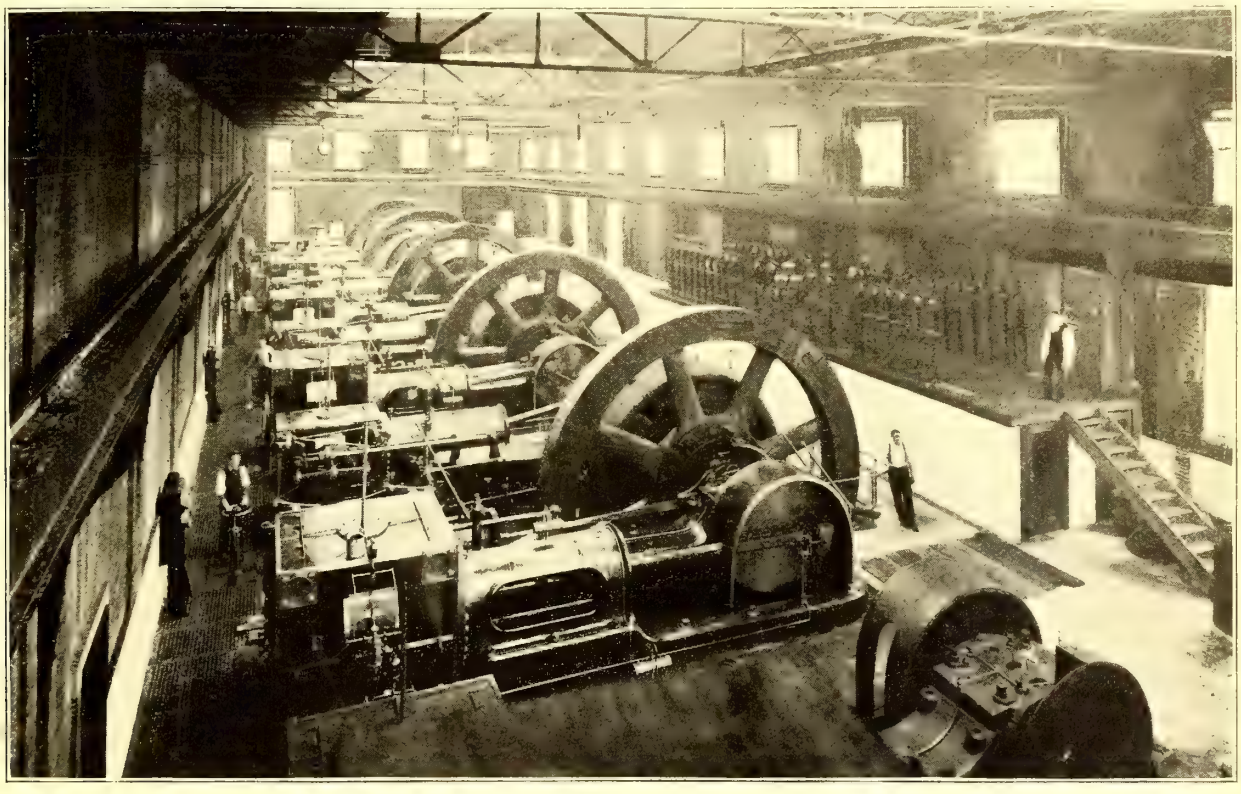
Street Railway Journal

VOL. XV. NEW YORK AND CHICAGO, MARCH, 1899. No. 3.

NEW POWER STATION, REPAIR SHOPS AND CAR HOUSES OF THE CONSOLIDATED TRACTION COMPANY OF PITTSBURGH

There are few street railway companies in the country, whose systems were equipped several years ago, that have so thoroughly changed over their methods and appliances to adapt them to the requirements of the hour, as the company named in the title of this article. The changes made, constitute, in some cases, radical innovations from standard practice, not only in the electrical equipment, but also in the mechanical and architectural departments, so that a study of the system is a particularly interesting one. The chief engineer, who is also manager of the system, originated all the plans and details, and is to be congratulated on the satisfactory results that have been reached, and commended for the original and novel manner in which the peculiar local problems have been met and mastered.



When the various cable and electric lines in the city of Pittsburg were consolidated, the new company found itself in possession of seven power houses; four of these, namely, Washington Street, Oakland, Wylie Avenue and Thirty-fourth Street, were cable power houses of the usual type; the other three, Forty-seventh Street, Ben Venue and Allegheny Traction, were electric power houses.

Before, and during the reconstruction of the system, these electric power houses were, of course, kept in operation, but there arose the problem as to what arrangements must be made for supplying power to the much larger system when completed. An examination of the list and map on the following page will show the situation as it stood.

It will be seen that none of these plants were well situated with regard to coal and water supply, the most important factors in the location of a large power house. The cable power houses were necessarily located on the streets along which the cables were operated, and therefore little regard was paid to coal and water supply. These plants stood on valuable ground, the cost of hauling coal by wagon was large, and lack of water rendered the use of condensing engines impractical.

The electric power houses were somewhat better off in regard to coal supply, but Forty-seventh Street and Allegheny Traction were too far from centre of system, while Ben Venue had no suitable water supply, and only one source of coal supply. It became evident, therefore, that one or more new power stations were demanded in localities not too far removed from centre of system, and where coal and water were easily and surely obtainable.

In deciding between one large plant and two or more smaller ones, Pittsburgh's marked geographical peculiarities largely influenced the result. The street railways converged in the crowded business portion down town, and again at East Liberty, after traversing a district of heavy grades. This brought the centre of the system in the midst

VIEW IN CENTRAL POWER STATION—CONSOLIDATED TRACTION COMPANY, PITTSBURGH

of the hills, as shown on the map, at a considerable distance from available coal and water supply, hence it was impracticable to put power house in this part of the system. Railroads are compelled to follow the Monongahela and

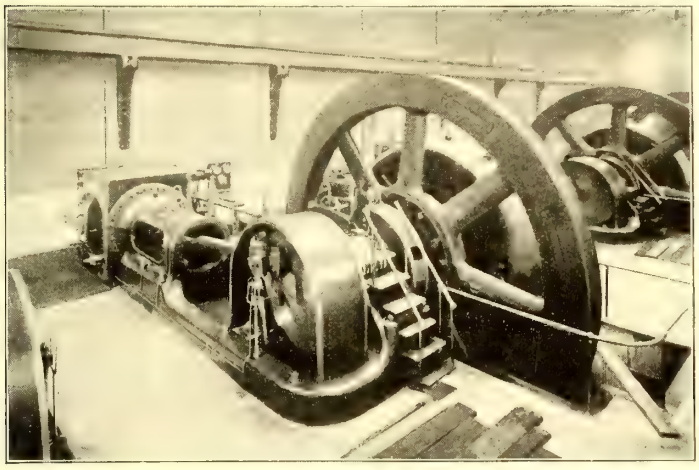
Allegheny valleys, so that both coal and water are readily obtainable along the banks of these rivers. A location on the Allegheny River, on the other hand, offered advantages of far better water, with equally good coal facilities, nearest to the centre of the system, and of less difficulty in obtaining land.

With so little choice in location, the advantages of a single power house, rather than two or three in different parts of the city, seemed to the managers of the company evident. Danger of fire and of accident to a single plant can be eliminated by proper construction, while much of the initial cost and operating expense of the plant is independent of the size, and therefore, as great for each of the smaller plants as for the large one. To illustrate the economy of a single power station over the several original ones, it might be stated that the operating expenses of five of the old plants as compared with the new one are about two and one-quarter times as great.

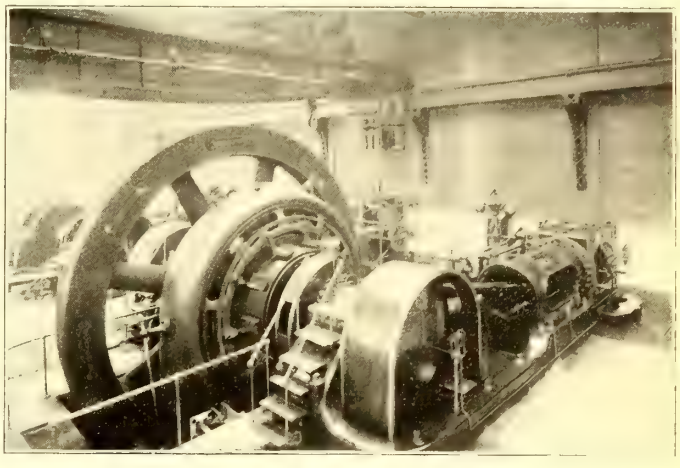
The new station is larger than the combined capacity of the old stations considered, yet runs for less than one-half the daily operating expense. The value of the real estate of the separate plants is sufficient to cover the cost of construction of the new station.

The location finally obtained was at Twentieth Street, between Railroad Street and the Allegheny River; the property being 177 ft. deep, and 360 ft. to harbor line; the length of the building was limited to 265 ft. by a private right of way. Coal can be secured from either the B. & O. system, the Pennsylvania Railway, or from the river, while an unlimited supply of fairly good water is close at hand.

The station is designed for a 12,500 nominal h.p. equipment, which will consist of eight units, six of which are at present installed. Each unit comprises a 1560 h.p. engine of the cross compound condensing type, with "Corliss" valve gear direct coupled to a 1000 kw. generator. The cylinder dimensions are 30 ins. and 54 ins. x 48 ins. The rating given above is based upon a cut-off in the high pressure cylinder of 23 per cent and a terminal pressure in the low pressure cylinder of 6 lbs. above absolute vacuum, and running at 80 r.p.m., but with a higher percentage of cut-off the machines are easily capable of developing 2500 h.p. each. The steam and exhaust valve are operated by separ-



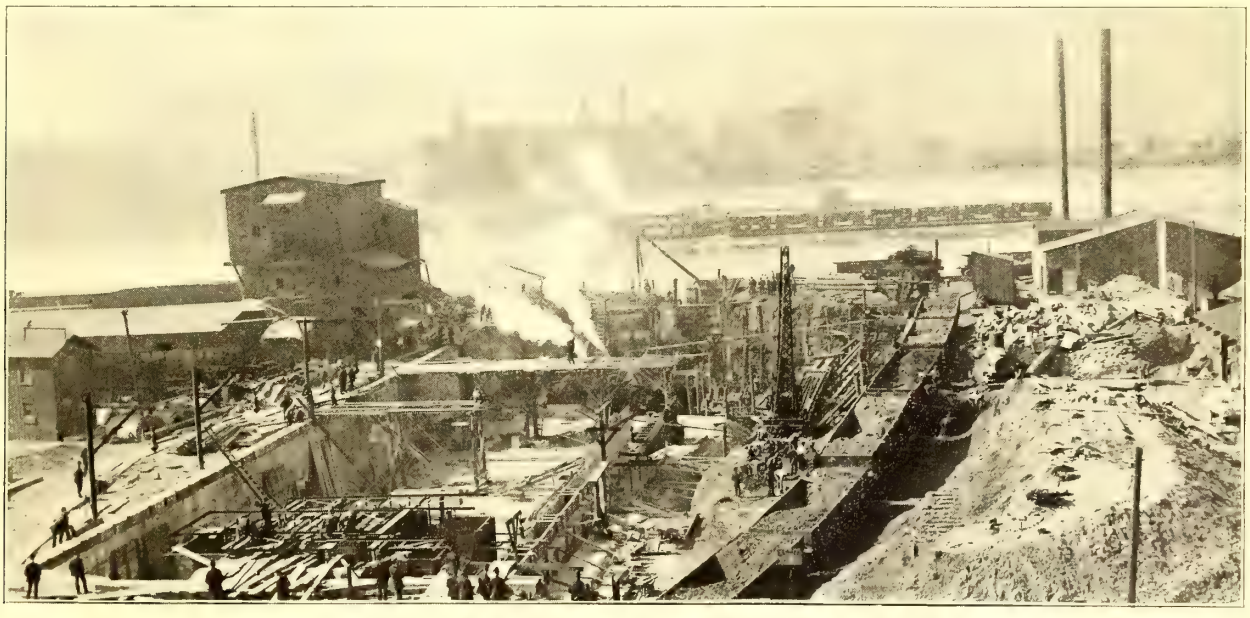
ate eccentrics, and the governing mechanism controls the steam in both cylinders. Reheating receivers are placed between the high and low pressure cylinders, being located beneath the floor of the engine room, and the steam and exhaust pipes are attached to the under side of the cylinders. In this way there are no steam pipes visible in the engine room, and there is nothing to interfere with the operation of the traveling crane which is provided for handling all heavy parts.



In the design of the engines, horizontal engines were chosen, because it was found that the type selected could more readily accessible for attendance and repairs, and less be put in even less floor space than vertical engines, are expensive.

At first sight, there is nothing very striking in the design of these engines, except that the outlines are graceful

for so large a mass of metal, but there is a combination of simple factors which renders them exceptionally efficient. The bed plate is of the Tangye type, the plate and pillow block being cast in one piece, while the cylinders are overhanging and supported on a rest plate, which is adjusted for the support of the cylinder, after expansion has taken



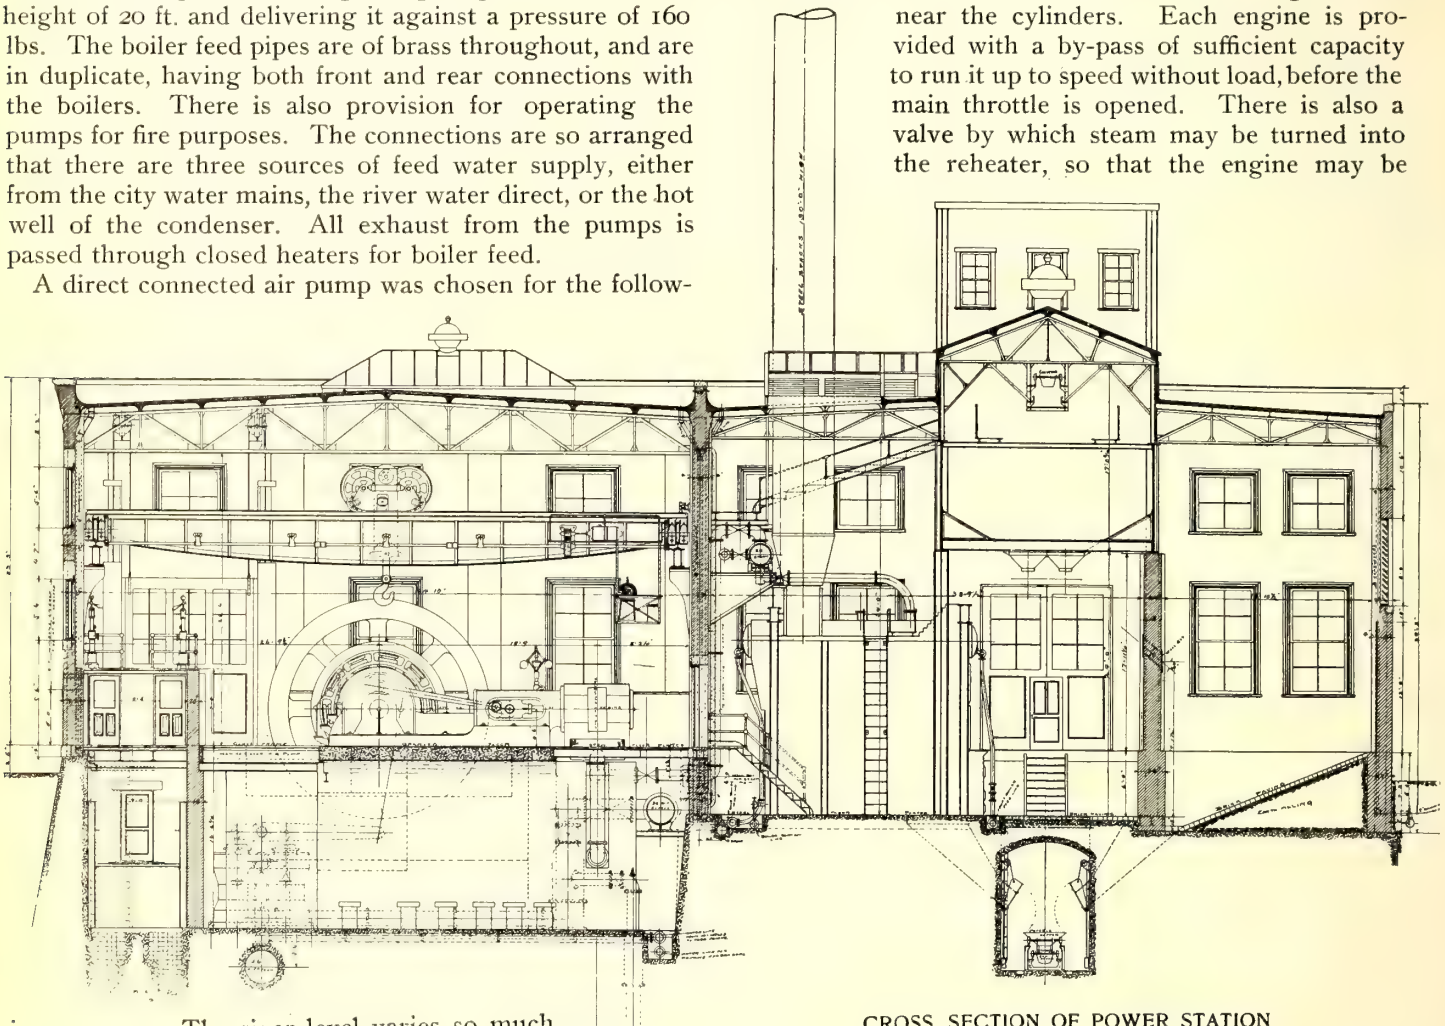
LOW PRESSURE SIDE OF ENGINE

HIGH PRESSURE SIDE OF ENGINE

place from the action of the steam. Each pair of cylinders are steam jacketed, the barrel and jacket being cast together. All the journal bearings and the connections for the valve gear have screw and wedge adjustment. The journal bearings have the adjustment on the sides, but the wedges are accessible through the top cap. The main bearings are 20 ins. in diameter, and 40 ins. long; this may seem very wide for a 44,000-lb. armature and 110,000-lb. fly wheel, but the engineers prefer to distribute the wear over a large surface, believing that there is much less danger of the bearings wearing to a dangerous degree. The fly wheels are each 20 ft. in diameter and weigh 110,000 lbs.

CONSTRUCTING FOUNDATION FOR STATION

An automatic oiling system is used, and the caps of the main bearings have each three oil cavities protected by brass strainers. From the different bearings the oil is led to filters in the basement, from which it is pumped to elevated tanks, and descends by gravity to the different bearings. The air pumps of the jet condensers are of the double acting type, and are operated by a rod from the extension of the crank pin of the low pressure side. The condensers and auxiliary steam equipments are located in the basement of the structure, or rather chambers provided for them in the engine foundations, which are built up of concrete to the height of 17 ft. above the foundation floor. The condensing water is lifted by pumps from an intake pipe 40 ft. below engine room floor, and which extends under the bed of the river. The engines were built by the Pennsylvania Iron Works Company from specifications furnished by the engineers of the Consolidated Traction Company.



The boiler equipment consists of six batteries of forged steel type sectional water tube boilers of special design made by the Babcock & Wilcox Company. Two boilers constitute a battery, and each battery is rated at 750 h.p. In order to economize floor space, these boilers are shorter and higher than the usual type. Each is made up with three 36-in. drums, 20 ft. long, and 18 sections of tubes, each 15 ft. long, giving about 4000 sq. ft. of heating surface. They are designed for a pressure of 200 lbs., and were tested under hydraulic pressure to 300 lbs. The fire boxes are equipped with the Hawley down draft furnaces, having a grate surface of 66 sq. ft. The furnaces are guaranteed to show 10 per cent greater efficiency than the ordinary flat grate and to be able to burn 40 lbs. of coal per square foot

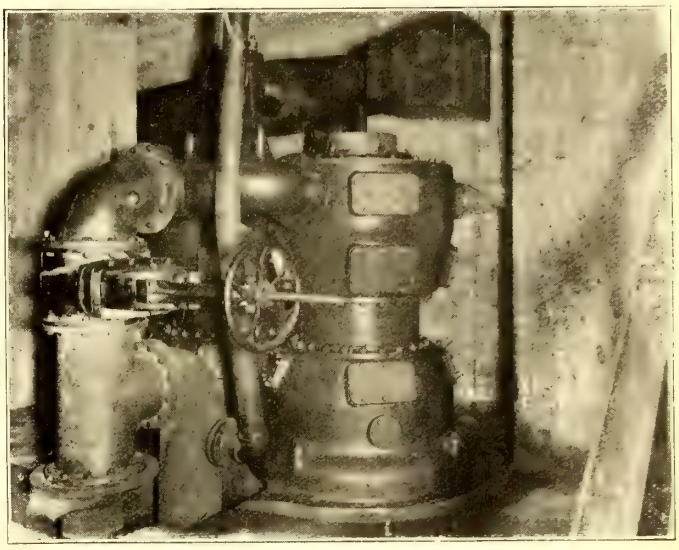
of grate per hour, and to reduce the smoke by 92 per cent. The boilers with the Hawley furnaces are guaranteed to develop 75 per cent efficiency with less than 1 per cent of moisture at full load, or 1½ per cent at 50 per cent above rating. In tests which have been made the above guarantees have been attained. There are six unlined iron smoke stacks, one for each battery. Each stack is 66 ins. in diameter, and rises 147 ft. above the grate bars, giving a draft of 1 in. to 1½ ins. of water under ordinary conditions. The breechings and stacks are carried on special supports entirely independent of the brick boiler setting.

The feed pumps are three in number, of the Worthington duplex direct acting type, with outside packed plungers, and are capable of lifting 240 gals. per minute to the height of 20 ft. and delivering it against a pressure of 160 lbs. The boiler feed pipes are of brass throughout, and are in duplicate, having both front and rear connections with the boilers. There is also provision for operating the pumps for fire purposes. The connections are so arranged that there are three sources of feed water supply, either from the city water mains, the river water direct, or the hot well of the condenser. All exhaust from the pumps is passed through closed heaters for boiler feed.

A direct connected air pump was chosen for the following reasons: The river level varies so much that any style of pump would have to be designed to do more than is ordinarily required of it, hence the pump will rarely be running at full load, and will therefore be less economical than in the case of more uniform water supply; the effect on the economy, it was thought, would be less, however, in the case of a direct connected air pump where it practically forms part of the friction load of a large compound condensing engine, than in the case of either a single separate pump or a number of smaller pumps designed for economy. Moreover, separately driven pumps, it was thought, would be more expensive (if equal workmanship is obtained) because the cost of steam cylinders and valve gearing is added to that of the pump itself; starting with a direct connected air pump is very much easier, and practically no attendance during operation is required. The main disadvantage, of course, is that the engine must be run non-condensing in case of break down of its own pump.

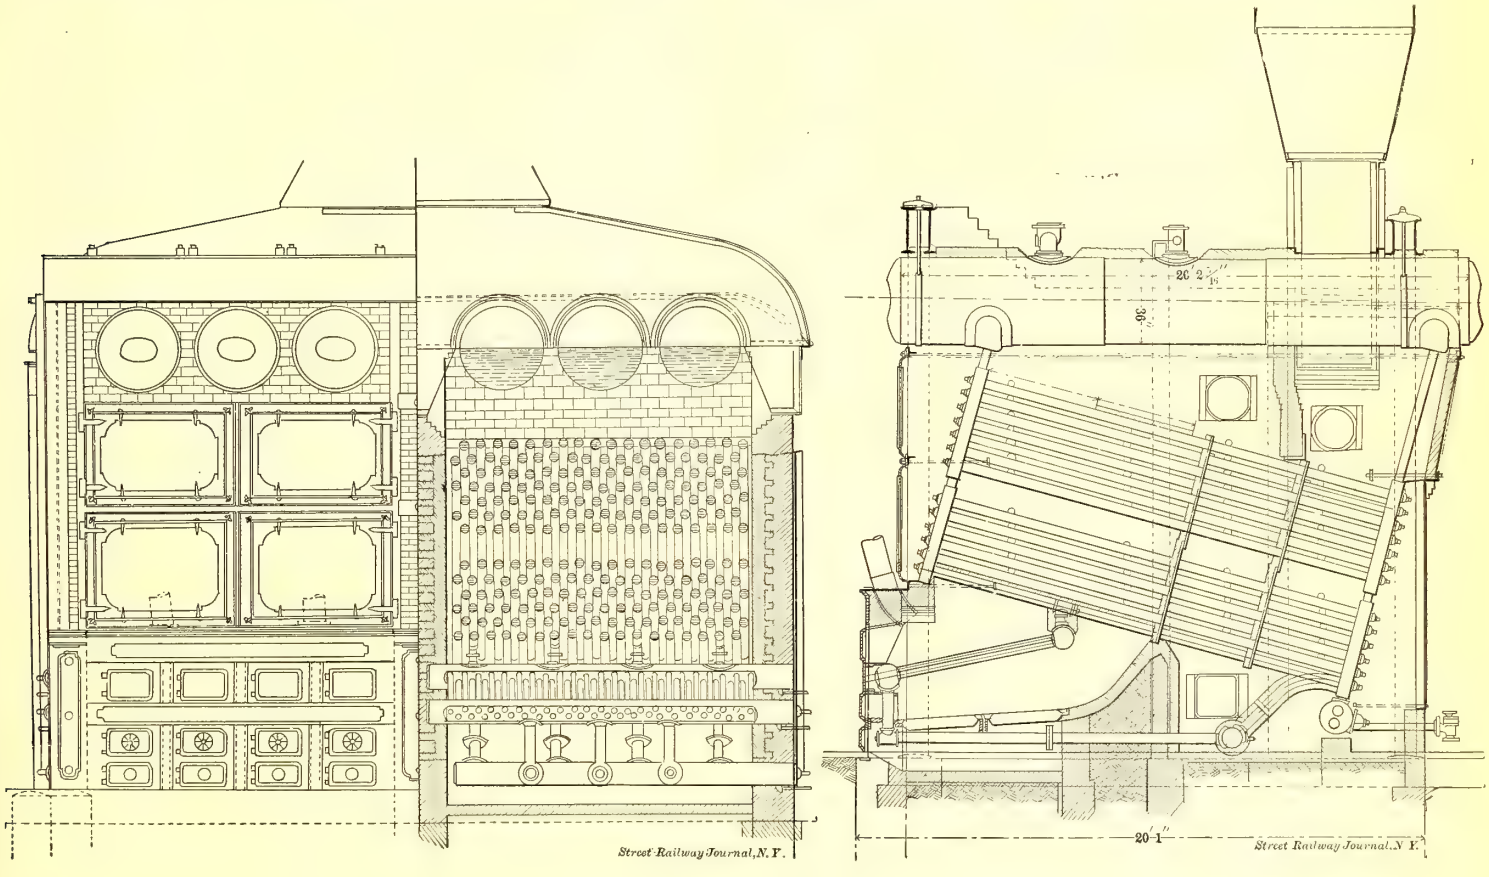
The steam piping is of cast steel throughout, and each boiler is connected to a 20-in. steam main, which is located along the top of the boiler room above the back end of the boilers, and this main is provided with two copper expansion loops. The main is divided by valves between each battery of boilers, and the steam enters it from the boilers through pipes having a long radius bend, which are tapped into the under side of the main. The pipes leading to the engines lead out from the top of the main and bend down along the wall and out under the floor of the engine room. The valves are of the Chapman manufacture, and are operated from a gallery that runs along the entire side of the boiler room, back of the steam main. The throttle valves and by-pass valves are operated from wheels on four valve stands on the floor of the engine room near the cylinders. Each engine is provided with a by-pass of sufficient capacity to run it up to speed without load, before the main throttle is opened. There is also a valve by which steam may be turned into the reheater, so that the engine may be started by the low pressure cylinder, should the high pressure side be on the center. The exhaust steam pipes terminate at each end of the building above the roof in two Marlin exhaust steam heads. These are each 15 ft. high and 12 ft. 6 ins. in diameter at the top, being among the largest exhaust heads so far erected in this country.

CROSS SECTION OF POWER STATION



Adjoining the boiler room, and separated by a wall running the whole length, is a storage bin for coal, in the lower part of the separating wall are coal chutes which eventually will be used as ash pits whenever the station is enlarged, the structure being so designed that the coal space can be utilized for a boiler room whenever the capacity of the station is to be increased. The main coal bunker, however, is an elevated steel structure made of plate girders 10 ft. deep and extends the entire length of the boiler room. This bunker has a capacity of 6 tons per running foot, or a total capacity of 1632 tons. A Mead coal conveyor with an automatic weighing bucket with a capacity for handling 40 tons per hour is used. This con-

veyor is driven by an electric motor, and takes about 15 h.p. to operate it. The coal is received by rail at the river end of the boiler room, and, after being weighed, is elevated about 50 ft. and passed to the coal bunker, being dumped anywhere desired. Afterward the conveyor passes into tunnel beneath the boiler room and is utilized for removing ashes.



The exterior of the building is of Pompeiian brick with Cleveland sandstone trimmings; the interior of the engine room is Pompeiian brick with enameled brick wainscotting, having a slate cap. The floor is of Mosaic known as "granito," with slate border. The roof is supported on steel riveted girders of the Warren type, having one inclined top chord. The specifications for the framework called for open hearth steel having a tensile strength of from 60,000 to 65,000 lbs. The roof is cinder concrete with iron stiffing bars, having felt and crushed slag imbedded in pitch on the upper surface. Large ventilating and lighting areas with wire screen guards as a protection against falling glass, are also provided.

In the design of the foundations, it was necessary to avoid the possibility of a flood stopping the plant, hence the engine room floor level was fixed 1 ft. above the highest recorded level of the river (a stage of 33 ft. 8 ins. in 1884), normal pool level being stage of 6 ft. On the other hand, the intake pipe must at all times be completely covered with water, thus requiring the top of the pipe to be below stage minus 1; the pipe had to be kept below this level underneath the engines, to keep the vacuum from being lost in times of low water, hence there was required an excavation over 300 ft. in length and over 40 ft. deep from the surface, or 13 ft. below normal river level. This pipe was surrounded with concrete to make it permanent, and to secure good foundation for the engines above. Concrete was chosen because of the ease of handling it in difficult places, such as under caving banks, without removing bracing in water, etc.

The ground dimensions of the entire structure are 272 ft. x 115 ft., while the engine room is 55 ft. wide and the boiler room 60 ft., including the coal storage bin above described. An electric traveling crane of 90,000 lbs. capacity spans the engine room and serves for the quick handling of any piece of machinery or piping. To provide for the lifting of the condensers, areas are left in the engine room floor. These spaces are covered with iron grating that can be readily removed. Similar provision is made in the floor between the back wall and engine cylinders for reaching the steam piping and the reheaters. The foundations of the building contain 20,000 cubic yards of concrete, the side walls being in some places 7 ft. thick. The whole foundation is built as a unit, and has a bed of river gravel upon

DOUBLE ACTING DIRECT DRIVEN AIR PUMP WITH BALANCE LEVER

SIDE ELEVATION AND SECTION OF BOILERS

which it rests. In the process of building, a concrete mixer, referred to more particularly later, was used. The material, or rather the sand and gravel for the foundation was obtained from the river near by, and the material was hauled from the boats up an incline and delivered to an automatic measuring cylinder, which delivered the material, sand, gravel and cement in proper proportion to the mixer.

STORAGE BATTERY STATIONS

There are three storage battery stations, each located about 3 miles from the power station, and so distributed that they serve to balance the load in a very satisfactory manner. The first of the battery stations was installed in 1897, and the second soon after. The equipment of these two stations consists of 248 cells each, having a capacity of 500 amps. The third, the one recently installed, has a capacity of 1000 amps. For this station a new building has been recently erected on one of the business streets in East Liberty. In addition to its use as a battery station, the first floor will serve as a receiving house, as the batteries occupy the basement. The rear portion of this building will accommodate an emergency wagon of the automobile type, for which storage batteries will furnish the power. The rear of the second floor is finished up with sleeping and toilet rooms for the accommodation of the emergency force, and is fitted with a pole down which the men slide when a call comes, as in fire department stations.

SWITCH ROOM

The generators are of 1000 kw. capacity each, and as mentioned in the Street Railway Journal for February, 1898, are designed for operating the line by the three-wire system. The switchboard and all the connections are also thus wired, but the road is being operated by the single wire system at present. The term switchboard in connection with this plant is a misnomer, for there is no switchboard in the ordinary sense of the term, but in its place there is a four-deck vault or room, 48 ft. x 9 ft., one side of which is formed by the foundation and brick wall, while the remaining walls are of brick. The floor is of slate supported on steel girders, making the chamber fireproof. The cables, which are of 1,000,000 c.m. capacity, lead out from each machine, through tile ducts located in the floor of the basement. These communicate with the lower gallery of the switchboard room, and from this the nine cables from each machine lead up into the second gallery, being held by iron supports having mica bushing, so that there none of the weight is supported by the circuit breakers. The circuit breakers are arranged in rows on each side of the second gallery, while the double throw switches are supported from the ceiling, and all are arranged to be operated by pneumatic appliances from stands on the upper deck. The circuit breakers are thrown in by single acting air cylinders, while there is also a small cylinder for tripping the circuit break when necessary. The switches are

STORAGE BATTERY

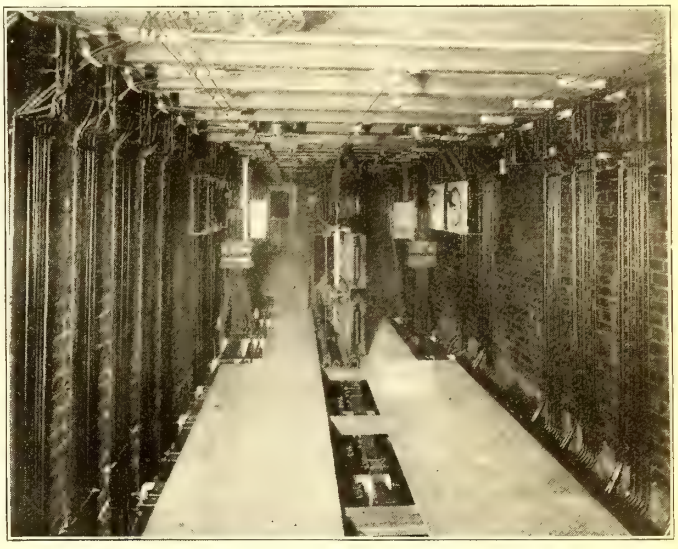
controlled by a double acting cylinder. There are thirty-two 1,000,000 c.m. cables which form the return circuit, and these are connected to a vertical bus bar located in the middle of the second chamber, this, in turn, is connected to the neutral bars above. The bus bars proper are placed in a horizontal position and are located between two sets of I beams, the lower of which forms the support for switches in the room below, and the upper set supports the slate walks of the third chamber, being in plain sight and easily accessible. The bus bars, both for the positive, negative and neutral limbs, are each made up of fifty copper strips of 3 ins. x ⅛-in. section, each being of sufficient capacity for the distribution of the current of all of the 1000 kw. generators, when it becomes necessary to operate by the three-wire system.

On the walls of the third chamber are placed two watt meters, rheostat face plates, air pipes, ammeter leaves, etc. In the center of this chamber are the rheostats, which are

protected by a perforated metal cover. The controlling stands are located on the upper deck, which is really a platform overlooking the engine room. From this platform all the current controlling appliances are operated. These stands are numbered, and there is one for each feeder and one for each generator. These stands are arranged in two rows, with one stand in the middle, on which is placed the air pressure gage, alarm bell for low air pressure, and air valves for lighting switch and circuit breaker of the station lighting circuit. This latter is so connected to the leads of any of the generators, that should all the generator circuit breakers go out, the station would not be left in darkness. On the top of each controlling stand is a red tell-tale lamp, which lights automatically when the corresponding circuit breaker is thrown out. Below this is an ammeter illuminated by a shaded lamp, while near the middle of each stand are two handles which operate the air valves for circuit breakers and switches. These handles are so interlocked that the switch cannot be operated when the circuit breaker is in, nor can the circuit breaker be closed when the switch is in, so that it is impossible for the attendant to make a mistake. The generator stands have, in addition to the above, a small hand wheel for operating the rheostats, and a receptacle for plugs for connecting the volt meters to the different generators. At the middle of each row of stands is a revolving stand, on one of which are three volt meters, and on the other three ammeters, which can be turned so that they may be read by the attendant at any point on the platform. One volt meter is connected to the plug switch, and the other two give the voltage of the positive and negative bus bars, respectively, while the three ammeters give the current of the positive, negative and neutral bars. The instrument for the negative bar is double reading, and shows which side of the three-wire system has most load.

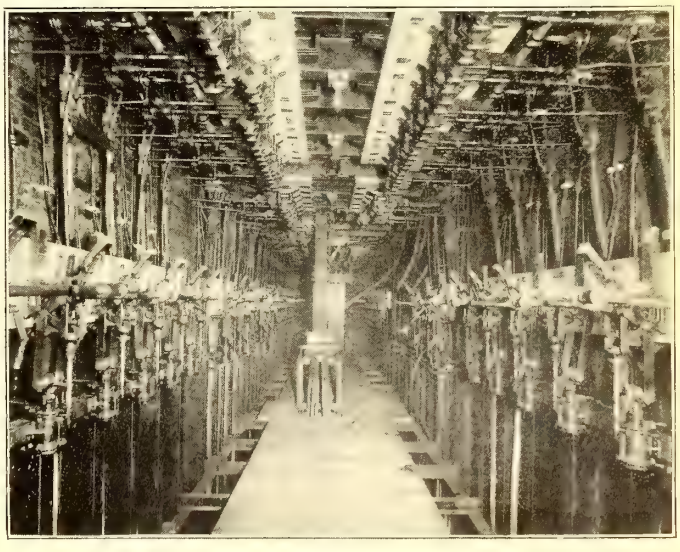
From the switchboard the lead covered cables are carried through a subway to a brick tunnel, which leads off through the foundations of the building in the direction of Penn Avenue, and which extend a distance of nearly 600 ft. The interior dimensions of this tunnel are 5 ft. x 7 ft., or sufficient to provide for the ultimate capacity of 40,000,000 c.m. of feeder cable, beside room for the free passage of the employees. In the construction of this tunnel, there was imbedded in the concrete foundation in two rows extending the whole length of the tunnel thirty-two girder rail conductors, the rails being 63 lbs. section per yard. The ends of these rails are double bonded, and to these the return feeders are attached. At Penn and Liberty Avenues the cables are brought up through large distributing poles, from which they lead off in eight directions, being supported from the trolley poles.

The diagram opposite shows graphically the calculation to determine the most economical size of feeders to employ, consideration on the one hand being taken of the loss of power through resistance, and, on the other, of the interest on the investment.



CONSTRUCTION OF PLANT

Excavation for the power station was begun Sept. 1, 1897, the material being shoveled directly into cars on the siding leading on to the property. After the excavation deepened, and the grade became so heavy that this method became impractical, two machines were used, one a bucket conveyor, the other a traveling hoist. The total excavation amounted to about 35,000 cu. ft.



As the walls and the foundations proper of the engines, as well as of the building, were of concrete, hand mixing was out of the question. A machine mixer was therefore erected. It was about 20 ft. x 16 ft. and 32 ft. high, and although largely experimental, did good service, turning out on some days over 500 cu. yds. per day of twenty hours, when that amount could be used, and making a total of about 20,000 cu. yds. The following table gives

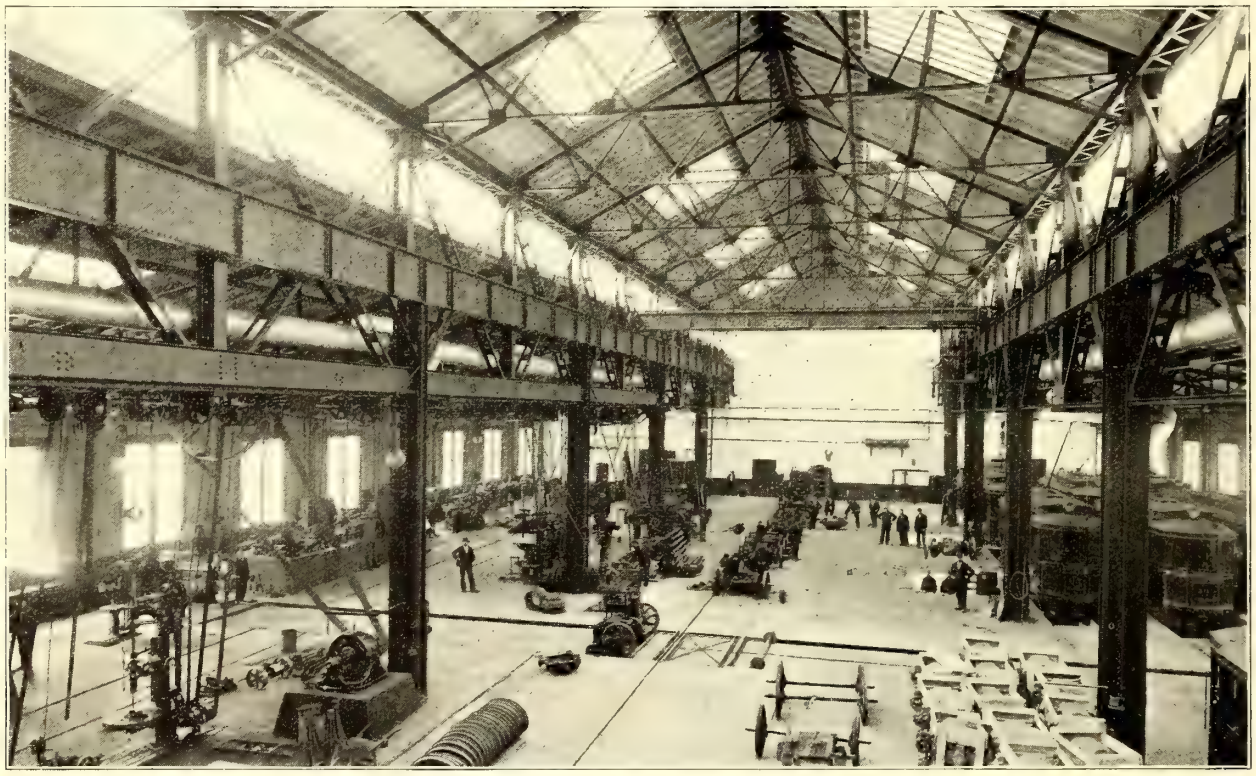
CONTROLLING STANDS ON TOP GALLERY

UPPER GALLERY, SHOWING BUS BARS AND RHEOSTATS

LOWER SWITCH GALLERY, SHOWING CIRCUIT BREAKERS ON SIDES AND SWITCHES OVERHEAD

the cost of mixing concrete by the mixer, as estimated from actual experience during the past year:

Cost of materials	1-4-10	1-3-8	1-2-5
American Portland cement, @ $2.05 per bbl.	$1.37	$1.69	$2.66
Sand, @ 2½ cents per bu.	0.30	0.29	0.29
Gravel, @ 2 cents per bu.	0.38	0.38	0.37
	$2.05	$2.36	$3.32



Cost of delivery to Mixer of materials	$0.07
Cost of measuring and mixing	0.05
Cost of delivery 150 ft. and return by wheelbarrow gang	0.23
Cost of tamping	0.18
Total cost of labor	$0.53

(The above represents the average of an ordinary day's run, but does not include share of cost or depreciation of mixer plant.)

An American Portland cement was used throughout, mixed with sand and gravel in proportions varying from 1-3-8 to 1-2-5; no broken stone was used as actual tests on concrete blocks showed that an equally strong concrete could be secured at lower cost by the use of gravel alone.

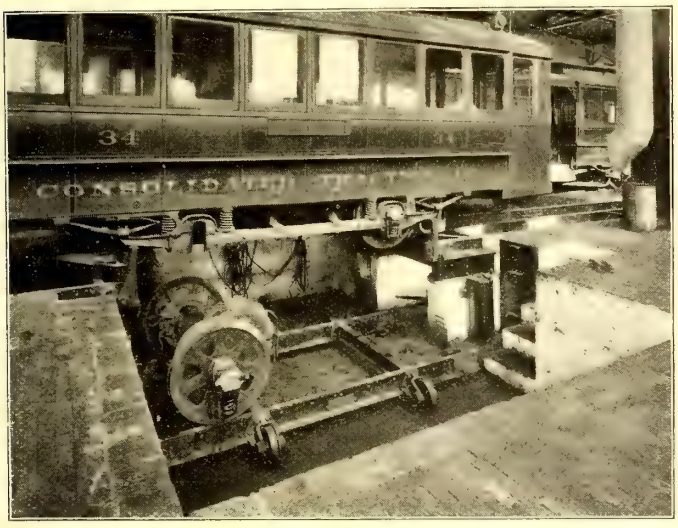
brick floor cement grouted. The second building in line is the repair shop proper, is 135 ft. x 576 ft. and is divided into the iron tool department, wood shop and erecting department and paint shop. The operating house is 135 ft. x 400 ft., and between it and the machine shop is a large area occupied by twelve storage tracks, all connected by a diagonal cross track, having both single and double slip switches. The warehouse is located just outside the storage tracks, and is 50 ft. x 150 ft. Near it, and on a line with the main shop is the boiler house, in which is a battery of tubular boilers which generate the steam for heating the buildings.

The iron working tools in the repair department are driven by power derived from a 50 h.p. electric motor, which is belted to overhead shafting. There is also a motor of equal capacity for operating the wood-working tools in the carpenter department. This motor is located beneath the floor, as is also the main shafting, so that the individual tools are driven by belts that come up through the floor. In the machine shop the iron-working tools occupy one

INTERIOR OF REPAIR SHOP, SHOWING TOOLS, DISMANTLING PITS, TRAVELING CRANE AND TRANSFER TABLE

Each engine foundation contains about 350 cu. yds. and is quite complicated in shape. If brick work this would have cost at least $6 per yard, while the actual cost in concrete was 50 cents for material and labor in erecting and removing the forms, and $4 for the concrete itself.

REPAIR SHOP AND CAR HOUSES

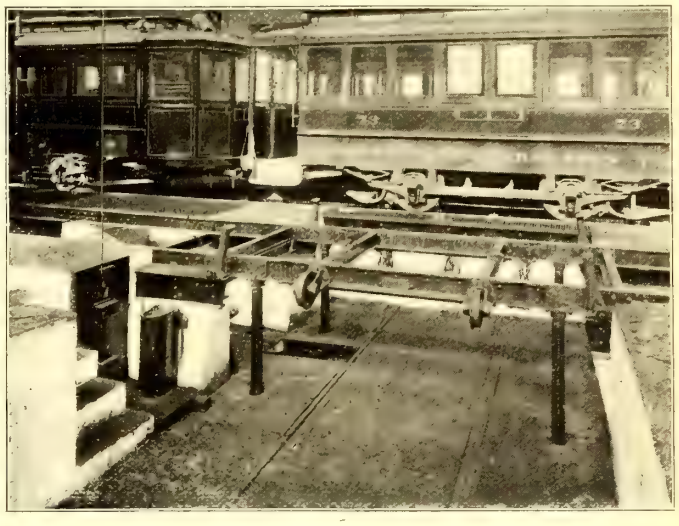


The company has six new car houses, conveniently located in different parts of the city, and all have the same general equipment. The repair shops and principal buildings, however, are located on Frankstown Avenue, and are known as the "Homewood Car Shops and Houses."

This station comprises four large buildings, with two small buildings, all of brick, with the roofs supported by steel truss riveted girders of the Fink type, and all about the same general design. The three main buildings are placed in line with each other in the direction of their longest dimension, and are all of the same width. The first is known as the storage house, and is 135 ft. x 220 ft. with a

side of the floor to the left of the main bay, and adjoining this space is the winding department. The tool equipment consisting of drills, planers, lathes, wheel-boring machines and slotters is very complete. There is also a lathe equipped with an axle key seating device. Along one side of the room adjoining the wall, a space is fenced off for a small tool room, which is in charge of an attendant who issues the cutting tools to the men on checks. This department is supplied with three machines for making small tools, consisting of a Brown & Sharp universal grinder, a milling machine of the same makers, and a small engine lathe.

The main floor of the repair shop, which is paved with brick, is devoted to the overhauling and cleaning of motors and the replacing of wheels. The shifting is all done by means of a traveling electric crane of 40 ft. span, and a capacity for lifting 20,000 lbs. It is operated by an attendant from a cage suspended from the main girder of the crane. The most interesting features, however, of the repair shop

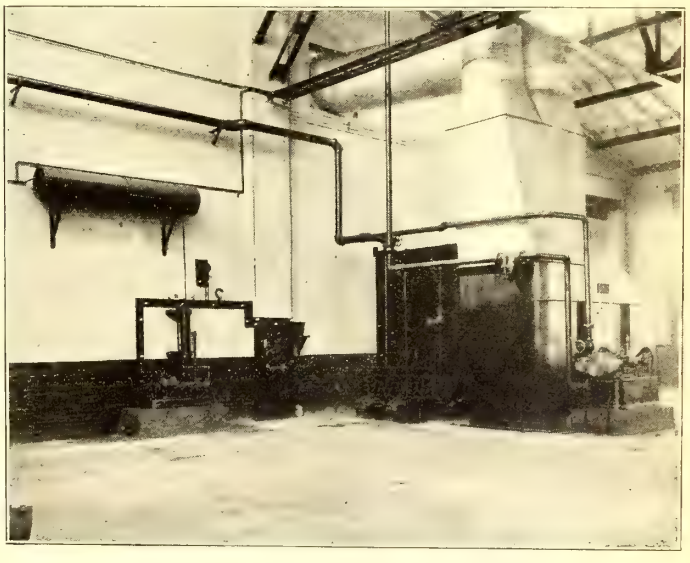


are the dismantling pits, which are located at one side of the main floor near the center of the shop. These pits are so designed that a pair of wheels, or both axles with their motors, can be removed from the truck and a new set substituted within the short space of twenty minutes. Five men only are required in this operation. The track over the pits is supported on steel girders, and is braced across, forming a truck, having small wheels on each side. This section of the track or truck is mechanically lowered or raised by means of four heavy screws, which are placed in the corners of the pit, and are operated simultaneously by means of connecting shafts and beveled gears. These screws are driven by a railway motor placed in a chamber to one side of the pit, and operated by an ordinary type "D" Westinghouse controller. In the operation of the device, the car is run over the pit, when the ends of the truck are supported by means of four folding props, which can be turned out of the way when the car is to be run on or off. The motor connections being severed and the brake mechanism unshipped, the portion of the track carrying the wheels is lowered quickly by means of the screws. When the side wheels of the section rest upon the track placed in the bottom of the pit at right angles with the car track, the truck with its load is readily rolled to one side. This brings

DISMANTLING PIT IN OPERATION

the wheels and motors into position to be readily picked up by the crane, by which they are deposited at any convenient point on the main floor. Here they are opened, inspected and cleaned. A new set of axles and motors are replaced by reversing the process. The crane deposits them on the truck, which is then run under the car, and the motor being started, each wheel is lifted to its place and secured in position, when the necessary motor connections are made.

The inspection pits of the shop are conveniently located adjoining the dismantling pits, and the rails are supported on posts, thus giving free access from one to the other, beneath the iron grating floor which covers the space between the pits. Another important machine in the shops is a Murphy wheel grinder, by means of which wheels are ground without removing them from the car. This apparatus is placed over one of the pits, near the entrance to the main floor, and is fitted with a frame work which supports a set of shafting and pulleys above the car. The truck is then supported independently of the wheels, when a portion of the truck under each wheel is removed. There are centering lathe heads on each side, so that by removing the journal box covers the axles are readily centered and left to rotate, and are operated by their own motors from the trolley current. In order to provide for proper control under these conditions, a section of the trolley wire over the cars is partly cut out of the main circuit by means of resistance coils, but there is sufficient current left in the trolley to bring the car into position. The emery



DISMANTLING PIT READY FOR CAR

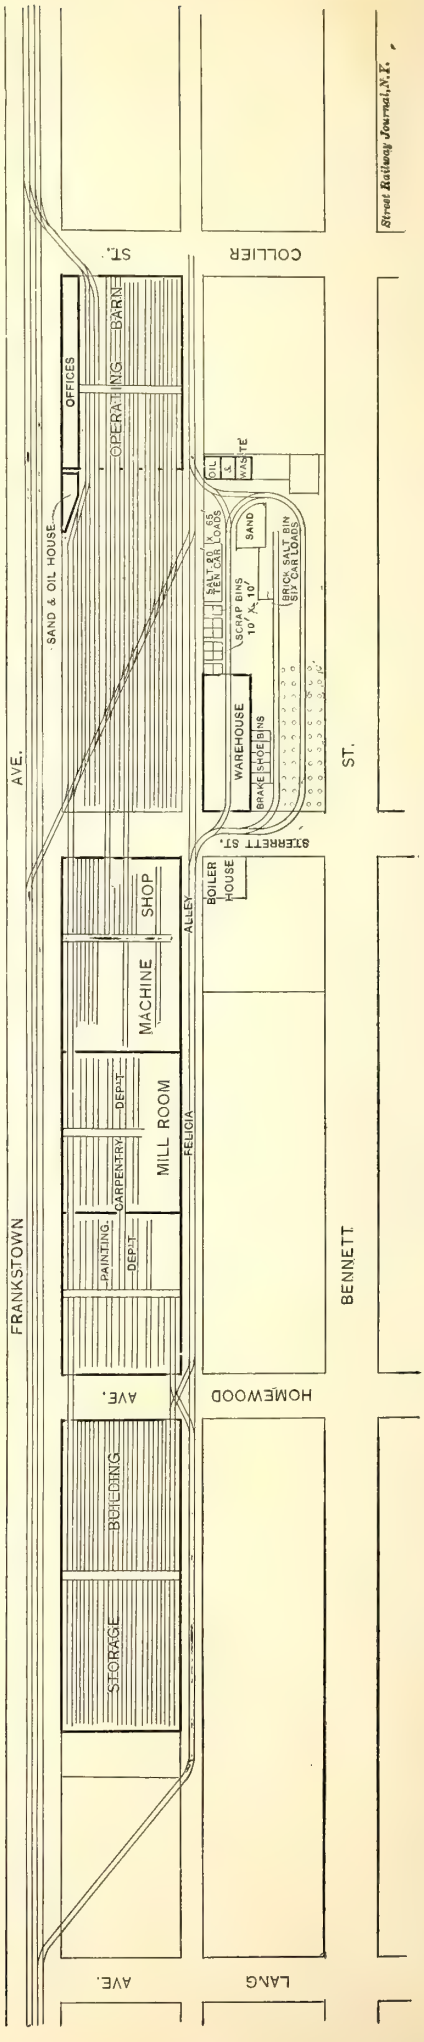
grinding wheels are so placed that they come in contact with the tread of the wheel on the under side and are revolved in a direction opposite that of the car wheels. The emery wheels are driven by belts from the overhead pulleys, the power being supplied from an electric motor placed beneath the floor, and belted to the overhead shafting.

The blacksmith shop occupies one corner of the main floor, from which it is separated by a brick partition. There are four forges with draft flues, so designed as to remove all the smoke and fumes, a feature that is rarely found working successfully in shops of this character. The equipment includes surfacing plates and the appliances usually found in this class of shops.

Another interesting feature is the method of heating the

HEATING AND VENTILATING FAN, AIR COMPRESSOR AND TANK

various departments of the shops and the operating house. This apparatus consists of two large fan cases, located at the sides and at the end of the main floor of the repair department. The case incloses a nest of steam pipes, which is open on one side, when, by the revolution of the fan, which



WOOD WORKING AND ERECTING DEPARTMENT

is driven by a small steam engine attached, the air is drawn in between the heated pipes and is forced out into large mains of galvanized iron, which lead in both directions along the ceiling. They are supported by the structural portion of the roof, and are furnished at suitable distances with branch pipes which lead half way down the posts that support the structure, and open at angles, so that the heated air is delivered in a downward stream. Steam for operating the engines of the fans is brought from the neighboring boiler house previously described. A similar equipment serves for heating the operating house.

Compressed air is used for blowing out motors, for cleaning car cushions and for removing the dust and shavings from the wood-working machines. The air is led to the various stations through pipes which terminate in a section of rubber hose with suitable nozzle valves. The air pressure is generated by means of a rotary compressor, driven by a 2 h.p. motor, which is started and stopped automatically by means of a pressure regulator in connection with the storage tank. This regulator shuts off the

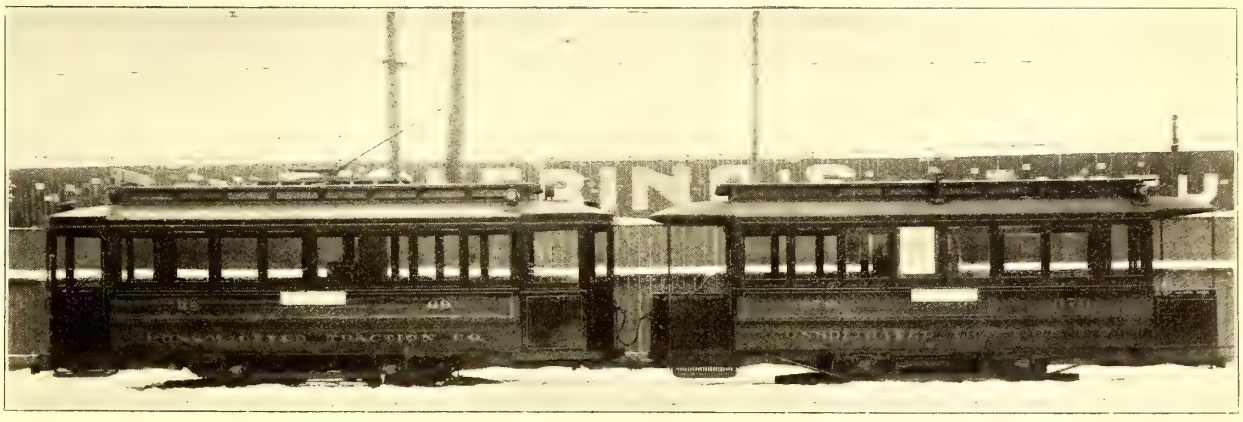
PAINT SHOP, SHOWING ELECTRIC TRANSFER TABLE, BRACKETS FOR SCAFFOLDING AND HEATING TUBES

PLAN OF HOMEWOOD CAR SHOPS AND HOUSES

motor when the pressure reaches 100 lbs., and it starts up when it has fallen to 60 lbs. The use of compressed air as above described is considered by the general foreman as a very economical feature in connection with car cleaning and repairs.

The wood-working and erecting department has a full set of wood-working tools, consisting of band and circular saws, planers, gaining and mortising machines. These are located on one side of the main floor, and are driven as before noted, by an electric motor. In addition there is an electric transfer car, which serves for shifting the cars from the main track to any of the side tracks. Similar electric transfer tables are used in the other two departments of the building.

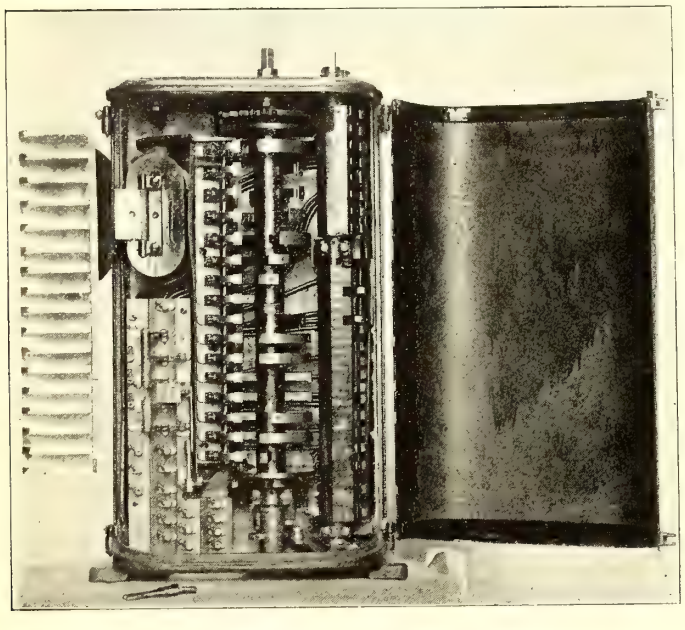
The paint shop occupies the last section of the main building. Between each of the tracks is a row of posts which are equipped with pivoted iron brackets, which when swung into position toward a car serve to support the scaffolding, by means of which the painters are able to reach the sides and roof of the car. When not in use, these brackets are swung around in line with the cars, and are not in the way of the workmen. On one side of the paint shop is a small room, fenced off by a brick wall, in which the paints are mixed, and which is fireproof. Fire buckets filled with sand are placed in suitable position with which to extinguish an oil fire, should one start. There is also a separate room for storing the sash and blinds, and a curtain department in which the necessary supplies of trimmings, etc., are kept; the main supply being kept in the main warehouse.



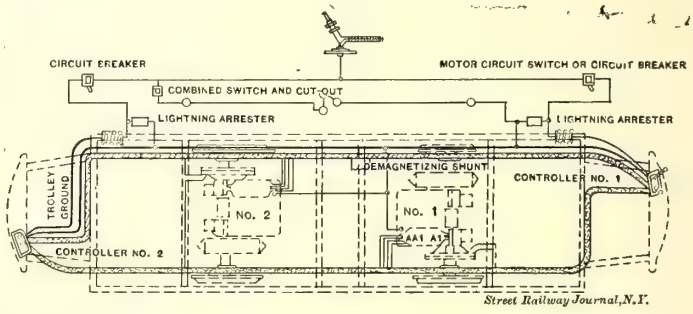
The operating house, which is also a receiving station, is provided with inspection pits, and with suitable appliances for washing and cleaning cars. The offices of the receiver and the operating foreman occupy one side of this building. These offices are finished in Georgia pine, and the counter of the receiver's office before each window is a marble slab, which furnishes a smooth and durable surface, over which the envelopes and money are passed. In the partition are suitable letter chutes through which the conductors deposit their reports. Adjoining the receiver's office is a long room designed for a waiting and lunch room for the employees. Here are suitable tables and chairs and lockers, which are arranged along each side of the room, and also in a row down the middle of the floor. The lockers number 298, and are in double deck rows. As noted above, the main buildings have about the same general structure, and for ventilating the main floors, the deck lights on each side of the monitor roof are arranged in sections, each including a number of lights, so that every other one can be slid in front of the other. The supporting frames are fitted with rollers and a track on which they run to allow this to be done. The alternate sash can be readily shifted to any degree of ventilation by means of small chains that come down near the main floor, and which are readily accessible.

The operating house, as well as all the other operating houses, with the exception of the one noted above as the storage house, are designed only as washing and inspection stations, as the cars when clean are run out and held on the storage tracks ready for service, an arrangement that saves largely in the insurance rates on the buildings. For shifting cars about the Frankstown station, dummy motor cars are employed. These cars have short bodies and are provided with electric and wheel brakes. For operating the trolley pole, the trolley cord is continuous, and passes through from end to end of the car under the ceiling with rollers so arranged that the motorman can free the trolley from the wire, reverse and return it, for running in the opposite direction without leaving the cab. These cars readily handle six or seven trail cars in a train, and pull them from the operating house to the storage tracks, where the motor cars, by means of the diagonal track above noted are able to pick up a trailer from any one of the storage tracks, and move with it to the street.

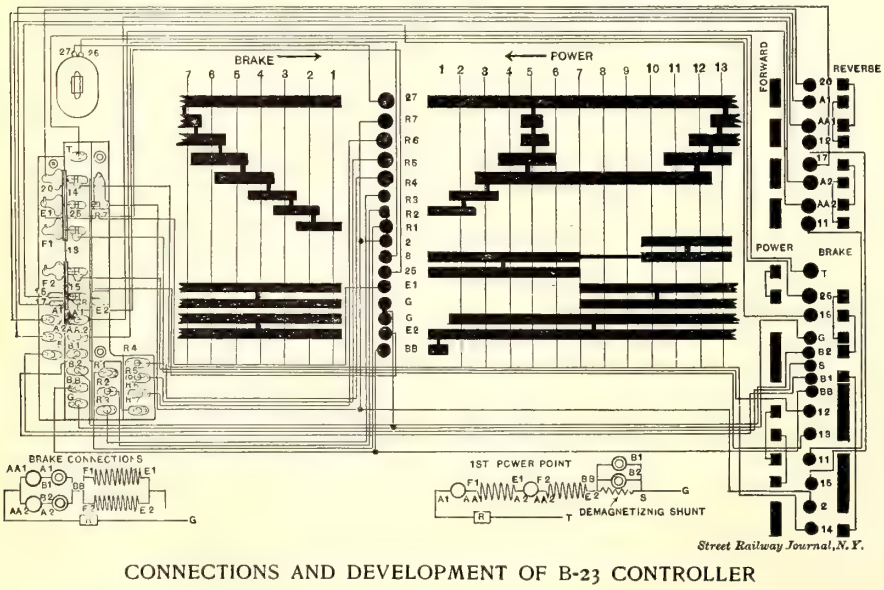
The warehouse to which all supplies are delivered has a sunken track down the middle, so that goods may be delivered to the platforms on either side from cars or trucks.



STORE ROOM, SHOWING RACKS FOR MATERIAL



ELECTRIC TRAIN WITH ELECTRIC BRAKES ON BOTH CARS



The store room is fitted with stands or racks 6 ft. x 10 ft. and 10 ft. high, which are divided into suitable boxes, bins and shelves for holding the material, one rack being assigned to each class of material. Each rack is labeled on the side toward the track in white letters, and designates the character of material which may be found therein; for instance, one reads, "rope, twine and power house supplies," another "carbon brushes and parts for standard motors," a third, " valves and pipe fittings," still another, "arc lamp supplies," and so on for each of the racks. In addition, there are shelves and drawers along the side walls in which shelf hardware is stored, and there are sliding ladders provided which give ready access to the higher shelves. Every class of articles is known by lot number, and when issued is charged up to the different departments, a most rigid system of accounts being maintained.

B–23 CONTROLLER

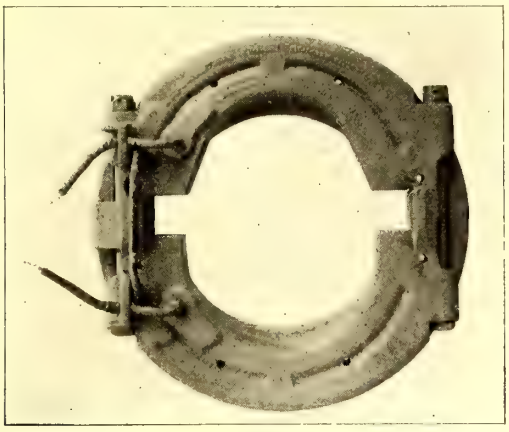
CAR WIRING FOR B-23 CONTROLLERS AND TWO MOTORS WITH ELECTRIC BRAKES

CONNECTIONS AND DEVELOPMENT OF B-23 CONTROLLER

ROLLING STOCK

In the matter of rolling stock equipment, the energies of the general manager have been directed to the standardizing of all parts and appliances. All appliances of the same kind are treated as a unit and repairs are made on a specific equipment at stated periods, without reference to the amount of wear they have sustained. The cars are all of the same design, the trucks all of McGuire manufacture, the motors Westinghouse, No. 38, with the exception of 120 new equipments mentioned below. The signal gongs are placed on the hood of the cars, and are sounded by means of a cord that hangs just above the controller handle. Recently a new type of illuminated sign has been adopted. To provide for the hauling of trailers, all the cars are equipped with the Van Dorn couplers.

Each of the 120 cars which the company has recently added to its equipment is provided with two 50 h.p. railway motors and electric brakes, manufactured by the General Electric Company. The motors are what are known as the GE-57 type, and contain all the latest improvements in construction and design. The frames are of cast steel and are fitted with laminated wrought iron pole pieces which are bolted to them. The bearings were designed with special reference to obtaining a large bearing surface and good lubrication. The armature is small and compact, having a diameter of only 14 ins. It is of the standard, iron-clad construction, such as is now universally adopted by manufacturers of this class of apparatus. The winding is of the three-coil per slot type, which has great advantages in the way of armature repairs and the ensuring of a high insulation. The weight of this motor is about 3000 lbs. complete. Each motor is fitted with a cast steel yoke, which is bolted to the frame on the commutator end of the motor. It is provided with two horns which project on each side of the axle and which are designed to support the brake shoe. The latter is of the AJ-11 type and is 26 ins. in diameter.

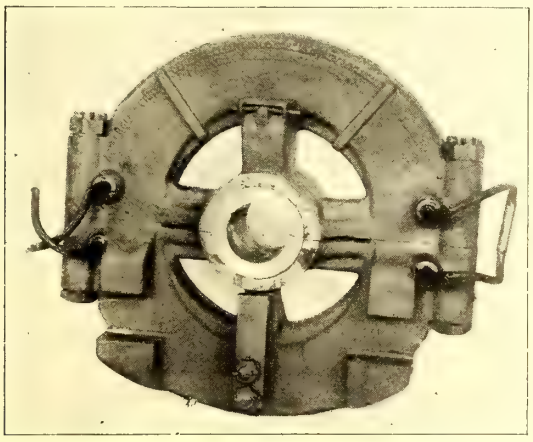


The brake disc which is keyed to the axle is the AK-18 and is, of course, of the same diameter as the shoe. The hub of the disc butts against the end of the motor axle lining, and the end play of the motor is limited by the disc which is provided with a suitable adjustment.

The controller used on these equipments is the B-23, designed for operating two 50 h.p. motors with electric brakes. The braking is accomplished in the usual manner by converting the motors into generators and passing the current thus generated through the brake shoes and regulating resistance. With this method of braking, it is immaterial whether the trolley is "on" or not. The braking effort is due to the "back" torque of the motors (acting as generators) and the friction between shoes and discs.

A good idea of this controller may be obtained from the photo-engraving showing the interior. The controller has a single operating cylinder which is rotated in one direction for power and in the opposite direction for brake.

The various motor and brake connections for power and braking are made by the small commutating cylinder shown on the right hand side of the controller. This cylinder is moved by means of a cam secured to the main cylinder shaft which engages with the lever seen at the bottom of the controller. The reversing cylinder is shown at the top of the controller on the right hand side, and is of the usual construction.

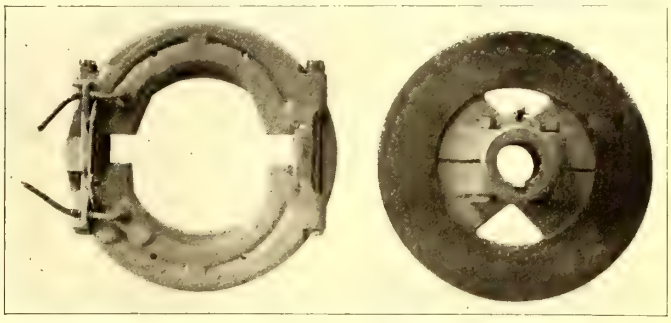


The main cylinder serves to series parallel the motors on

MOTOR CAR BRAKE SHOE (TYPE A J-11)

the "power" side and to regulate the resistance both for power and brake. As the usual interlocking mechanism between cylinders is used, all arcing takes place on the main cylinder where the efficient magnetic blow-out embodied in all controllers of General Electric manufacture, provides for its prompt and complete extinguishment.

This controller differs from some of the earlier types in the arrangement of braking connections and enables the

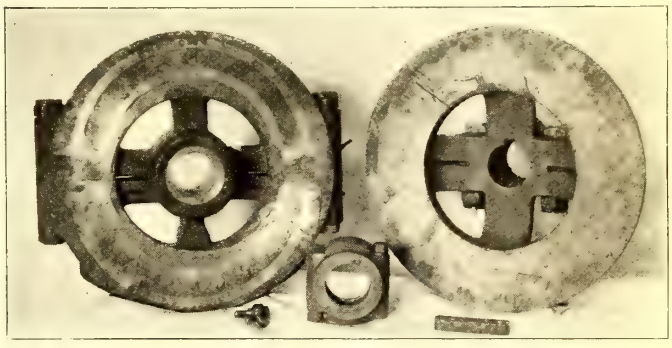


TRAIL CAR BRAKE SHOE (A J-13)

motormen to make a much quicker stop without skidding the wheels than was possible with the other types of controller, or with any form of power brake. The diagram on p. 138 shows the development of the controller and the connections of the apparatus for both power and brake.

It will be observed that the brake shoe on each axle is directly in series with the armature of the motor on the same axle. If either brake tends to lock, due to a too rapid application of the brake, the axle will cease to turn, or, at least, slow down, with the result that the armature in series with the shoe ceases to generate as great a voltage as the armature of the other motor.

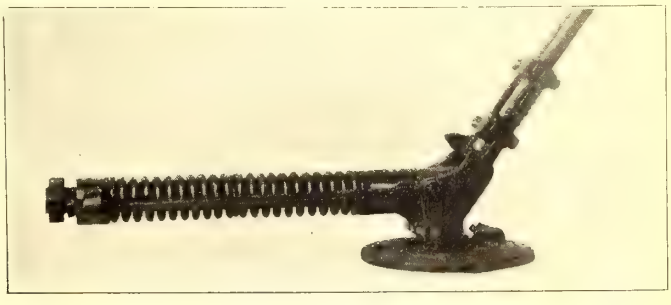
The natural result is, that current will pass through the locked shoe in the reverse direction and demagnetize it, allowing it to release. As this action is entirely automatic, it is practically impossible to skid the wheels for more than a foot or two, which is not sufficient to cause a flat wheel. The maximum braking effort that can therefore be applied is dependent solely on the friction between wheels and track.



The shoes are demagnetized in the usual manner by

MOTOR CAR BRAKE SHOE AND DISC

shunting a portion of the current on the first power point through them in a reverse direction. This current allows them to release and drop away from the disc.



Provisions are also made for the use of electric brakes on the trailer cars. The shoe used is of the axle suspended type, being mounted directly upon the car axle. This shoe is the AJ-13 and is provided with brass axle lining and grease cup. The brake disc is the AK-13. Both shoe and dics are 28 ins. in diameter and they are mounted on each axle of the trail car truck. The shoe is adjusted by an axle collar and an adjusting screw, passing through a U bolt which is screwed into the axle. The shoes are kept from

TRAIL CAR SHOE AND DISC

revolving by means of a bar which passes between the horns shown on the lower half of the shoe.

Connection between motor and trail car is made by means of a special coupler which contains the lighting connection as well as the two brake connections. The

U. S.-6 TROLLEY STAND

sockets are secured to the dashers of the two cars and connections made by means of a flexible lead with a plug at each end. The trail car shoes are connected in series, and when in use are connected between the common lead from

the two motor car brake shoes and the equalizing connection of the motor fields. Referring to diagram of the controller, these shoes are connected in the wire marked BB.

The trolley bases are of the new type recently brought out by the General Electric Company, and known as the U. S.-6 base. The interesting feature of this type of base is the use of a single compression spring which serves the double purpose of a pressure and a buffing spring. A view of this trolley is shown on page 139, from which the action of the base will be readily understood. The buffing collar is seen on the inner end of the spring guide and is forced against the spring by the two lugs on the inside of the swivel head. The stud is very long, insuring an easy swiveling action and allowing the wheel to follow the wire exceptionally well. The inside of the swivel head is fitted with a brass bushing, which reduces the swiveling friction and can be easily replaced when worn out. The minimum height of this base is 6 ins. with the pole in a horizontal position. The cars are provided with circuit breakers connected according to our latest method, the circuit breaker at either end of the car being in circuit only with the controller at the same end. These circuit breakers are of the "MQ" type and contain a magnetic blow-out and other features found in circuit breakers of the General Electric manufacture.

ORGANIZATION

The business affairs of the Consolidated Traction Company are chiefly under the direction of C. L. Magee, president, while the operating department, as well as the electric and mechanical features, are in charge of G. F. Greenwood, with the title of chief engineer and general manager.

CONTRACTORS, ETC.

Some of the contractors and manufacturers of the material required for the erection of the new buildings, and the equipments noted in the accompanying description include the following: The Pennsylvania Iron Works Company of Philadelphia, engines and the auxiliary steam equipment; Babcock & Wilcox Company, boilers; Westinghouse Electric & Manufacturing Company, generators; Jones & Laughlin, Pittsburg, structural steel for roofs and coal bin; Alfred F. Moore, Philadelphia, lead covered cables; John A. Mead & Sons, New York, coal conveyors and automatic weigher; Electric Storage Battery Company, Philadelphia, storage batteries; The U. Baird Machinery Company, Pittsburg, some of the iron working tools; J. A. Fay & Co., Cincinnati, wood-working tools; Marlin & Co., Pittsburg, exhaust steam headers, roofing and ventilators; Pawling & Harnischfeger, Milwaukee, electric traveling cranes; Laclede Car Company, American Car Company, Union Car Company, cars; A. French Spring Company, Pittsburgh, car springs.

◆◆◆

It has been proved that it is usually a waste of time, and very little has been accomplished, by attempting to instruct motormen and conductors other than in the simplest ideas of electrical problems, for while on some roads there may be a number of old motormen who have a fair idea of electrical equipments and whom it would probably be safe to allow to locate existing troubles, it would be difficult to draw the line between the men competent in this direction and those wholly lacking in such knowledge. I know of nothing more distasteful to passengers unwillingly detained than sitting in a car impatiently waiting while a motorman works over some part of the equipment in a vain endeavor to locate some trouble, the very nature of which he has not the faintest idea, and quite likely, at the same time, interfering with the movement of several other cars. From paper at the Boston Convention, 1898.

Interurban Electric Railway in Titusville, Pa.

A 10-mile electric railway has recently been completed in northwestern Pennsylvania, connecting the towns of Pleasantville, East Titusville, Titusville and Hydetown. The road was built and is operated by the Titusville Electric Traction Company, which, in 1897, obtained a 999-year charter from the State. It was opened for business on June 3 of last year, carrying passengers from Pleasantville to Titusville, and in November, the 4 miles to Hydetown were finished. Titusville is the largest of the four towns, and has a population of 10,000. Pleasantville, with its population of 1200, does its shopping and marketing in Titusville, as does East Titusville and Hydetown. The total population of the four towns is about 15,000.

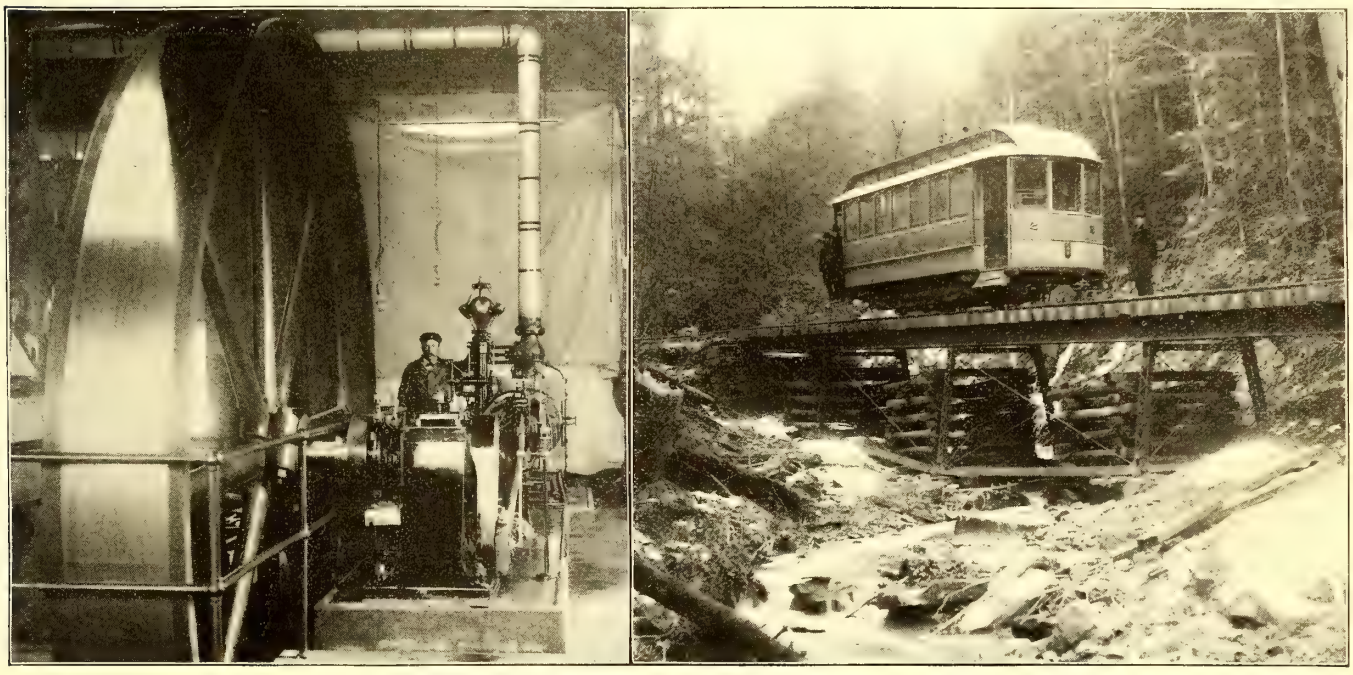
Titusville is famous for having been the center of the great oil excitement of the early sixties. Petroleum was discovered here, and in a few years, what had been a straggling hamlet, became a bustling young city. Gradually the production of oil has lessened in the vicinity of Titusville, and the city has suffered a reaction. Several years ago, however, a Board of Trade was organized, and through its efforts and those of the Industrial Association the city is now enjoying a more wholesome and lasting prosperity. Among its leading industries are several large iron-working establishments; a tannery, which employs several hundred men; oil refineries, and a silk mill.

For a number of years the people of Pleasantville and Titusville have been desirous of having the two towns in closer communication than was afforded by a stage line and George B. Dunham, of Pleasantville, took the initiative and succeeded in interesting R. D. Stoelzing, of that place, M. B. Dunham and A. J. Hazelton, of Warren, Pa., and a corporation was formed with a capital of $100,000. A survey was immediately made and work was begun in July, 1897. Pleasantville is 6 miles from Titusville, and the new company was obliged to purchase the right of way for almost the whole distance from the eastern city limits of Titusville to Pleasantville. Two miles of the road run through a deep gorge along the path of a small but turbulent brook. The engineers at first thought it would be an impossibility to build the road through this gorge, and it was only accomplished after much blasting and bridging were resorted to, and finally the course of the stream was changed near the entrance of the gorge. About 1 mile from the entrance of the gorge the company has leased 60 acres of woodland, which is being converted into a park. The place is one of great natural beauty, and, with the attractions that the company offer, it is expected that it will become a favorite resort, and will do much to increase the road's earnings. Next summer it is proposed to construct, near the park, an artificial lake, in the center of which will be a large electric fountain. The lake will be large enough to afford boating and bathing.

The company's power station is at East Titusville. It is a substantial brick building 74 ft. x 58 ft., of which the engine room occupies 58 ft. x 35.5 ft. and the boiler room 38 ft. x 39 ft. A steel stack 4 ft. in diameter is used. The floor of both rooms is of cement. Since the road has been in operation one engine has been employed. It was built by the Atlas Engine Works, of Indianapolis, and is of the Corliss type, 16 ins. x 32 ins. During the past month a larger engine, 24 ins. x 48 ins., of the same type and make, has been installed and is now running. The smaller engine will be used as auxiliary in case of breakdown or when the load is too heavy for the newer engine. The bed plate is of the girder form, known as the "Corliss bed plate." It is cast in a single piece, unusually massive and rigid, the main shaft-bearing having removable parts with

wedge adjustment. The ends of the cylinder, which contain the valve chambers and the steam and exhaust parts, are cast and finished separately from the cylinder proper, through which the piston traverses. The parts are so constructed and bolted together that the piston travels over no joint, while the clearance remains as low as in the usual form. The advantages afforded by this construction are a more perfect bore free from flaws and shrinkage strains, which the presence of small cored passages is apt to engender, and that, being made to gages on the interchangeable plan, it is possible to renew, without delay and at small cost, a part injured by accident, which otherwise might mean the loss of the entire cylinder. A steel plate lagging, which leaves a space packed with non-conducting material, covers the cylinder. The steam and exhaust valves are of the usual rocking or Corliss type, but are so constructed that they open their ports in two places, thus giving the full opening with half the usual motion.

In the valve gear of the engine a wide departure from the ordinary is seen. The steam valves are operated from the usual wrist plate, driven by an eccentric on the main shaft, but a separate eccentric is used for the operation of the exhaust valves. The cross-head and crank-pins are of steel, and have unusually large wearing surfaces.



The main shaft is of hammered iron, and the engine is provided throughout with the most improved automatic sight-feed oiling devices and is adapted for continuous working.

Two of the General Electric Company's generators have been installed, and are belted to the engines. The smaller one, a 110 kw., has furnished the current since the completion of the road. The new engine is connected with a 325-kw. generator, which is now in operation, the smaller one being reserved for emergencies. A General Electric Company's switchboard is used, fitted with instruments made by the Weston Electrical Instrument Company.

The fuel used in the three 150-h.p. boilers is natural gas furnished by the Oil City Fuel Supply Company. This is a much cheaper fuel at Titusville than coal would be, costing 10 cents per 1000 cubic feet. The average monthly consumption of gas since the road began operation is 52,000 cubic feet. The steam pressure carried averages 100 lbs. The gas requires but little attention, one man only being in attendance in the boiler room. The feed-water heaters and a 7-in. x 4½-in. x 10-in. pump in the boiler room were made by the Stillwell-Bierce Company.

The trolley wire used was made by Washburn & Moen, and is No. 00. The poles are of chestnut, 50 ft. long, with a 7-in. top, and bracket construction is used almost entirely. The track in the city is laid with 60-lb. girder rails 60 ft. long. Outside the city 70-lb. T rails are employed. Hewn ties, 7 ins. x 7 ins. 8 ft., are used generally in the country. Within the city limits the ties are sawed 6 ins. x 8 ins. x 8 ft. The cost of track construction averaged $10,000 per mile.

A temporary wooden car barn adjoins the power house and accommodates the four cars. The American Car Company made the four closed cars now in service. They are full vestibuled, with 20-ft. bodies, 30 ft. over all. Three of the cars are finished in cherry, the other is in white ash. Extra-heavy extension Peckham trucks are employed, each being equipped with two No. 49 Westinghouse motors. The New Haven registers are used, and the cars are heated by the Johns system. The New York Car Wheel Company's wheel 33 ins. in diameter, with 2¼-in. tread are used. The average life of the wheels on this road is about 20,000 miles.

VIEW IN ENGINE ROOM AND ALONG LINE, TITUSVILLE

The cars travel at a schedule speed of 15 miles per hour, although on some parts of the road over 25 miles is reached.

The maximum grade of the road is 8 per cent, which is reached in the gorge. It is practically an up-grade from Titusville to Pleasantville. The western end of the line is mostly a light grade. Two steel bridges were built in the gorge, one 168 ft. and the other 80 ft. long.

The fare charged in the city of Titusville is 5 cents, and outside averages 2½ cents per mile. Over $6,500 net was earned in the first six months of operation.

The officers of the company are: President, B. D. Dunham; secretary and general manager, G. H. Dunham; chief engineer, A. A. Robertson. The main office of the company is at Pleasantville.

Train Resistance

BY JOHN BALCH BLOOD

I have read with interest the formula for train resistance proposed by John Lundie in the last issue of the Street Railway Journal, but think that investigation will show that the method used by Mr. Lundie for obtaining his formula, i. e., by coasting, is not new. In fact it has now been practically abandoned, as it does not make the test under conditions of service, either as regards the condition of the bearings and the forces acting, or as regards the speeds. All engineers who are acquainted with the subject will know the benefits and disadvantages of this method, and the predisposition would be against it rather than in its favor. It is mentioned that the results indicated in Fig. 1, in the article last month, are obtained directly from 150 or more observations. It would seem that the results should check better within themselves, if such were the case. In the case of the 80-ton train the variation of the tangent of the angle is about 6 per cent.

Train resistance has been a subject which has figured largely in mechanical engineering. A great many men in this country and in Europe have made attempts to formulate it in some convenient manner. Some of these men have been eminent technically, while others have been interested in the subject more from an operating or practical standpoint. Most have desired to make an empirical form of an equation which would best represent the results obtained by experiment, irrespective of the different factors which go to make these results; few appreciated that train resistance was a combination of factors, and therefore if any one factor was pre-eminently above the average, the whole empirical formula would fall. Probably most of the people, who have worked on this subject, appreciated the different factors which go to make up resistance as such, but judging from their formulæ they did not appreciate the function of these factors, and their relative amounts, and also that they were liable to occur in different proportions under different conditions.

There are two methods of measuring this resistance. One, by observing it as a function of the retardation or acceleration, and the other by measurement direct as the resistance pull. The first mentioned was the original method, and the one almost universally used for twenty years. Recently actual measurement by dynamometer or indicator cards on the engine has been more frequent. The first method can be applied in three different ways: First, by bringing the train to a known velocity and measuring the distance to a full stop, then by calculation with averages the train resistance can be computed. After a while it was found that the average should be calculated as an average of the square of the velocity rather than the direct function.

Another method used was to bring the train to a known velocity and measure the loss in velocity at stated intervals until it came to a standstill. Still another method was by calculation from acceleration or retardation in connection with a force of gravity, on an up or down grade. In the second method of determining this resistance, namely, by direct measurement of the pull, this is done in three ways, namely, by use of a dynamometer, by calculation from indicator cards on steam engine, or by calculating from the power curves of an electric motor. The dynamometer and indicator have been used with very good results. The method of calculating from an electric motor has not been used to any great extent, principally from reasons that the speed attained in present installations are not high enough to give reliable points for use in a formula.

The writer made some calculations a few years ago from tests which were conducted quite accurately on the Metropolitan West Side Railway in Chicago. The tests were not conducted for this purpose, and therefore the results are all the more gratifying because they check so accurately. The tests show that between 22 and 26 miles per hour the resistance was from 17 to 18 lbs. per ton.

With regard to the different methods of computing, it can be said that the second general method of measuring absolutely the pull is by far the best, as the conditions are as in practice. The first general method has been practically discarded, because the bearings are not in normal condition on account of the fact that during retardation the force goes from the track and the friction of the bearings is constantly diminishing with the speed, whereas in the case of direct measurement with the speed constant the power is transmitted through the car, and the resistance force is constant at the time of measurement. If the speed is not constant during measurement, allowance must be made for the acceleration or retardation.

Calculations from electric motors seem to me to present the best chance for accuracy.

We will now consider a number of the formulæ in a chronological order:

In 1854, D. K. Clark published a formula based on the experiments of Mr. Gooch, during some previous years. The formulæ given out by him were as follows:

$$R = 8 + \frac{M^2}{171}$$

$$R' = 6 + \frac{M^2}{240}$$

M = Speed in miles per hour.

R = Total resistance of engine tender and train in lbs. per ton of 2240 lbs.

R′ = Resistance of train above in lbs. per ton of 2240 lbs.

The formula now referred to as Clark's formula with tons of 2000 lbs. and giving resistance for train only is

$$R = 7.14 + \frac{M^2}{191.5}$$

Experiments were conducted at low speeds, and condition of the bearings and tracks was not by any means as it is at present. It was soon found that the locomotive had more resistance than the ordinary train.

Rankine proposed a formula which was as follows:

$P = [5.35 + .27 (v - 10)] (T + 2E)$.

P = resistance in pounds.

v = speed in miles.

T = weight of train in tons.

E = weight of engine in tons.

Transposing and using our nomenclature, we have for resistance, exclusive of engine

$$R = 2.6 + .27\ M$$

It will be noted here that he assumed that the locomotive would have just twice the resistance of the rest of the train, a very arbitrary assumption. This formula was based on low speeds.

Searles proposed:

$$P = 4.82\ W + .005\ v^2\ W^2 + .00047\ v^2\ E^2$$

W = weight of train plus locomotive.

E = weight of locomotive.

v = speed.

P = resistance in pounds.

This reduced to the form as follows if we assumed weight of locomotive 35 tons:

$$R = 4.82 + .005\ M^2 + .6\frac{M^2}{T}$$

This formula has been complimented and recommended quite largely. He appreciated that there was a factor in the resistance which was not a direct function of the weight, and also that the locomotive gave more resistance than ordinary cars. The third factor of the formula takes these two facts into account. This formula was developed when low speeds were in vogue:

Welkner in Bavaria as a result of his experiments gave the following formula:

$$W = 3.125 + .00079\ v^2$$

W = kilograms per tonne (1000 kg.)

v = speed of train in kilometers.

Transposed into English units

$$R = 6.25 + .004\ M^2$$

These tests were made with low speeds.

The Eastern Railway of France conducted quite elaborate tests and as a result gave four formulæ as follows:

(1) $W = (1.65 + .05\ v)\ Q$

(2) $W = (1.8 + .08\ v)\ Q + .009\ A\ v^2$

(3) $W = (1.8 + .08\ v)\ Q + .006\ A\ v^2$

(4) $W = (1.8 + .14\ v)\ Q + .004\ A\ v^2$

Q = weight of train in tonnes of 1000 kg.

v = speed of train in km.

A = cross section train square meters.

W = resistance in kg.

Stating that the first for use with freight trains from 12-32 km. per hour; the second for use with mixed freight and passenger trains run from 32-50 km. per hour, the third for passenger trains run from 50-65 km. per hour, and the fourth for express trains running 70-80 km. per hour.

These engineers appreciated that there was a factor due to wind resistance which was independent of the weight of the train, and which varied as the square of velocity multiplied into the cross section of the train.

Transposing, and bringing these formulæ into form for comparison we have as follows:

(1) $R = 3.3 + .161\ M$

(2) $R = 3.6 + .258\ M + .259\ \frac{M^2}{T}$

(3) $R = 3.6 + .258\ M + .173\ \frac{M^2}{T}$

(4) $R = 3.6 + .451\ M + .115\ \frac{M^2}{T}$

R = lbs. per ton.

M = miles per hour.

T = weight of train tons (2000 lbs.)

Cross section of train taken constant as 10 sq. yards.

First for 7.5-20 miles.

Second for 20-31 miles.

Third for 31-40 miles.

Fourth for 43-50 miles.

The formula proposed by Mr. Wellington is as follows:

$$P = 4\ W + .28\ v^2 + .03\ v^2\ C + .005\ v^2\ W$$

Where C = number of cars in train and the rest as before. This reduces to

$$R = 4 + .005\ M^2 + (.28 + .03\ C)\frac{M^2}{T}$$

Or, if we take 6 as the number of cars in average train, we have

$$R = 4 + .005\ M^2 + .46\frac{M^2}{T}$$

The first term of this formula is for friction of the journals between the wheel and the rail, a quantity which is independent of the speed. The second factor is what he terms head resistance, or the resistance of the first car on account of the wind pressure. The third factor is to represent side resistance, or the resistance offered by the atmosphere to the side of the train. The fourth factor he terms oscillating resistance, or increase in journal or rolling friction depending on the speed. When we combine, we have here two factors which are proportional to the weight of the train, and two which are independent of it.

From the "Engineering News," 1893, results are given, which if put into a formula would be as follows:

$$R = 2 + .25\ M$$

D. L. Barnes has given as result of his observations

$$R = 4 + .16\ M$$

These two formulæ have been developed in connection with higher speeds up to 100 miles per hour.

Dodd proposed, STREET RAILWAY JOURNAL, September, 1898:

$$P = (18 + .2v)\ E + (7 + .2v)\ T$$

This is equal to the following if the train only is considered:

$$R = 7 + .20\ M$$

Lundie gives as a proposed formula:

$$R = 4 + S\left(.2 + \frac{14}{35 + T}\right)$$

Or, transposed,

$$R = 4 + .20\ M + \frac{14\ M}{35 + T}$$

Mr. Lundie's formula was gotten from tests with the

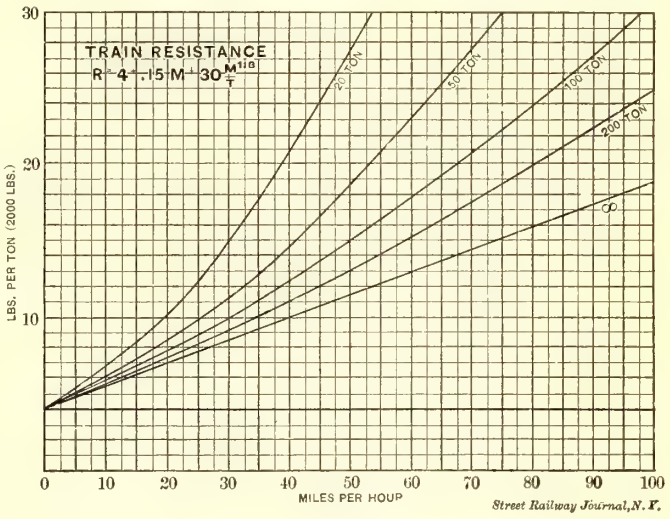


FIG. 1

cars using electric motors. The friction of the electric motor gears and eight extra bearings per car is a considerable factor in the total friction. His formula, therefore, would give too high results.

In ordinary train resistance there are three factors. The journals of the cars, the friction of the wheel on the rail, and the air resistance. In Mr. Lundie's test he should also consider a fourth, namely, the friction of the gears, and the bearings of the motors. All of the cars which he tested had mounted on one of the trucks two 60 h.p. motors. The friction of gears and bearings of these motors when running at 20 miles an hour is about 1400 watts, or 2800 watts per car. This is equivalent to 3.74 h.p., or, reduced to the term of train resistance, would be equivalent to 3.5 lbs. per ton. From Mr. Lundie's curve the train resistance at 20 miles is 12 lbs. per ton, with a 20-ton unit; subtracting this factor of motor friction, we have as an actual train resistance, according to the ordinary understanding, 8.5 lbs. per ton. We therefore see that in this case Mr. Lundie's error by assuming motor friction as nil, is 41 per cent. of the actual train resistance.

Journal friction, according to the laws of friction, should be practically constant in torque at all speeds. The friction of the wheel on the rail varies as first power of the speed. The resistance due to air varies as a higher power than the

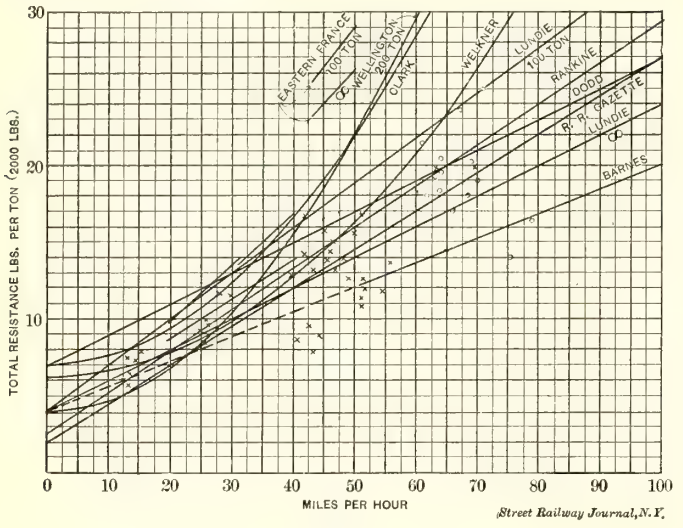

FIG. 2

first of the speed, and is independent of the weight of the train. The resistance due to the motor friction is compound, the motor bearings which would be practically independent of the speed and the gears which would increase with the speed.

From the best information which I have at hand, the calculation for the friction due to the motor would be

$$G = .1\,M + 1.5$$

where G is equal to the motor friction in lbs. per ton, and M is equal to the speed of the car in miles.

For comparison we present all these formulæ in a table:

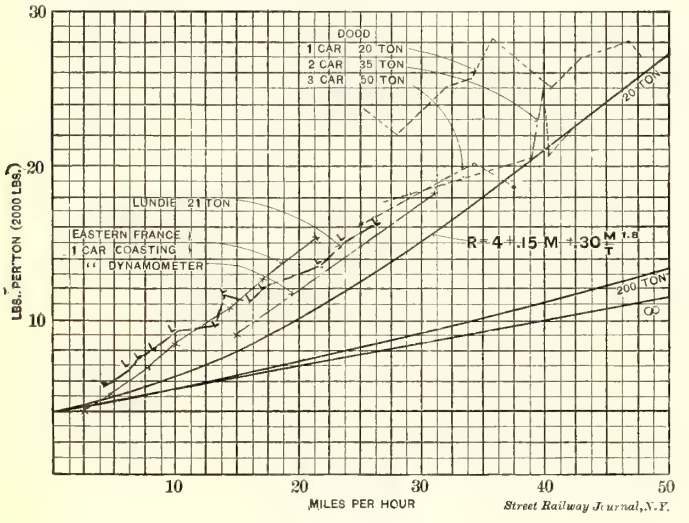

FIG. 3

COMPARISON OF FORMULÆ.

Clark, 1854, $R = 7.14 + .006\,M^2$

Rankine, $R = 2.65 + .27\,M$

Searles, $R = 4.82 + .005\,M^2 + .6\frac{M^2}{T}$

Welkner, $R = 6.25 + .004\,M^2$

Eastern Ry, France, 1885, $R = 3.6 + .258\,M + .29\frac{M^2}{T}$

Wellington, $R = 4 + .005\,M^2 + .46\frac{M^2}{T}$

Engineering News, 1893, $R = 2 + .25\,M$

Barnes, $R = 4 + .16\,M$

Dodd, $R = 7 + .20\,M$

Lundie, $R = 4 + .20\,M + \frac{14\,M}{35+T}$

R = resistance in lbs. per ton (2000 lbs.)
M = miles per hour.
T = weight train in tons (2000 lbs.)

We note that at the start the speed in the second power was used. Rankine, however, used the first power. The errors of experiments were so large that at low speeds it was almost immaterial whether the first or second power was used and the coefficients. Most of these formulæ with the second power were found to give too high results at speeds above 50 miles per hour, therefore a reaction came and new formulæ with a speed as the first power are being recommended. Various modifications have been suggested. The engineers of the Eastern Railway of France had formulæ with both a first and second power of speed as a factor. They apparently appreciated that the second power was too high a power for the wind factor, and therefore have given out formulæ with small coefficients for the higher speeds. These engineers may not have appreciated that the power of the air resistance component should have been between one and two, but they certainly did find that

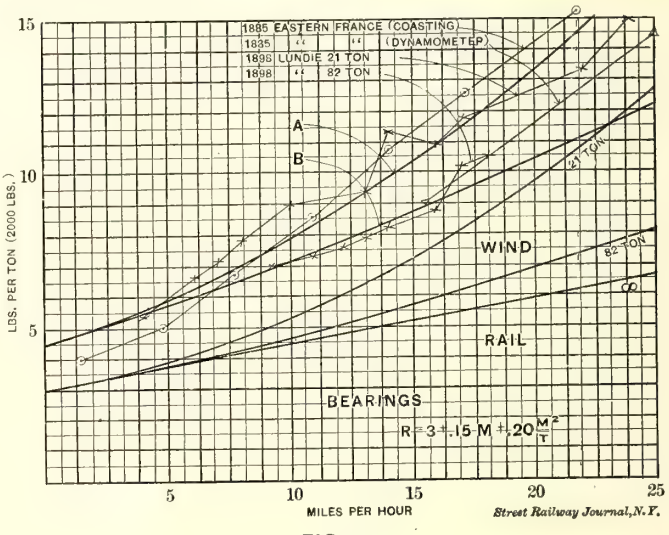

FIG. 4

using the same formulæ for high and low speeds was impracticable.

If we analyze the case we will find that there are three main factors which go to make up this resistance. First, the resistance of the journals, which is approximately constant at all speeds. Second, the friction between the rail and the track which varies approximately with the speed. Third, the wind resistance which is independent of the weight of the train, and which varies as a function of the speed to a power between the first and second.

The general form of the formula would then be as follows:

$$R = B + W\,M + A\frac{M}{T}$$

Where

R = resistance.
M = speed.
T = weight train.

The coefficients

B = journal coefficient.
W = wheel and rail coefficient.
A = air resistance coefficient.
n = exponent of air factor, which should be determined by experiment. It is between 1 and 2.

It is folly to attempt to give a formula which would be universal. We must place a proper coefficient in our for-

mula depending upon the quality of the different pieces of apparatus in connection with the friction. If we have well-worn, nicely made bearings, with low surface pressures, the factor B can be taken from 3 to 4. If the cars are new, bearings not worn, or the pressures abnormal, this factor would have to be taken as 5 or 6. With rails of a proper shape, of sufficient weight, well laid, and a wheel with proper flanges, and perfectly round and the right size, the second factor W would be .15. If these conditions were discounted this factor would increase. In the third term of the right hand member of the equation the factor A would depend upon the cross section of the train, and the exponent n, should be determined by experiment. The exponent n is certainly greater than 1, and in all probability is less than 2. Of course, if we make this exponent anything from an even number it makes the formula hard to use in calculation. At the same time, in high speeds the air resistance becomes of considerable moment, and must be determined accurately.

In Fig. 4, I have attempted to suit this equation to the results of Mr. Lundie, using in the air resistance term the

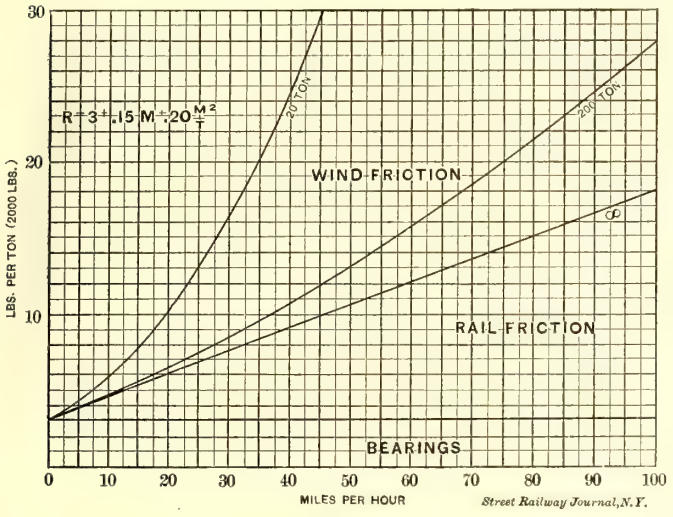

FIG. 5

second power in order to get a simple equation, and I have as a result the following:

$$R = 3 + .15\,M + .20\,\frac{M^2}{T}$$

Fig. 5 shows the equation plotted for all speeds up to 100 miles per hour.

The following table will show the relation of the friction to the different component parts, both with a 21-ton and an 82-ton train:

TRAIN RESISTANCE WITH MOTORS.

			Air.			Total.	
M.P.H.	Bear.	Rail.	21 T.	82 T.	Motor.	21 T.	82 T.
0	3	0	0	0	1.5	4.5	4.5
5	3	.7	.2	.06	2.0	5.9	5.8
10	3	1.5	.9	.2	2.5	7.9	7.2
15	3	2.2	2.1	.5	3.0	10.3	8.7
20	3	3.0	3.8	1.0	3.5	13.3	10.5
25	3	3.7	6.0	1.5	4.0	16.7	12.2

It will be seen that the motor friction is a very important factor throughout the whole range.

To the best of my knowledge in applying the most reliable data which I have at hand, I would say that the formula which would represent good practice would be as follows:

$$R = 4 + .15\,M + .30\,\frac{M^{1.8}}{T}$$

This is given in curves in Fig. 1. Fig. 2 shows how the various formulæ compare, and also shows points from best results which I have at present at hand. This figure will show how the curves compare with the results and with themselves. From this it will be seen that it is immaterial for trains over 200 tons, and running at less than 40 miles an hour, whether the exponent of the speed term in the equation was of the first or second power. The variation from the curves is less than the accuracy of the experiments among themselves. Again, the variation of the proper coefficients would, in all probability, be greater than the variation from the curve itself.

Fig. 3 shows how this formula agrees with tests of trains of light weight. I have plotted here in this figure results of some tests made on the Eastern Railway of France, some ten years or so ago. These were made with single cars; in all probability 6-wheel cars, and of a weight considerably less than 20 tons. I have also plotted results of a test by Mr. Lundie on the Chicago and South Side Elevated Railway. These results contain, beside the usual resistance, an additional resistance of the gears of the motors, and of the bearings of the motors. There are two motors on each car, and this resistance is quite material compared with the total. From calculations from absolute tests at 20 miles, this resistance would amount to 3.5 lbs. per ton. Taking this into account, it will be seen that these results agree quite well with this formula.

I have plotted also, in Fig. 3, results of some tests mentioned by Mr. Dodd in a paper read before the Civil Engineers' Club of Cleveland, published in the STREET RAILWAY JOURNAL for September, 1898. These tests, on account of their variation, would not seem to be very accurate. In all probability, although it is not directly stated, there is a motor friction to be taken from these results.

[For a further discussion of this subject, see pages 149 and 150 of this issue.—Eds.]

A French Account of an English Accident

One of the French electrical papers thus humorously describes a recent accident in one of the underground railways in London:

Even under ordinary circumstances, it is far from reassuring for the timid traveler to traverse tunnels, especially when these tunnels are some 60 ft. below the surface of the earth, but when the box in which he is enclosed stops suddenly with no indication of ever starting again, no passenger ought to be considered a coward if he begins to feel cold chills run up and down his back. The situation is certainly one which does not have many cheerful features in it. This is what happened the other week to a crowd of Londoners who were going to see a procession of the Guards returning from the Soudan. The trains, heavily loaded, were passing slowly through the single tube which extends under the Thames, and were approaching Waterloo station, when, all of a sudden, they came to a stop. Immediately the ventilation in the tunnel, which is secured by the rapid movement of the trains, ceased. The poor passengers began to get suffocated, the lights went out and the darkness added still more to their terror. Finally, half-asphyxiated, they climbed out of the cars in a crowd and on foot traversed the distance through the tunnel to Waterloo station, about half a mile away. The trouble was caused by the electric motors, which, not receiving sufficient current to propel the heavily loaded cars, refused entirely to work. It is fortunate that the accident happened in England, where stolidity is so common and everyone is cold blooded, as otherwise the accident might have had a more serious termination.

In dealing with the inspection of cars in the car house, we believe better results can be obtained by giving to each man some particular branch of the work, rather than assigning to him a certain number of cars and expecting him to do all the work required thereon. From paper at the Boston Convention, 1898.

LETTERS AND HINTS FROM PRACTICAL MEN

Notes on the Standard Rules and Regulations as Reported by the A. S. R. A. Committee

II.

Schenectady Railway Co.,
Schenectady, N. Y., Feb. 18, 1899.

Editors Street Railway Journal:

In an article in the February number of the Street Railway Journal, the qualifications and limitations necessary for a set of "general" rules for street railway employees were outlined, with the intention of judging by them the set of "Standard Rules and Regulations" as submitted by the committee of the A. S. R. A. and published in the December Journal.

In this and succeeding articles this test will be made, and where the rules of the committee do not fulfil the conditions, criticism will be made, changes and amendments suggested and reasons given therefor.

Taking the qualifications and conditions as enumerated in the February Journal and submitting the report to them, we wish to know—

First—Are they all *rules?* Several of them are not, as a whole, and many of them are not in part. General Rules Nos. 1 and 2 are announcements regarding the rules, their place is on the title page or closely following. No. 7 is a notice to the employees of the policy of the employer in regard to promotion, etc. Its place is in an "Introduction" to the rules, or in a "General Notice." No. 8 is not a rule at all, it comes under the head of "unnecessary and axiomatic remarks." Any reasonable being knows that a wilful, repeated or inexcusable act of the kind therein specified should cause his dismissal from *any* position, and especially from a service that deals with the public as a common carrier, where the consequences of such acts are liable to be so serious to the employer. Of a similar character are the third paragraph and the last part of the fourth, under "Depot Masters." For what general reasons are the heads of departments hired except for "properly conducting" their part of the "company's business," looking after the "safety of the property intrusted to their care," and seeing that employees under them are "prompt and efficient in the discharge of their duties?" These are not the peculiar duties of a "depot master," they are the well-known and thoroughly understood principles of duty of *all* heads of departments or sections of departments. They are all the very axioms of duty, and to put such truisms in as rules is to insult the intelligence and common sense of the employee. General rule 15 and rule 13 for conductors and motormen are other similar cases, they contain the stereotyped phrases, "will be held responsible for the care and protection of the property of the company coming into his hands" and "will be held responsible for any damage caused by their neglect or carelessness." Of course they will be; *all* employees are; not only those of street railways, but those of "the butcher, the baker, the candlestick maker!" Care of the employer's property is a necessary qualification of *any* employee and cannot be too carefully fostered, but it must be done in other ways than by repetitions of bald-headed truisms. If it is really the intention or practice of the employer to penalize carelessness or negligence, such practice should be stated in positive terms under a "general notice" or should form one of the "general rules" and should read as follows:

"Any damage done to company or other property, or any loss or expense incurred by the company by reason of neglect or disobedience of these rules will be charged to the account of the employee or employees responsible for the damage, loss or expense, and the amount so charged up will be deducted from their ———." (Pay, deposit or bond, as the case may be.)

Rule 14 for inspectors is not a rule, it is very good advice and might be put into a note at the end of the inspector's rules, or into the "General Notice."

Under rule No. 3 for motormen the words, "and accidents can and must be avoided," and the paragraph following them are not only unnecessary remarks, but they are *not true*. The employer and the employees are both aware that by no amount of human foresight or care and by no use of appliances, can *all* accidents be avoided. Even the law—and coroner's juries—do not go that far; therefore, to make such an unqualified statement, and to put it in capitals, is to make the whole rule ridiculous instead of impressive, as a "safety rule" should be. These paragraphs should be cut out of the rules and only put in the "General Notice" in an amended and truthful form.

The first part of rule 1 for conductors is objectionable in many ways; its intent seems to be that even around the depot—away from passengers—profane and filthy language is not to be used, but the wording of this part is unhappy, as—by inference—it says that other employees may use such language around the depot and—as there is no other rule to the contrary—conductors may swear and use "improper language" in other places. Again, by placing such a rule under "Special Rules for Conductors" and nowhere else, it would be apt to give the impression that either the conductors were the only employees with foul mouths, or that they used the depot as the only available place in which to express their feelings! These remarks have no place in this rule or in this section of rules. If it is thought necessary to touch on this matter, it should be placed in the "General Rules" for all employees, and worded about as follows:

"They will—while on duty or about the premises of the company—*entirely abstain* from profane or indecent language and from improper or ungentlemanly conduct, and they will, in *all* cases, be polite and courteous in their dealings with one another and with everyone with whom they come in contact in the performance of their duties."

Rule No. 15 for conductors is mostly unnecessary remarks. The specific part of it in regard to "waste, etc." should be amplified and elaborated into a rule as will be shown further on, and the "good judgment" part entirely cut out. Good judgment is common sense applied to cases where experience or specific directions are lacking, and in a matter as important as the care of his car, specific directions—either by rule or by oral directions from his depot master or inspector—should *not* be lacking.

Rule 19 is of the same style—only worse. It should not reflect on the other employees by making the conductor the only person who—under the rules—is allowed to use his own judgment! It should be completed and made a "general rule" and should read:

"They (all employees) will—in the absence of officials to whom they may apply for advice, assistance or authority—exercise common sense and discretion in dealing with matters not provided for in the rules."

Finally—as regards their being rules—the first paragraph under "General Requirements"—in fact the whole of this section, and the three paragraphs under "Penalties" (following rule 23 for motormen) are not rules. As they stand, they are recommendations and suggestions by the committee to employ*ers*, and should be put into the report as such, or incorporated into the "General Notice," or put

into shape as rules. As they are placed they are out of place, especially the matter under "Penalties" (about which something will be said further along) and the location of which under "Special Rules for Motormen" might suggest that this generally excellent body of men were the black sheep of the flock!

By a difference of wording and arrangement most of the "General Requirements" would make excellent and necessary general rules. A uniform and generally known and understood set of "requirement rules" for certain employees would be a blessing to all who had the hiring of them. They would make a "standard," and as such would save much trouble with labor organizations, with nepotic directors and with politicians who had a "pull" and needy relations and friends, and they would save the labor of sorting out a lot of "dead-wood." These rules would use the word "must," they come under the "imperative case" spoken of, as they fix a standard. The raw material *must* come under rule and measure—afterward, when it is licked into shape, when it has been tested—flexibility may be allowed, but the "requirement" section of the rules should be absolutely positive.

Second—Are they "general" in the sense of being of universal application within a certain territory—in this instance the United States? Could any road in either Maine or Florida, California or New Jersey, single or double track, urban, suburban or interurban, high-speed or low-speed, big or little; could any one of these roads pick out from these rules a full quota of general rules (those not local) for its use, or for guidance in formulating a code of rules of its own? It is, of course, thoroughly understood that the most complete and perfect set of general rules could not be used as a whole by every road, nor hardly by any one road—snow storm rules would be slightly out of place in Southern California or Florida—but in such a complete set of rules any and every rule not caused by peculiarly local conditions should be found complete, or its spirit and principle should be indicated.

On the ground of passing away, the committee has excluded rules "especially applicable to street railways operated by horse or cable power," and it has also—whether on the same grounds or not, is not stated—excluded rules especially applicable to single track roads, to roads operated by open or closed conduits, by third rail, by storage batteries, compressed air or kinetic motors; while it has included rules especially applicable to roads operated by overhead trolley and on double track. These rules are not general therefore in the sense of being universal, and cannot be so until they can be used as general rules by every street railway in the United States, no matter what its motive power or the character of its track, traffic or equipment. If such cannot be done without bringing in rules especially applicable to some one system of motive power or to some special method of using it, then it would be better to leave out of *these* rules those that relate to such subjects except as they may be applicable to *any* motive power or method of using it, and to put the special rules for each system under separate heads. It is conceded at this present time that the overhead, under-running trolley is largely in the majority, but with the advances made in other methods and motive powers, it is not safe to say that such majority may continue for any great length of time, and it would therefore be wiser in the beginning to avoid in any general set of rules those applying to any special and transitory method, or apparatus.

Third—Are they "general" in the sense of not being local or individual? This is best answered by asking a few questions. Is it general, or, is there a reason, good and sufficient enough to make it general, to exact $10 for a badge or $20 for a uniform? Or to use one tap of the signal bell as a signal for the motorman to stop at the next crossing or trolley station? Or to call a rheostat or resistance coil a "diverter"—a name used by one special manufacturer? Or to charge *5 cents* for every adult passenger or *3 cents* for every child between the ages of three and twelve? Or to permit only five policemen, firemen or employees on a car at the same time? Or to allow smoking on the *three* rear seats of open cars? Or to make an employee send an excuse by *special messenger* if he is absent through sickness? Yet all of these, and some others not noted, are specified in the rules, and all of them are local and individual. If the idea has been in each case to suggest a principle, it should have been done by giving the skeleton of the rule and leaving the specific name, number and amount to be filled by each road according to its local conditions. For instance, it is a wise thing and one of general use to formulate a general rule limiting the number of "dead-heads" that should ordinarily be carried on any one car at one time, but it reduces a general rule to a local one to make such a number fixed and specific, as local conditions would govern that point absolutely.

These rules are stated in the report as being for conductors and motormen, but the committee have included in the report those for "depot masters," "receivers" and "inspectors." Leaving out the receivers, whose duties are dismissed with a curt paragraph, the division of the officials immediately in authority over the conductors and motormen into "depot masters" and "inspectors," and the defining of their duties as such is an arbitrary and local action and not a general one. It is true that there must be some one in direct authority over the conductors and motormen when they are *not* on the cars, and there must also be some one in like authority when they *are* on the cars, and that on a road of any size at all, these officials cannot be one and the same man. It may also be true that the division of these officials into depot masters and inspectors and the arrangement and division of their duties as suggested by the committee is a correct one for certain roads, but it can never be a general one and certainly could never be made a standard one, even within a State, as local conditions would influence the duties and division of duties of these officials so greatly as to prevent any such arrangement as is suggested by the committee being made general even by roads of similar size or number of employees. As a matter of fact, the office of "inspector" is quite different on different roads. Originally they were what their name implies, "inspectors" of men, cars or motive power, but, as street railways have enlarged both in size and aims their duties have been increased, broadened and changed until they are more "supervisors" than "inspectors" on some roads. Even on the same road the duties and authority of one so-called inspector will be totally different from another one bearing the self-same official title. It is, therefore, to be easily seen that any attempt to generalize the title or to divide and specialize the duties of the officials directly in authority over the conductors and motormen, would be at this time an impossible task.

Fourth—Are they comprehensive? Do they cover every point in regard to the general duties of these employees in relation to their superior officers and officials, in relation to one another, to the property they are intrusted with and to the public? On some of these points they are fairly full and complete, on others they are not, and on others they are almost lacking. This may seem a strong statement but—as this head will be more fully treated under No. 11 ("Classification and Arrangement")—a single instance will be given to prove the statement. The property intrusted to the care of the conductor—the car itself—is a valuable

one and the proper care of it by him will be an important item in the maintenance account. The neatness and cleanliness of the inside of the car, the proper adjustment of the ventilation, temperature and lighting, will all tend to increase the comfort of the passengers and, consequently, their satisfaction with the service. Therefore, on both these points, the rules should instruct him and guide him to the fullest extent. In relation to these duties, the rules as reported by the committee are conspicuous by their absence, as they consist of the last sentence of rule 28 for conductors and motormen, and Nos. 15, 25, 31 and 33 for conductors, in all, a matter of a dozen lines on this subject, and of this dozen lines nearly a third are *not* instructions. As a matter of comparison, the following in relation to this point is given as a suggestion of a more complete rule:

SPECIAL RULES FOR CONDUCTORS IN RELATION TO CAR

Rule No. —. CARE OF CAR.—As the conductor will be held solely responsible for the condition of car while in his charge, he will, when taking it from depot, from an inspector or from another conductor, make certain that it is clean; that no parts, such as windows, shades or seats, are broken; that the signal bells and register work properly; that oil lamps (if used) are trimmed and in order; that .... spare incandescent lamps (if used) are in their receptacles, and that all .... (implements or tools used by conductor or in his charge) are in good order and in their proper place. In case the car is dirty or any apparatus, tools or appliances, or parts of car are missing, broken or defective he will at once note the fact on ..... (form or portion of form for that purpose).

He will see that car is properly and thoroughly swept and dusted at least ..... (once, twice or thrice) during his swing or run, or oftener if the weather necessitates it.

(Or) He will thoroughly sweep the car and platform floors and the steps when on stand.

He will take care to adjust the ventilation of the car according to the weather. In closed cars the doors must be kept closed in cold weather as much as possible, and ventilation given when needed by the ventilating sash in roof. In hot, sunny weather the blinds (or shades) should be closed on sunny side of car.

He will not allow the blinds and windows to drop when handling them, but will raise or lower them carefully; he will not slam the doors, and will turn the signs and all reversing seats carefully.

(If used) He will keep the oil lamps turned low when first lighted; will not allow them to smoke, and will relight them AT ONCE if they become extinguished.

He will keep all gloves, overshoes, rubber coats, waste, etc., in their proper lockers, and NO WHERE ELSE.

He will not allow any person to put their feet or dirty articles or bundles on the seats; to put their feet on the dasher or the woodwork of the car; to spit on the floor or platforms or behind the seats; to scratch matches or write on the car; to throw paper, nutshells or other rubbish behind the window-blinds or on the floor, or to in any way UNNECESSARILY damage, disfigure or dirty the car.

He will allow no advertisements, notices, show-cards or circulars to be placed in or on the car without direct order or written permission from his ..... (proper officer for this purpose).

He will not allow newsboys, peddlers or solicitors of any kind to ply their vocation on his car.

Finally: He will, in all other ways, take good care of his car, and do everything possible to preserve it and to keep it neat and clean, and make it comfortable and attractive to passengers.

Fifth—Are they clear and explicit in language? General rule No. 5 says: "No one will be excused for violation of the rules even though not included in those applicable to his department." What is "not included," the employee or the rules? It can be read either way equally well. What is evidently meant is "No employee will be excused for violation of a rule even though such rule is not directly applicable to him or his department." Of the reasonableness of this, something will be said further along.

Rule No. 6, following above, has, in capital letters, "Ignorance is no excuse for neglect of duty." This is probably intended as a paraphrase of the legal maxim, "Ignorance of the law excuseth no man," but it goes wide of its mark in its present form, for ignorance by itself would be an excuse. As nearly as can be guessed from the preceding part of the rule, the intention has been to state that "ignorance of the true meaning of a rule or order will not be received as an excuse for the neglect of it," but that would be highly unreasonable and unjust and would be bettered but little by placing the word "wilful" before "ignorance." As a matter of fact, any and every ordinary and general rule or order should be so plain and explicit that any employee of average common sense and in the class or group of employees for which the rule is intended, should be able to rightly comprehend it. If a rule or order is one that deals with technical or special matters which might be beyond the understanding of the employee, or of a new employee, care should be taken that such rule or order should be diagrammatically or orally or practically explained before being enforced. Given an ordinary or general rule as carefully, plainly and clearly expressed as possible, and the employee who cannot or will not understand it without oral explanation, is not, as a rule, the proper employee to work under that rule.

Paragraph 17, under "Depot Masters," says: "They must arrange to sand the rail when necessary." Rule 16 for inspectors, says: "They should give special attention to sanding the track on hills," etc. In both cases, being officials or in authority, it means that they are to have it done, and the rules should read: "They must arrange to have the rail sanded when necessary" and "they should give special attention to the sanding of the track on hills," etc. Of course, it is understood that in an emergency case, there being no one else to do it, a depot master or inspector would sand the rail himself, but that is not the intent of the rule.

General rule No. 9 for conductors and motormen says: "Under no circumstances must a conductor and motorman be away from a car at the same time unless properly relieved." What is meant is, "Under no circumstances must *both* motorman and conductor be away from *a* car, unless properly relieved."

Rule No. 12 says: "The official badge must never be worn by anyone except to whom it is issued." This was probably intended to have the words "the employee" inserted between "except" and "to." It is even then not complete, the rule in regard to badges should be: "The official badge must be worn in plain sight so as to be readily seen and read at all times. Under no circumstances will employees exchange badges with one another, nor will they lend them to *any*one for *any* purpose. The official badge must never be worn by anyone except the employee to whom it is issued."

Under rule 5 for inspectors, they are required to "keep themselves informed of all instructions issued by the officials of the company and see that they are complied with." This is a "big order" for an "inspector,"—in the first place, to ask them to "keep themselves informed," in the next place, to keep informed "of all instructions issued by officials of the company," and, lastly, to "see that they are complied with!" If this were really the intent of the rule an inspector's life would be like that of the policemen in the "Pirates of Penzance," "*not* a happy one!" As a matter of fact, no official or minor official should have to "keep informed" as to any orders which affect him or his department. Such orders or instructions should reach him directly in writing or printing, should be posted in a place that he is expected to examine regularly for them, or, in case of emergency or of trivial matters, may be given verbally. In no case should he be expected to hunt up orders or instructions, nor should he be expected to be familiar with or responsible for the "compliance with" any orders

or instructions not affecting himself, his department or the employees under his charge. The rule should read: "They will make frequent examination of the bulletin board for orders or instructions affecting themselves, their department or the employees under their authority, they will make themselves fully conversant with them and see that they are complied with."

Under rule 13 for motormen the words, "passing men on the street," should read "passing men *at work* on the street." Under rule 9 for same the word "junction" in second line should be "curve," and the word "the" before "junction" in the third line should be "a."

Some of these may seem like trivial items to criticise and it may be that some of them—together with a lot more which have been criticised—may be due to the "intelligent compositor" or his able coadjutor, the typewriter, but there are many of these items that are evidently not the handiwork of these two, and are therefore subject to the criticism that in matters where a word or sentence misplaced, omitted or wrongly used may alter cases of vital importance and lead to very harmful results, there should be nothing used but the clearest and most explicit language, brevity must be sacrificed to perspecuity in rules, especially in "safety rules." H. S. Cooper.

(*To be Continued.*)

Method of Keeping Accounts

Baltimore, January 23, 1899.

Editors Street Railway Journal:

I have carefully considered the article on "An Ideal System of Street Railway Accounts," in your January issue, and it gives me pleasure to say that it seems to me thorough. Of course, its use involves much work, but without that work some detailed showing would be necessarily omitted. A simple system would give results but omit much desirable analysis. De Courcy W. Thom.

The local conditions should govern the type of double truck used, the bolster type in most cases being preferable for long cars on high speed, suburban service, while for city service, where heavy grades and quick starts demand maximum traction, and short curves make it necessary for the wheel to turn under the sill, the bicycle type must necessarily be used. From paper at the Boston Convention, 1898.

Power Station Records

Trenton Street Railway Co.,
Trenton, N. J., Feb. 17, 1899.

Editors Street Railway Journal:

I enclose the report of our power station for the year ending Dec. 31, 1898. The low cost in fuel consumption in April and October was due to our taking account of stock of coal on hand those months. The cost of power includes the expense of lighting our park and of heating and lighting our cars.

In our station we have one 100 h.p. and two 400 h.p. Watts-Campbell tandem compound condensing engines; six 100 h.p. return tubular boilers; four Short 100 kw. generators, and one G. E. 750 kw. generator. The generators are belted with the engines. Our boiler pressure is 100 lbs. Henry C. Moore, President.

Statement of the Cost of Operation of the Trenton Street Railway Company for the Year 1898.

A Formula for Train Resistance

Massachusetts Institute of Technology,
Department of Engineering.
Boston, Mass., Feb. 2, 1899.

Editors Street Railway Journal:

I should like to know more with reference to the original data of Mr. Lundie's experiments before I can make up my mind regarding his formula. I am inclined to agree with the remarks from "Locomotive Engineering," which you quote at the beginning of your article. Trains differ very much as regards every element in the problem. With reference to Mr. Lundie's method, of course you are familiar with the tests which were made in connection with the Burlington brake tests, by which trains were allowed to run until they came to a stop, so that Mr. Lundie's work is not new in this respect. I do not think that it is shown very conclusively that these lines *ought* to "intercept each other with surprising accuracy at a single point," since the lines as drawn are plotted from the equation and must, of course, meet at this point. I think the form of Lundie's equation is better than that of Clark's, although S should not appear to the first power or to the second power, but to some intermediate power. The same result might be attained with two terms, one with S and one with S^2. Cannot you publish an article giving all the details of Lundie's experiments, or does he wish to keep them for publication

in some original paper? They would, no doubt, be of much interest, and I should be glad to see them.

Geo. F. Swain, Professor of Civil Engineering.

The Chicago City Railway Company,
Electrical and Engineering Departments.
Chicago, Ill., Feb. 3, 1899.

Editors Street Railway Journal:

I am much interested in Mr. Lundie's formula for train resistance. The figures given by him are much lower than anything we are able to get in street railway practice owing to the difference in the conditions, as you have mentioned. We have in street railway work a rail almost buried in dirt, especially in this city, and you can readily appreciate that there is double, and more, the track resistance on such a rail than there is on a steam railroad rail lying high and dry; and I quite agree with you when you say that it is probable that no formula can be devised for street railway work where the conditions vary so largely.

I remember a few years ago making a test in order to determine when it is time to replace a badly worn rail, and the wide range in differences in draw bar pull per ton may be observed in the following table:

	Average Speed in Miles Per Hour.	Total Weight of Car Tons.	Draw Bar Pull Per Ton.
1. On badly worn rail...	12.9	4 1/3	43.8 lbs.
2. On badly worn rail...	10.	4 1/3	40. lbs.
3. On nearly new rail....	12.	4 1/3	26. lbs.
4. On nearly new rail....	11.4	4 1/3	30. lbs.
5. On badly worn rail...	8.6	4 1/3	37.5 lbs.
6. On nearly new rail....	8.8	4 1/3	24.2 lbs.

The rail was dry and comparatively clean, and the resistance small. In test No. 5, the time consumed in starting and stopping was eight minutes and forty seconds; and in test No. 6, nine minutes and forty seconds. The rate of speed attained in these two tests includes the time consumed in making stops and starts. With "badly worn rail" the flanges of wheels were, in many instances, running on the tram of the rail. In noting the difference in draw bar pull per ton with a new rail and an old one, it can readily be appreciated that it is false economy to try to operate a street rail after it becomes badly worn.

I doubt if it is possible to adopt any given formula; that is, for practical use, for train resistance, no matter how carefully determined, when, in the majority of cases, the joints of steam railroad rails are very poor and irregular in the matter of alignment, and this difference alone would, in my opinion, vary the results very materially, to say nothing of the variations which would be caused by "spongy" sub-grades, etc. As I understand it, Mr. Lundie made all of the observations, from which he worked out his formula, on the Alley "L" or South Side Elevated Railway. He had, of course, in that track, ideal conditions existing in the way of a solid road-bed and well aligned and rigid joints and rails such as are rarely found with surface steam railways.

Mr. Lundie certainly deserves great credit for his efforts and their results in working out this formula, and the method he used gives an accuracy which has not heretofore been obtained.

G. W. Knox,
Electrical Engineer.

New York, Feb. 14, 1899.

Editors Street Railway Journal:

While I have a very limited knowledge of the subject, I would say on general principles, that the formula which does not contain the square of the speed in one of the terms, cannot be true for widely different values. But if, as you say, the practical results within certain limits agree with the values found according to Mr. Lundie's formula, his work will not be the less welcome to engineers.

Nikola Tesla.

Sibley College, Cornell University.
Ithaca, N. Y., Feb. 13, 1899.

Editors Street Railway Journal:

I am very much interested in the question of train resistance, and am entirely convinced that some of the recently proposed formulæ that did not take into consideration a variation of the traction coefficient with the speed were wrong, but did not find it convenient to take up the matter at that time. A comparison of actual acceleration curves and those deduced from other formulæ would indicate that Mr. Lundie's formula is more generally applicable than any yet proposed. S. B. Fortenbaugh.

The Lake Shore & Michigan Southern Railway Co.,
Engineers Department.
Toledo, Ohio, Feb. 15, 1899.

Editors Street Railway Journal:

We have never made any scientific train resistance tests, so far as I know. Mr. Lundie's formula is certainly very interesting. Such an empirical formula, if carefully made from a sufficiently large number of observations, ought to have good results within those limits, and under conditions similar to those under which the observations were made. But it is difficult to pick out the value of the different causes which have contributed to make up the numerical factors of such a formula, or the effect upon these causes when the conditions under which they operate may be changed, so no one can say whether these numerical factors are correct outside the limits of actual observation. Fortunately, however, most cases will come near enough within these limits, and consequently all such formulæ have a value. I hope this one will have a large one.

Samuel Rockwell, Engineer M. S. Division.

University of Wisconsin,
College of Mechanics and Engineering,
Madison, Wis., Feb. 2, 1899.

Editors Street Railway Journal:

Mr. Lundie's formula appears to agree unusually well with experimentally deduced results, and it may rightly be looked upon as a decided improvement upon the older formulæ. The insertion of the train weight as a variable in the formula follows the line of argument set forth, for instance, by Searles, when he premises in his field book that a formula of the kind here considered "must include at least the velocity and weight of the train and engine;" and it is a substantial service to engineering to put a formula of this nature into useful shape. Mr. Lundie is to be congratulated upon deriving a formula of so apparently wide application, but no fixed formula can be fitted to the widely varying conditions met in street car (surface) traction as it now exists. D. C. Jackson, C. E.

From the information before us, we feel sure that we can safely assume twenty-four years as the life of a creosoted tie, and with this assumption we will determine the cost of keeping the different kinds of ties under sections of track for twenty-four years. Creosoted ties will cost 24 cents per lineal foot of track; therefore, 60 cents (36 and 24) will represent the cost of labor and ties per lineal foot in rebuilding. Principal and interest on 60 at 6 per cent for twenty-four years, $1.46—which is the actual cost per lineal foot of keeping ties under this track for twenty-four years.—From paper read at the Montreal Convention, in 1895.

The Next Convention.

The eighteenth annual meeting of the American Street Railway Association and the third annual meeting of the Street Railway Accountants' Association of America will be held in Chicago, Ill., Oct. 17, 18, 19 and 20, 1899, at "Tattersall's," State and Sixteenth Streets. This building contains 50,000 sq. ft. of floor space, without a post or obstruction of any kind.

Friday, Oct. 20, has been set as a day for an examination of the exhibits. No session of the association will be held, so that all may have plenty of time to view the exhibits. The association will especially request that managers have their heads of departments present on that day.

President Charles S. Sergeant, of Boston, Secretary and Treasurer T. C. Penington, of Chicago; Walton H. Holmes, of Kansas City; Albion E. Lang, of Toledo; George A. Yuille, of Chicago; Frank G. Jones, of Memphis; John I. Beggs, of Milwaukee, and Ira A. McCormack, of New York, members of the executive committee of the American Street Railway Association, met in Chicago, Feb. 6 and 7, and completed all the preliminary arrangements for the convention. The hall is well suited to the purposes of the exhibit, having a clear floor space, without columns, of 50,000 sq. ft. The meeting rooms of both associations will be under the same roof as the exhibit, with ample retiring and committee rooms. The last day of the convention will be set apart for the systematic and careful inspection of the exhibits by the delegates, a fact which will be appreciated by all exhibitors. The banquet will be given on the night of the last day of the convention, at which the installation of the newly elected officers will take place. The committee resolved to make unusual efforts to secure the attendance of representatives of the mechanical, operating and auditing departments, which will make the convention of great practical value to those branches of the service; the attendance having been largely confined to delegates from the administrative departments. The hall will be well lighted and heated; the light during the hours of the day leaving nothing to be desired. All the exhibits will be on the same floor, and there will be little choice as to location. All electric power necessary will be furnished. The hall is within 300 ft. of the steam railroad tracks, and a special siding will be laid to the rear door of the hall, so as to bring the heavy exhibits direct to the hall.

The following subjects were selected, upon which papers are to be read at the meeting: "Maintenance of Car Equipment;" "The Modern Street Railway Shop; Its Design, Machinery and Shop Practice;" "Train Service, and Its Practical Application;" "Investment in Street Railways; How Can They Be Made Secure and Remunerative?" "Construction and Maintenance of Railway Track."

The annual banquet will be held Friday evening, when the officers elected will be installed.

The headquarters of the association will be at the Auditorium Annex. The Auditorium is across the street and is under the same management. Chicago is noted for its good hotels, so no trouble will be experienced in securing good accommodations. The rates charged at the hotels mentioned are: Auditorium, American plan, $5 per day each person; Auditorium Annex, European plan, $2 to $4 per day.

All of the leading hotels in Chicago are within a radius of one-half a mile. They include the Victoria, Wellington, Great Northern, Grand Pacific, Palmer, Tremont, Sherman and Clifton, and all are within ten-minutes' ride of the hall.

The executive committee advises all who desire rooms to apply at once. The rooms at the Auditorium will not be assigned until Mar. 15, and will be assigned in the order in which applications are received.

Railroad rates will, in all probability, be as before—one and one-third fare for the round trip, due notice of which will be mailed the members of the association in time.

The representatives of the association who reside in Chicago intend to make the visit of all a pleasant and profitable one, so that no one will regret attending this convention.

The following organization has been effected for the entertainment of the delegates and other attendants:

GENERAL COMMITTEE

Chairman, M. K. Bowen, president, Chicago City Railway.
Secretary and treasurer, Geo. E. Yuille, second vice-president, West Chicago Street Railroad.
J. M. Roach, vice-president and general manager, North & West Chicago Street Railroad Company.
Geo. C. Nagle, superintendent, Chicago City Railway Company.
H. M. Sloan, general manager, Calumet Electric Street Railway Company.
H. H. Windsor, Editor "Street Railway Review."
F. L. Fuller, general superintendent, West Chicago Street Railroad Company.
Jas. R. Chapman, general manager, electrical department, North & West Chicago Street Railroad companies.

ENTERTAINMENT COMMITTEE

J. M. Roach, chairman, vice-president and general manager, North & West Chicago Street Railroad Co.
T. M. Henderson, superintendent, N. C. Street Railroad Company.
A. S. Littlefield, railroad contractor.
Geo. C. Bailey, John A. Roebling's Sons Company, Chicago.
Harry Keegan, assistant superintendent, N. C. Street Railroad Company.
Frank R. Green, secretary, Chicago City Railway Company.
Geo. A. Yuille, second vice-president, W. C. Street Railroad Company.

EXHIBIT COMMITTEE

Jas. R. Chapman, chairman, general manager, electrical department, North and West Chicago Street Railroad companies.
C. E. Moore, master mechanic, Chicago City Railway Company.
John Miller, master mechanic, North Chicago Street Railroad Company.
F. T. C. Brydges, master mechanic, West Chicago Street Railroad Company.
A. C. Heidlberg, assistant superintendent, Chicago City Railway Company.
Geo. W. Knox, chief electrician, Chicago City Railway Company.
W. F. Carr, superintendent, electric and track dept., W. C. St. R. R. Co.
W. A. Harding, master mechanic, Calumet Electric Street Railway Company.
N. C. Noe, engineer, General Electric Company.

TRANSPORTATION COMMITTEE

F. L. Fuller, chairman, general superintendent, W. C. St. R. R. Co.
W. Worth Bean, president and general manager, St. Joseph & Benton Harbor Electric Railway & Light Company, St. Joseph, Mich.
Wm. Walmsley, superintendent, South Chicago City Railway Company.
Wm. J. Cooke, McGuire Manufacturing Company.
T. D. Miles, with West Chicago Street Railroad Company.
J. M. Atkinson, of J. M. Atkinson & Co., of Chicago.
John O'Keefe, with Chicago City Railway Company.

PUBLICITY AND INFORMATION

H. H. Windsor, chairman, Editor "Street Railway Review."
C. S. McMahan, Western manager, STREET RAILWAY JOURNAL.
D. B. Dean, Terre Haute Car Manufacturing Company, Terre Haute, Ind.
J. A. Hanna, Peckham Truck Company, Chicago.
C. J. Riley, chief engineer, Chicago City Railway.
John O'Keefe, Chicago City Railway Company.

HALLS AND HOTELS

Geo. O. Nagle, chairman, superintendent, Chicago City Railway Company.
A. S. Littlefield, railroad contractor.
T. M. Henderson, superintendent, North Chicago Street Railroad Company.
Maurice Coster, Westinghouse Electric & Manufacturing Company.
T. C. Penington, treasurer, Chicago City Railway Company.

BANQUET COMMITTEE

M. L. Bowen, chairman, president, Chicago City Railway Company.
D. G. Hamilton, Chicago City Railway Company.
M. B. Starring, assistant general counsel, Chicago City Railway Company.
B. E. Sunny, General Electric Company.
H. H. Windsor, Editor "Street Railway Review."
C. S. McMahon, Western manager STREET RAILWAY JOURNAL.
Geo. C. Bailey, John A. Roebling's Sons Company, Chicago.

LADIES' COMMITTEE.

H. M. Sloan, chairman, general manager, Calumet Electric St. Ry. Co.
Theo. P. Bailey, General Electric Company.
Joseph Leiter, Chicago City Railway Company.
Frank R. Green, secretary, Chicago City Railway Company.
F. L. Fuller, general superintendent, West Chicago Street Railroad Company.
M. K. Bowen, president, Chicago City Railway Company.
C. K. Knickerbocker, Griffin Wheel Company, Chicago.
L. S. Owsley, secretary and treasurer, North Chicago Street Railroad Co.
J. Chas. Moore, secretary and treasurer, North Chicago Street Railroad Co.

FINANCE COMMITTEE

Geo. A. Yuille, chairman, second vice-president, West Chicago St. R. R. Co.
C. R. Penington, with Chicago City Railway Company.
J. Chas. Moore, secretary and treasurer, North Chicago Street Railroad Co.
W. S. Bell, assistant secretary and treasurer, West Chicago Street R. R. Co.
H. B. White, secretary and treasurer, Calumet Electric Street Ry. Co.

Mr. John M. Roach, representing the local street railway interests, entertained the committee during their stay in Chicago. On Monday night, at 6 o'clock, there was a dinner at the Union Club, at which the following gentlemen were present: F. L. Fuller, William Walmsley, T. A. Henderson, Albion E. Lang, John I. Beggs, H. M. Sloan, John M. Roach, Frank R. Greene, T. E. Crossman, H. H. Windsor, Ira A. McCormack, W. Worth Bean, A. L. Plimpton, H. F. Grant, Walton H. Holmes, T. C. Penington, Chas. S. Sergeant, Frank G. Jones, George A. Yuille, George O. Nagle and J. R. Chapman. After the dinner the party attended the performance at Powers' Theatre. On Tuesday afternoon, upon the conclusion of the work of the committee, a visit was made to the office of the North Chicago Street Railway Company, where President Yerkes received the gentlemen. Subsequently a visit was made to the Western Avenue power station and other points of interest connected with the company.

The Brown Hoisting & Conveying Machine Company, of New York and Cleveland, Ohio, has just been awarded a contract by the Navy Department for coal handling machinery for the coaling station at Mare Island Navy Yard, California. This is the sixth coaling station for the United States navy to be equipped with the Brown Company's machinery, and constitutes all the stations so far awarded. The Brown Hoisting & Conveying Machine Company has also been awarded a contract for a 100-ton steel floating crane for the Brooklyn Navy Yard. This crane will weigh over 1000 tons.

STREET RAILWAY JOURNAL

MARCH, 1899

PUBLISHED MONTHLY BY

THE STREET RAILWAY PUBLISHING COMPANY

MAIN OFFICE:
NEW YORK, HAVEMEYER BUILDING, 26 CORTLANDT STREET.

BRANCH OFFICES:

Subscriptions payable always in advance, by check (preferred), money order or postal note, to order of C. E. WHITTLESEY, Treasurer.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Havemeyer Building, 26 Cortlandt St., New York.

The power stations of practically all of the large street railway systems of this country, and of most of the smaller ones, have been in operation now for at least two years, and many of them for a considerably longer period. During this time many improvements in the economical generation of current have been made, so that the question as to what extent reconstruction should be engaged in is an important one. In many cases the need is intensified by a radical change in location of the "center of gravity," or center of the distribution circuit, caused by the construction of new lines or consolidation with old ones, which has often put the existing power station far away from the most economical point for distribution. Whether, when the station becomes thus antiquated, either in equipment or location, it is better to reconstruct or to continue the old equipment is a special problem of each situation. The best way is to carefully calculate the cost of operation in each case, including that of depreciation and loss of power, and compare the possible saving with the interest on the cost of new investment required. The operating expenses of modern power-house machinery are now so well known to engineers that, if the expenses of the existing plan have been carefully kept, this comparison ought not to be a difficult one. In some cases the economy will be considerable, as in that of the Consolidated Traction Company of Pittsburgh, mentioned elsewhere, where it was found a saving in cost of generating power of 56 per cent could be made by the substitution of one modern station for several older ones.

The advantages of the "loop" idea in terminal arrangements, long well known and appreciated in street railroad practices, are about to be demonstrated in steam railroad suburban service on a large scale. Hitherto the loop has not been used to any extent, if at all, in railroad city termini, because of the impossibility of getting the necessarily large radii of curvature within the limits of the terminal station, but in the enormous South Terminal station, just completed in Boston—the largest station in the world—sufficient room is found to use loop, instead of stub tracks, for suburban trains, and, as a consequence, the ultimate train handling capacity of the entire station is more than 2000 trains per day, of which the twenty-four stub tracks will handle 750 trains, while the two-track route will handle 1250 or more. This is a quite unprecedented capacity. The effect of this terminal arrangement on the traffic conditions in Eastern Massachusetts is far reaching—much more so than might at first appear on the surface, for there is now no doubt that it is the intention of the two great railroad systems which will use this terminus to run their suburban trains by electricity, and to give a frequent service at regular short-time intervals. With the advantage which comes with ownership of right of way and with possibility of high speeds, based upon the complete abolition of grade crossings, which is now rapidly going on in Massachusetts under compulsory legislation, it is much to be feared—or hoped, according to the point of view,—that the keenest kind of competition will come between the railroad and street railway services in the same territory, and the result will quite probably be the usual one, namely, that the public as a whole will ride much more freely and frequently than ever before, the street railways will get the short-distance travel, and the railroads the longer hauls.

The consolidation of properties in the same lines of business seems to be the order of the day, not only in industrial enterprises, but also in those engaged in transportation. The economies obtained in consolidating steam railroad properties have attracted capitalists interested in street railway companies, and press dispatches announcing the union of interests in some new city have been almost a matter of daily occurrence during the last two months. Among the most important events of this kind which have been consummated or announced during

the last month are the street railways around Buffalo, in Jersey City, Baltimore, Lexington, Ky., and the two principal railway systems of Brooklyn, while there are rumors of important consolidations in other cities, including Washington and New York City. While a large system cannot receive the same personal oversight from the acting manager as a small one, there is such a large possibility for saving in many directions that these usually far more than counterbalance the few economical drawbacks, and this is especially true in electric railway systems, where the replacing of several power stations by a single large one is an obvious economy of magnitude. A street railway system of a city, like its water, gas and telephone systems, is a natural monopoly, and is recognized as such by all students of political science, independent of ideas which they may hold as to whether such a monopoly should be owned and operated by the municipality or by a private corporation. It is, therefore, not improbable to expect the final union in most cities of certainly the competing street railway lines. It has been a noticeable fact that in such cases the public has been directly benefited by the pooling of interests in this way. As a usual thing, more transfers are given by the consolidated system than by the individual companies, a result which amounts to a reduction in fare. We do not anticipate, however, that combinations of this kind will materially lessen for any length of time the total number of electric railway companies in any particular section or in the entire country. The consolidations are usually made by the help of outside capital, which necessarily releases a considerable amount of money belonging to those owners whose properties have become absorbed. These persons, whose life has been spent in railroading, will naturally tend to remain in that field, and we think in most cases will turn to interurban electric railroading, which is as yet practically undeveloped, for an investment of their capital. We have referred in previous issues to the possibilities of this field, and to the fact that many of those who have previously made a success with street railway properties are now paying considerable attention to its development. The proposition, taken as a whole, is an exceedingly attractive one, especially since the improvements in three-phase machinery, which have made the cheap distribution of power over long distances an easy task.

The blizzard of Feb. 13 severely tested the capabilities of all the electric railways in the Eastern States in keeping their tracks clear of the snow and cars running. The storm was admitted by all to have been the most severe of any experienced since the famous blizzard of 1888, and it differed from that in being more general and in being accompanied by a low temperature, which added greatly to the inconveniences of the men in removing the snow from the tracks. All of the cities on the Atlantic seaboard, from Portland as far south as Washington, and even Richmond, were practically snowed in for several days, and traffic on most of the steam railroads in this section was brought to a standstill. As may be expected, the street railways were also affected most seriously. Being the furthest north of any of the large cities on the coast, Boston probably suffered more than any city, but in spite of this fact the Boston Elevated Railway Company had clear on Tuesday, Feb. 14, 320 of its 325 miles of electric track. The railway company in Boston has to cart away the snow which it clears from its tracks, and a good idea of the immense facilities which this company has for removing snow is shown by the fact that it had 175 snowplows in use on Monday night, together with 400 sleds and carts of its own for removing snow, with 600 others engaged for the purpose. According to General Bancroft, it was a test in which as much pluck and endurance were required to win as were ever seen in a football game, but the record made forms an excellent commentary upon the vigilance of the officials and men, and the foresight of the company in being prepared for emergencies of this kind. In New York the underground system received its third severe winter test. The new equipment of plows, which were purchased the first part of the winter, came into good use, and, although the traffic on the electric lines was discontinued for nearly twenty-four hours, the company did not suffer any more in this respect than the neighboring trolley lines. The trouble, as stated by Mr. Vreeland, president of the Metropolitan Street Railway Company, was due to track causes, and not to any interference with the electrical part of the equipment. The snow was light and dry and the wind blew it upon the tracks in drifts immediately after the passage of a plow or sweeper, so that the wheels of the electric cars could not obtain traction. It is interesting to note in this connection that the cable cars on Broadway, which do not depend upon the contact between the wheels and the rails for their ability to move, made a showing much better than the electric lines, and for this comparative immunity to snow which the cable system possesses it should receive due credit. Philadelphia, like the other cities, suffered a more or less complete blockade, but with the aid of some rotary snowplows recently secured and a large number of ordinary plows and sweepers the company succeeded in keeping some of its lines in continuous operation. Washington also suffered severely by the storm, but by constant and energetic work the tracks were kept comparatively clear and cars running. It is a remarkable fact that comparatively little damage is reported from the breakage of wires during the storm, even of those of telegraph and telephone companies, which, falling on a railway wire, often create as much, or more, trouble than the breakage of the trolley wire itself. Absence of trouble of this kind is attributed to the intense cold which prevailed, and to the consequent dry condition of the snow, which, as a result, did not remain on the wires. The past season has been remarkably prolific of heavy storms, and if coming seasons are to be as severe in this respect, the snow-fighting equipment of an electric railway company in our Northern cities will necessarily have to be as complete and elaborate as that of a steam railroad company. As a matter of fact, however, the average fall will be considerably below that which we have experienced during the present winter. Snowstorms are expensive, both in actual outlay and in the diminished traffic which results from them, and their expense to a street railway company soon runs into a large sum.

A good example of the way in which unreasonable prejudice is excited against electric railway companies by false and misleading statements was furnished last month by a circular issued by the National Board of Fire Underwriters upon the subject of electrolysis of water mains by

the electric railway current. Strange as it may seem, this report was afterward printed without comment or criticism by one of the best-known engineering papers of New York City, and was there credited to the engineer of the National Board of Fire Underwriters, although we understand that the author of the report does not occupy that position. The subject of the report, which was made by Fremont Wilson, was the bursting of a 4-ft. water main in Brooklyn, caused, it was alleged, by the effect of the return current on the pipe, and some idea of the writer's qualifications to pass judgment upon the subject is shown by the following extract:

> Intelligent expert engineers have proved beyond peradventure that 1.5 volts difference in potential between the water pipe and rail is dangerous; and here we have a railroad company deliberately transmitting an enormous current at a voltage anywhere from 250 to 400. If they were simply transmitting a current with a difference of potential of 15 or 20 volts, enough facts have been presented to prove that this amount of voltage carries with it a current that would, of necessity, under the natural laws, cause enormous destruction. And in proof of this, permit me to call your attention to another exhibit and complete report recently published by the trustees of the Dayton, Ohio, waterworks. I will quote from that report for your information: "At 4.5 volts it has been shown that 6-in. pipe can certainly become useless in five years." Query: What is now the condition of the 6-in. water pipes in Brooklyn, if what the employee has said is true, that a 6-in. pipe has been used as a return feeder with from 200 to 300 volts pressure upon it?

This is utter nonsense, from an engineering standpoint. The arguments as to the danger to the public sound familiarly like those employed when overhead wires were first installed, and which predicted tremendous loss of life to pedestrians who should happen to be in the way of falling wires. We make the following quotations:

> The undersigned begs to state that a careful inquiry made among the employees of the water board of Brooklyn brought to light the fact that they (the employees) were fully aware of the conditions as they existed and do exist at the present time, as they have been knocked down by the current while working upon water mains and, in some cases, severely injured, and in other cases badly burnt; and yet in this community such a state of affairs is permitted to exist, and, as far the records show, no effort has been made on the part of the insurance authorities to prevent it. And yet it could have been prevented, and if I may be permitted to say so, must be stopped now or the community at large will inevitably meet with nothing less than a conflagration when the conditions for such an event happen; and when they do happen the events will be coincident, and it may not only be a large loss of property by fire, but it may mean the loss of a great number of lives.
>
> Let us suppose, for instance, a case that can be readily imagined. What would have happened if a fire had occurred in Brooklyn among the frame buildings in the neighborhood of the break in the 4-ft. water main? This particular locality, as far as the buildings are concerned, would have been completely wiped out of existence, and lives would certainly have been lost in the general panic. This statement is not made by the undersigned for the purpose of appearing as an alarmist, but simply as an actual state of affairs as they exist to-day, only in far worse condition in other parts of Brooklyn.

The rest of the report is about on a par with the portion quoted. It is made up, as shown, for the most part of hearsay evidence as ridiculous as that contained in the paragraph given, together with opinions of the writer, based presumably upon this class of testimony. Nowhere in the report, so far as we can discover, has any attempt been made to determine the actual cause of the deterioration, or defect, in the pipe in question, the only point in which either the railway or the water company is really interested. If any injury had been done by the railway current, a thing which we very much doubt, what is wanted are *facts*, not opinions or hearsay, and such facts constitute the only evidence which merits consideration or would be admitted in a court of law.

There seems to be a lamentable effort on the part of interested persons to prejudice the position of the railway companies on this question in the minds of the public, and to create a feeling of anxiety by giving wide publicity to statements of this kind, without a word of comment. For instance, the report of Mr. Wilson, as published in the engineering paper already mentioned, has recently been widely circulated by some anonymous person or persons. On the back of the sheet containing the report is a scare photo-engraving of the break in Brooklyn. This throws no light on the *cause* of the disaster, but, coupled with the report, is undoubtedly intended to create popular distrust of the safety of the use of rails as return conductors, which is entirely unwarranted by the actual facts in the case.

Electrical World and Electrical Engineer

On and after March 11, "The Electrical World" and "The Electrical Engineer" will be merged together in a single publication under the name of the "Electrical World and Electrical Engineer." The "Electrical World" dates from 1874, and has just finished its first quarter century of life, during all of which time it has been owned and managed by W. J. Johnston. The "Electrical Engineer" dates from 1882, and was purchased from its former owners in 1890 by T. Commerford Martin and Joseph Wetzler, formerly editors of the "Electrical World." Mr. Johnston retires from the field of electrical journalism, and Mr. Wetzler will hereafter devote his energies to the building up of the Electrical Engineer Institute of Correspondence Instruction, organized a short time ago under the auspices of the "Electrical Engineer."

The editorial management of the "Electrical World and Electrical Engineer" will be in the hands of W. D. Weaver, until now editor of the "American Electrician," and T. Commerford Martin, editor of the "Electrical Engineer," both of long experience in electrical journalism, and with world-wide friendships and connections.

The business interests of the new paper will be in charge of J. M. Wakeman, long and favorably known in connection with the "American Machinist," while A. C. Shaw, until now business manager of the "Electrical Engineer," will be associated with Mr. Wakeman in the work of the paper in New England.

The "Electrical World and Electrical Engineer" will be built on broad lines and to high standards, and it is believed that it will easily take rank among the great technical and engineering periodicals of the world. The field of electrical engineering is constantly widening, and it is generally conceded that in the practical application of electrical science to utilitarian purposes America is in the lead among the nations of the world. It is intended that the best practice in all departments of electrical science shall be reflected in the columns of the new paper, and, with the concentration of editorial effort, until now divided between the two constituent periodicals, it is believed that the union of interests will be obviously advantageous to readers and advertisers.

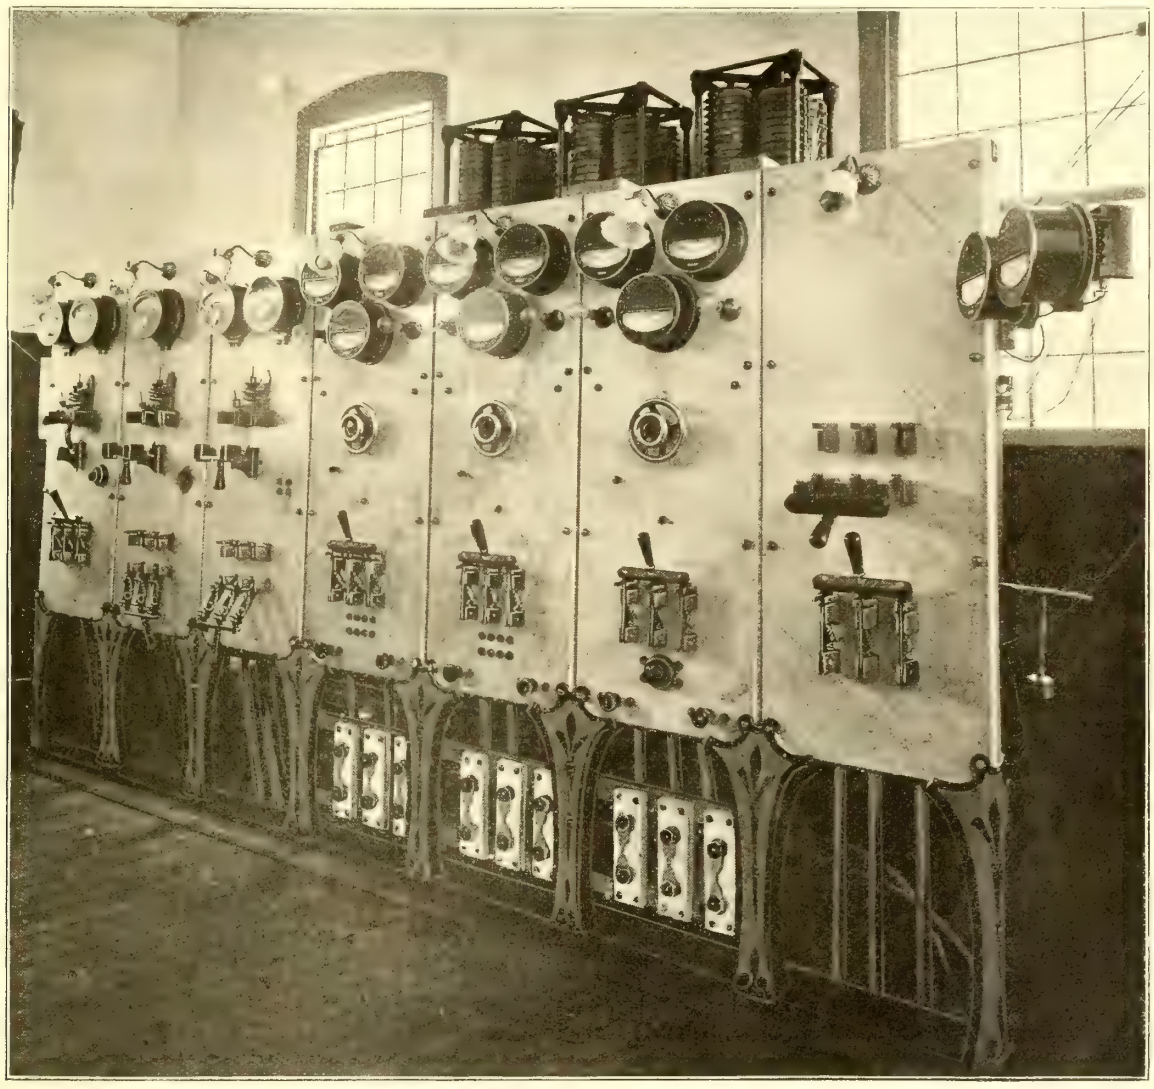
The purchase of these two properties and their consolidation has been brought about by James H. McGraw and his associates of the Street Railway Journal, and among others who will be largely interested in the "Electrical World and Electrical Engineer" will be Messrs. Wakeman, Martin and Weaver and Shaw.

Three-Phase Transmission for Electric Railway Work in Maine

The growing number of interurban electric railways in which the power for operating the cars has to be transmitted over considerable distances has made the subject of high potentials an extremely important one. While no road in this country has yet attempted the use of three-phase motors on its cars, the high economy of distributing power by the three-phase system has led to its careful investigation by a number of companies. Among these is the Lewiston, Brunswick & Bath Street Railway, which has recently put in operation a line 30 miles in length, from Lewiston to Bath, Maine, with urban branches at both ends, making a total of 60 miles of track. The entire system is supplied with power from one hydraulic power station in Brunswick, and contains a number of novel features, including the distribution in Brunswick from one type of generator only.

The Lewiston, Brunswick & Bath Street Railway Company was formed July 1, 1898, by the consolidation of the Lewiston & Auburn Horse Railway, the Bath Street Railway and the Brunswick Electric Railway companies, and is capitalized for $500,000. It has a bonded indebtedness of $1,000,000 in 5 per cent bonds, of which $300,000 are held in the treasury for future construction and purchases. Among the chief members of the syndicate which organized and built the road are I. C. Libby and A. F. Gerald, both of whom are prominent in electric railway interests in Maine. The power for operating the line is obtained from a fall in the Androscoggin River, owned by the Cabot Company, and largely used for industrial purposes. From this company the railroad leases 1000 h.p. at the rate of $10 per h.p. per annum.

The power station at Brunswick is a small brick building near the mills, and contains four Victor wheels, all mounted on the same shaft and operating under a 17-ft. head. These wheels are controlled by Lombard governors, and, by means of a rope drive, operate the main countershaft, to which the three main generators are belted. The generators, illustrated in Fig. 2, are double-current machines, designed to deliver from one winding both alternating and direct currents, being the first machines in the country to be used in this way. Each generator is of 250 kw. capacity, the whole of which may be delivered from the commutator at one end of the armature, from the collector rings at the other, or in any proportion through the two simultaneously. They were built by the Westinghouse Electric & Manufacturing Company, have twelve poles, and run at 1600 r.p.m., delivering alternating current therefore at sixty cycles per second. The direct current voltage is 500 to 550, and the alternating three-phase voltage runs from 300 to 330 volts, as it comes from exactly the same windings.



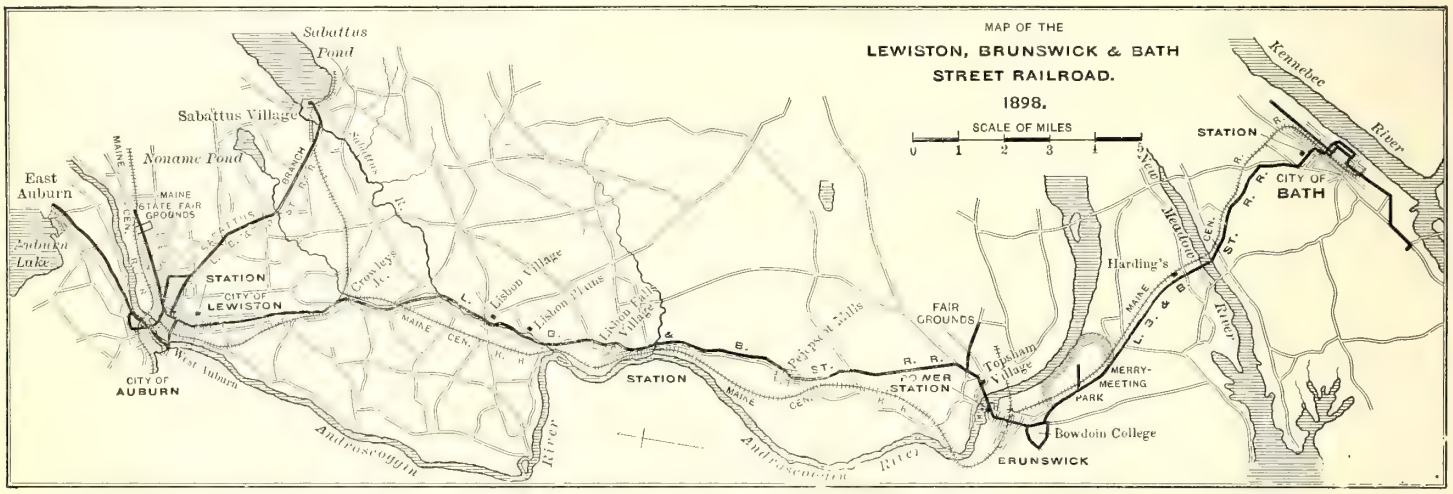


FIG. 1.—SWITCHBOARD AT MAIN GENERATING STATION

The switchboard, which is illustrated in Fig. 1, is made up of two types of panels, one closely resembling standard

railroad generator panels, and the other standard alternating panels. There are three of the former, located at the left end, as shown in the accompanying illustration, each equipped with circuit breaker, ammeter, pilot lamps, voltmeter receptacle and triple-pole, quick-break main switch, but with no field rheostats. Each of the alternating panels, of which there are three, carries three alternating ammeters, one for each phase; a triple-pole, single-throw main switch, for throwing the machine on to the one set of three-phase bus bars, the field plugs and field rheostat.

the latter of No. 1 wire as far as Lisbon Falls, where there is a rotary substation, and No. 3 copper wire for the balance of the distance. The wires are carried on porcelain insulators, mounted on the same poles which carry the brackets for supporting the trolley wires.

There are three substations, one at Lewiston, having two 200 kw. rotary converters, fed by three 150 kw. transformers; and one each at Lewiston and Lisbon Falls, each containing one 200 kw. rotary converter fed by three 75 kw. transformers. The latter are of the oil-insulated, self-

There are, of course, no ground detectors on these panels, as the winding is grounded through the direct current end.

The transformer house for the alternating current is located about 45 ft. from the station, on account of insurance requirements. It is a two-story brick building, about

cooling type, and, like the generators, are connecting in the star or Y grouping. The rotary converters are ten-pole machines, running at 720 r.p.m., and are similar in winding and details to the generators. Overhanging the bearing at one end of the shaft is a small three-phase induction motor for starting, and overhanging the bearing at the other end is a pulley by which the machine can be driven

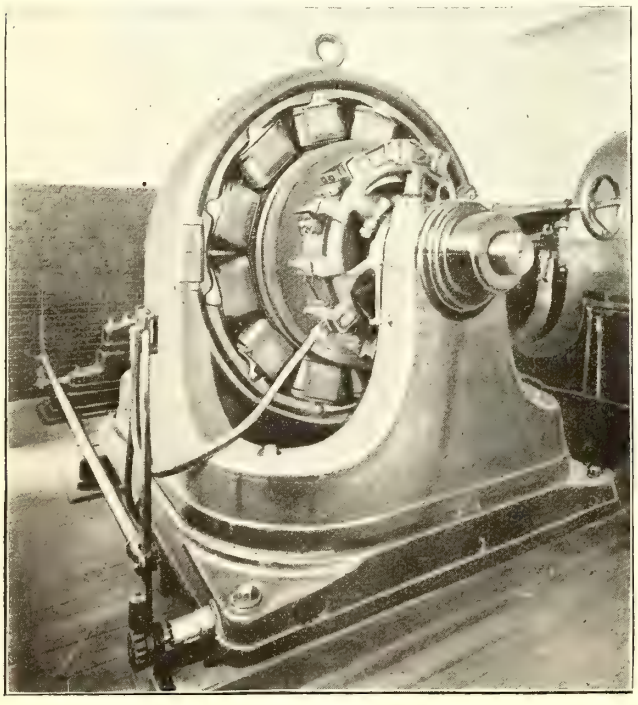

FIG. 2.—A. C. D. C. GENERATOR AT MAIN POWER HOUSE.

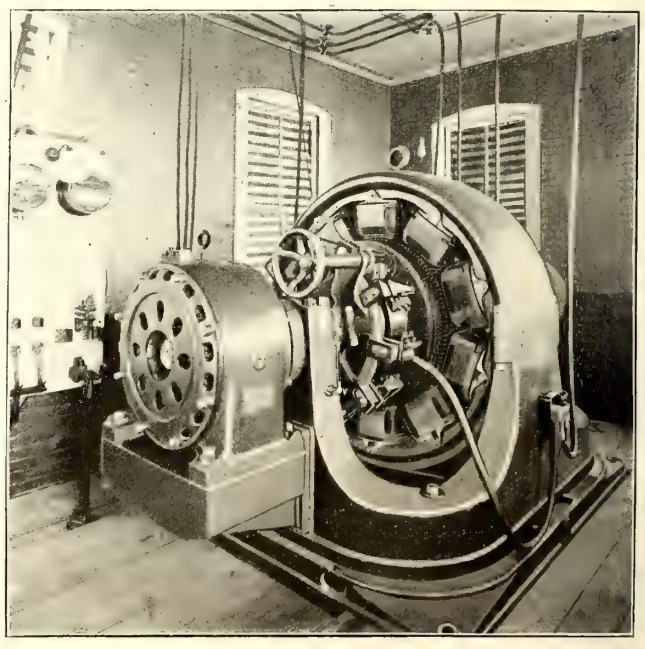

FIG. 3.—ROTARY CONVERTOR AT BATH

18 ft. x 24 ft., and the current is carried to it by lead-covered cables. The step-up transformers are six in number, of the Westinghouse oil-insulated, self-cooling type, of 125 kw. capacity each, and raise the current to a line pressure of about 10,000 volts. From this transformer house two high tension lines are run, one to the city of Bath, 10 miles distant, and the other 20 miles, to the city of Lewiston. The former consists of No. 6 wire, and

by steam engine, which will be installed later for emergency work.

The 30 miles of main line consists of a single track laid with 60-lb. T rails in 60-ft. lengths. About 7 miles is on private right of way 33 ft. in width, the balance following the side of the highway. The country is quite hilly, and the track follows the contour, its maximum grades being about 10 per cent. The cost of

the track, exclusive of right of way and inclusive of the overhead work, was about $10,000 per mile. The overhead line is thoroughly put up on 30-ft. poles with 7-in. tops, placed 115 ft. apart. At the top they carry four-pin cross arms supporting the high tension line, another similar line below carrying the 500-volt feeders, which are of bare copper wire, all copper in the system, including trolley, feeders and 10,000-volt lines, being uninsulated. The trolley wires are two in number, one for the up and the other for the down cars, of No. 0 copper, supported in special hangers consisting of one rigid piece, carrying the caps and cones for both trolley wires. One No. 0000 feeder is carried the whole length of the line, constituting a short distributing main or side feed. The section breaks are short-circuited through switches on the poles, thus tying all 500-volt copper together.

The main line traffic is carried by nine cars, giving a half-hour service, the run of 30 miles being scheduled at $2\frac{1}{4}$ hours. The cars are mounted on single trucks, with two Westinghouse No. 49 motors, and fitted with extra wide bodies and cross seats. Each car makes four round trips, aggregating 264 miles per day, with a change of crew each round trip. A dozen cars more run on the local lines in Lewiston and Bath. The through line has been running since the middle of August, and doing a very satisfactory winter business. For summer service it is equipped with ten fourteen-bench open cars, on Peckham double trucks, fitted with two Westinghouse 50-h.p. motors geared for medium speed. Ten more such cars will be added before the summer season begins. During the winter season these motors are used for snow plows, of which there is naturally considerable need in the wintry climate of the State of Maine. Besides six Taunton-nose plows, there are two Ruggles rotaries, each fitted with two 50 h.p. driving motors and one 50-h.p. motor to run the centrifugal fans. The latter are very powerful, fitted with cutting blades to draw in the snow and centrifugal paddles to throw it to one side, both being 88 ins. in diameter.

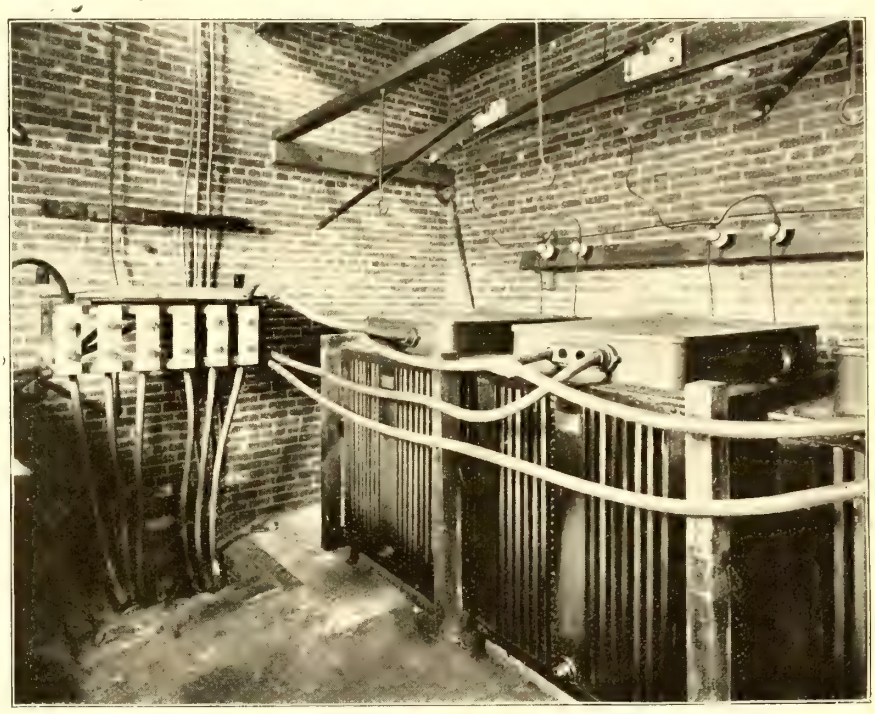

FIG. 4.—STEP UP TRANSFORMERS AT TRANSFORMER HOUSE

FIG. 5.—INTERIOR OF CONVERTOR STATION AT LISBON FALLS

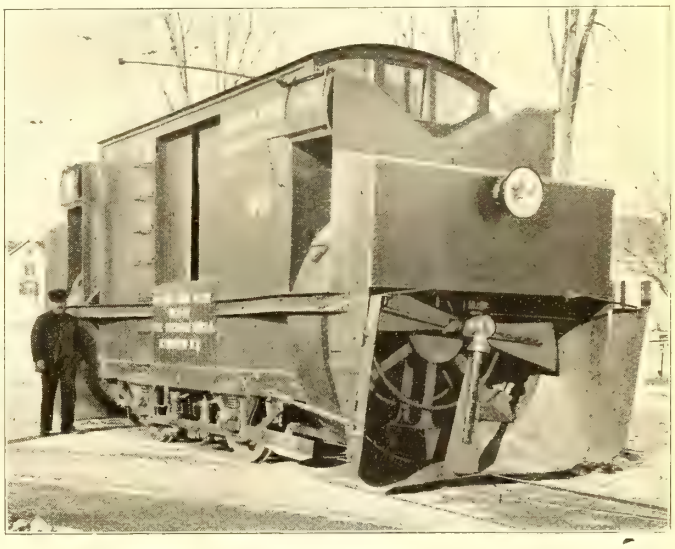

FIG. 6.—ROTARY SNOW PLOW

The through fare for the 30 miles is 35 cts., the route being divided into seven sections, with fare of 5 cts. per section. The road shows gross earnings during the winter months of from $350 to $700 per day, its cost of operation and interest on the bonds being $350 per day. It is expected that the daily earnings will run up to $5,000 per day in the summer months, when the pleasure travel is at its maximum. The company owns a large park on Merry-Meeting Bay, which will attract considerable travel. It has also entered into an agreement with the Kennebec Steamboat Line, running from Bath to Boston, to carry through passengers, freight and express matter,

and will put on special cars for the carriage of baggage and other inanimate traffic.

The officers connected with the line are: President, A. H. Shaw, treasurer, I. C. Libby; general manager, A. F. Gerald, and general superintendent, I. L. Meloon, to whom thanks are due for the information given above.

The electrical apparatus was installed under the general

direction of E. Chesrown, representing the Westinghouse Company, who lately left to take a position with the Snoqualmie Transmission plant in the State of Washington. His successor is W. G. McConnan.

New York City Quarterly Reports

The trend of traffic in New York City is indicated by the following reports of the Metropolitan (surface) and Manhattan (elevated) companies for the quarters ending Dec. 31, 1897-8:

METROPOLITAN STREET RAILWAY COMPANY

Quarter ending Dec. 31,	1897.	1898.
Receipts from passengers	$2,383,458	$3,092,756
Receipts from other sources	150,919	175,190
Receipts, total,	2,534,377	3,267,946
Operating expenses	1,208,770	1,467,580
Earnings from operation	1,325,607	1,800,366
Deduction from earnings—		
Interest on bonds	107,500	263,750
Taxes	130,431	159,617
Rentals	551,075	649,690
Net income	536,601	727,310

MANHATTAN RAILWAY COMPANY

Quarter ending Dec. 31,	1897.	1898.
Receipts from passengers	$2,597,186	$2,356,896
Receipts from other sources	45,625	47,500
Receipts, total,	2,642,811	2,404,396
Operating expenses	1,358,085	1,341,090
Earnings from operation	1,284,726	1,063,306
Fixed charges	774,855	731,784
Net Income	509,871	331,522

The New South Terminal Station in Boston and its Effect on Traffic Conditions in Eastern Massachusetts

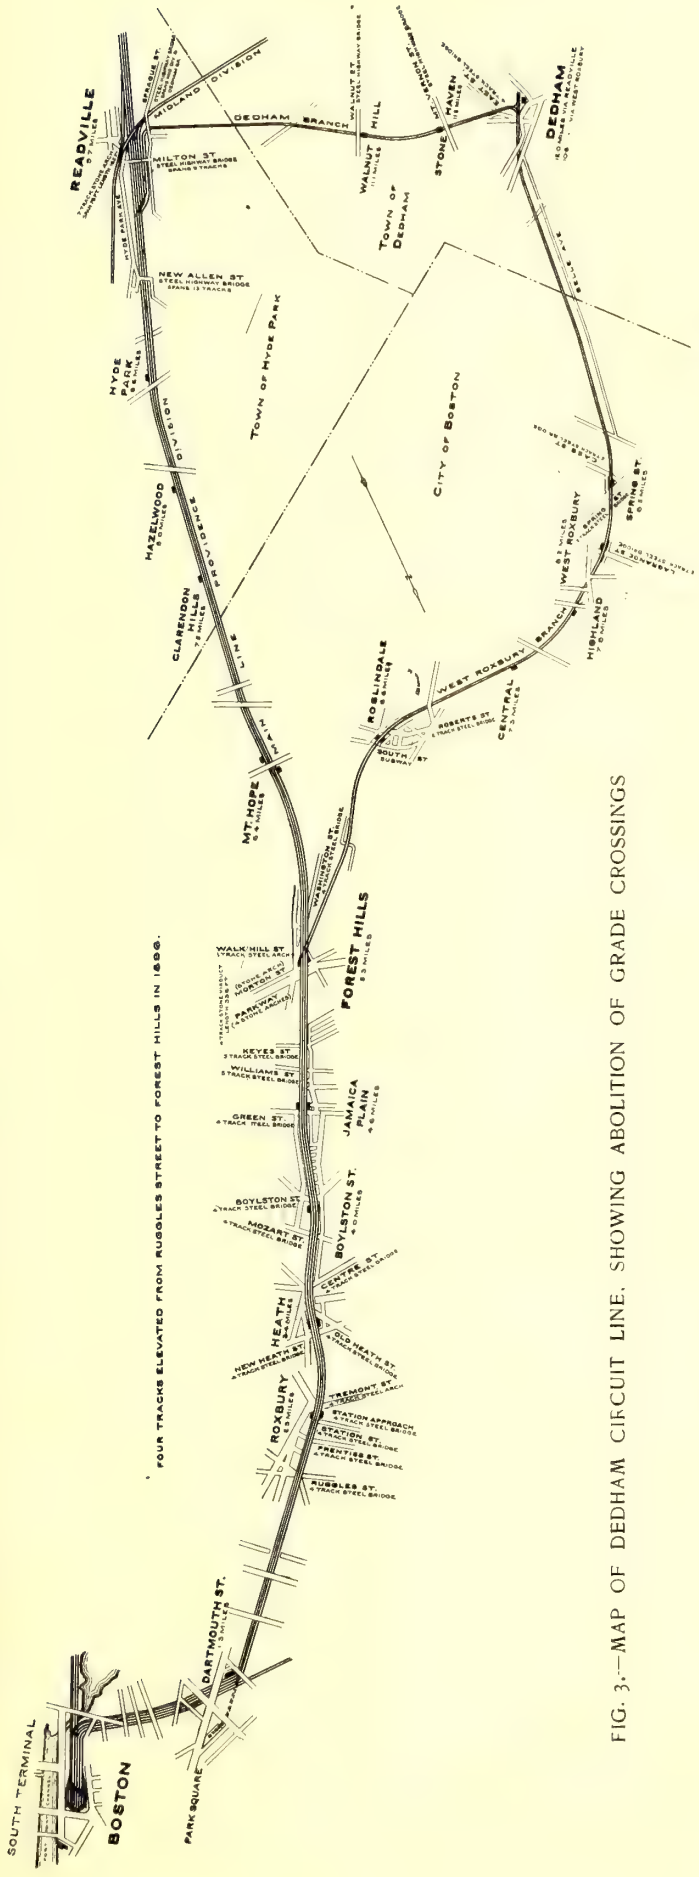
It appears that the New York, New Haven & Hartford and the Boston & Albany Railroads are determined to regain the rich suburban traffic in and out of Boston, which they have been steadily losing to the electric street railways of Eastern Massachusetts during the past few years, and that they mean to fight the enemy with its own weapons, so far as may be possible. No other interpretation can be put upon the building, at great expense, of the new Southern Terminal Station in Boston, at a point more convenient of access to the heart of the business section for the large majority of the users of the railroad systems than are the present stations; upon the elimination of grade crossings in the suburban district, and an increased number of suburban stations; and upon certain peculiar features found in the plan of the new South Terminal Station in Boston, by which its train-handling capacity is enormously increased. Literally, as well as figuratively, one may look below the surface of things at the new terminal and find food for reflection and for predictions as to the future. A brief description of this new station, with its peculiarities, and a discussion of its certain influence on the transportation conditions of Eastern Massachusetts will reveal some things of the greatest interest and importance to railroad and street railway managers and engineers, and to the general public.

A few years ago there were four railroads serving Southeastern and Western Massachusetts, entering Boston from the southern side. These railroads were the Boston & Albany, the New York & New England, the Boston & Provi-

FIG. 2.—MAP OF BUSINESS SECTION OF BOSTON, SHOWING NEW SOUTH TERMINAL AND ITS APPROACHES

------ Abandoned lines

dence, and the Old Colony. Now, the three latter have been purchased and practically consolidated with the New York, New Haven & Hartford Railroad, which has three stations—the Providence Station, located at Park Square; the Old Colony Station, on Kneeland Street, and the New England Station, at the foot of Summer Street. The Boston & Albany Station was also on Kneeland Street, near the Old Colony Station. The locations of these stations are shown in Fig. 2. The lines of the Old Colony, Providence and New England Railroads parallel each other to a certain extent in Southeastern Massachusetts, the Old Col-



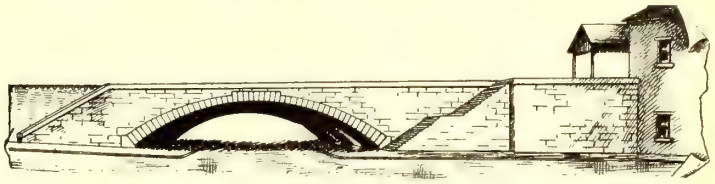


FIG. 3.—MAP OF DEDHAM CIRCUIT LINE, SHOWING ABOLITION OF GRADE CROSSINGS

ony, however, serving many portions not reached by the other two.

These four stations are all to be given up, and a new terminal station, constructed on the site of the former New England terminus, with additions, will replace them. The station is now completed, and the Old Colony and New England trains are using it, the Albany and Providence trains still running into their old stations. The new station location and the changes in the lines leading there-

ARCH CROSSING AT HYDE PARK AVENUE, DEDHAM CIRCUIT

to are noted in Fig. 2. The new station is nearer the financial, business and shopping districts of the city than the old stations, and it will be within quicker reach of the Northern Union Station and the northern ferry lines. When the new elevated structure is built, and with additional surface railway accommodations, the terminal facilities as a whole, including the new and large outlying station at Dartmouth Street, will inevitably be far more convenient to the mass of suburban residents doing business in Boston proper than are the present stations.

The map, Fig. 1, shows the network of railroad lines in Eastern Massachusetts which will use this new station, and gives an indication of the number of people resident in the district within 50 miles of Boston. The world is too apt to consider Boston as a fourth or fifth rate city, forgetting that in addition to the half million people contained within the city limits proper there are from sixty to seventy cities and towns in the immediate neighborhood which swell the population of the metropolitan district to about 1,250,000, while there are nearly 2,500,000 people within a 50-mile radius of the Statehouse. It will easily be seen from this map how intimate is the relationship between the railroads and the townships of Eastern Massachusetts, scarcely one of these towns being without good railroad connection to Boston. It must be equally evident that if the railroads adopt what may be called modern methods in the conduct of their suburban business they will be dangerous competitors indeed to the street railway companies. These modern methods include cars or trains run at regular and frequent intervals throughout the day, so that a would-be passenger may always know, without looking at a time-table, when an inbound or an outbound train is due; higher average speeds than are possible with present steam locomotive service; the doing away with the smoke, cinder, gas and noise nuisances incident to steam railroad operation; the cultivation of pleasure travel; a reduction of fares, made possible by greatly increased business; and uniformity of fares with zone limits, so far as this desirable feature can be introduced.

In other words, modern methods mean primarily electricity as a motive power, and electricity is surely going to be the motive power of the suburban railroad system of Eastern Massachusetts. The physical conditions are all favorable, especially since the passage of the grade-crossing bill in Massachusetts, under which the State, the different cities affected, and the railroads are joining hands for the abolition of the grade crossing evil. The increasing competition of the electric street railway lines compels it, and the railroad companies have realized the situation and taken steps accordingly, as will presently be seen.

Glancing again at the map, Fig. 1, it will be seen that

there are numerous loop lines already established in this suburban area, adapted to a service of the kind just spoken of. Loop lines are a decided advantage in that trains can be kept constantly in motion, without delays and lost time for switching and other purposes, and a regular short interval schedule can easily be kept up. The line which will probably be the first around Boston to be equipped by electricity is that known as the Dedham circuit, one branch of which is made up of the four-track main line of the Providence division, New York, New Haven & Hartford Railroad, between the new Southern Terminal Station in Boston, and Readville, while the loop leaves the main line at Forest Hills and passes through a succession of pleasant residential settlements to Dedham, joining the main line again at Readville. A plan of this line is given in Fig. 3, from which it will be seen that grade crossings have been entirely eliminated from it, and it is now "cleared for action," as it were, ready for electric traction. On this Dedham Circuit line trains run, at present, at hourly intervals, though with greater frequency during the rush hours. Under the new conditions it is quite probable, though no decision has yet been made, that a regular train service at ten or fifteen minute intervals will be kept up throughout the day, using single cars or two-car trains only during the lighter hours, while three, four, or five car trains may be run at other hours, according to the demands of traffic. Another line on which a service of this general character can be put, to the advantage of the steam railroad companies and the people, would be the Newton Circuit line of the Boston & Albany Railroad, which passes through the richest suburban territory in the vicinity of Boston. Several other loop lines could be made along the South Shore, and the Nantasket Beach electric line, if extended to Boston, would, it is hardly necessary to say, be highly popular, and probably far more profitable than is the present mixed steam and electric service.

All these plans for reorganizing suburban transportation methods necessarily involve terminal facilities far greater than can be ordinarily obtained by a stub-track system, where switching of locomotives and delays of one kind and another are inevitable. As a consequence, the new South Terminal in Boston has adopted a plan unique in the annals of steam railroading. It is planned that all suburban trains shall eventually enter the terminal and pass down depressed tracks into a subway loop, where, at properly located platforms of large area and length, they will discharge and receive loads, and will thence pass up out of the subway on inclined tracks to the surface again, on their return journey. By this simple plan the total train capacity of the South Terminal Station is increased from some 750 trains per day, which is all that the twenty-eight stub-tracks entering the terminal could handle with safety, to over 2000 trains a day—a station capacity larger by far than that of any railway terminus in the world.

A plan of the Southern Terminal is seen in Fig. 4, and a section in Fig. 6. From these the location of the loop can be readily understood, and it will be seen also from the curvature of the outer loop (262-ft. radius) that it is only in a station of such enormous size that a scheme of this kind is feasible. The platform capacity of the two-track loop in the subway is sixty cars, each 40 ft. in length, a capacity greater than will probably be called for for some years to come; and the inner loop will be used only if the traffic should eventually exceed the capacity of the outer. Passengers will enter the main station and pass down stairways to the loading platform, which is that between the two tracks, and which will accommodate 25,000 people at a time. Here will be gates and penstocks, from which the trains for given lines will depart, and these penstocks can be filled before the arrival of the train. The unload-

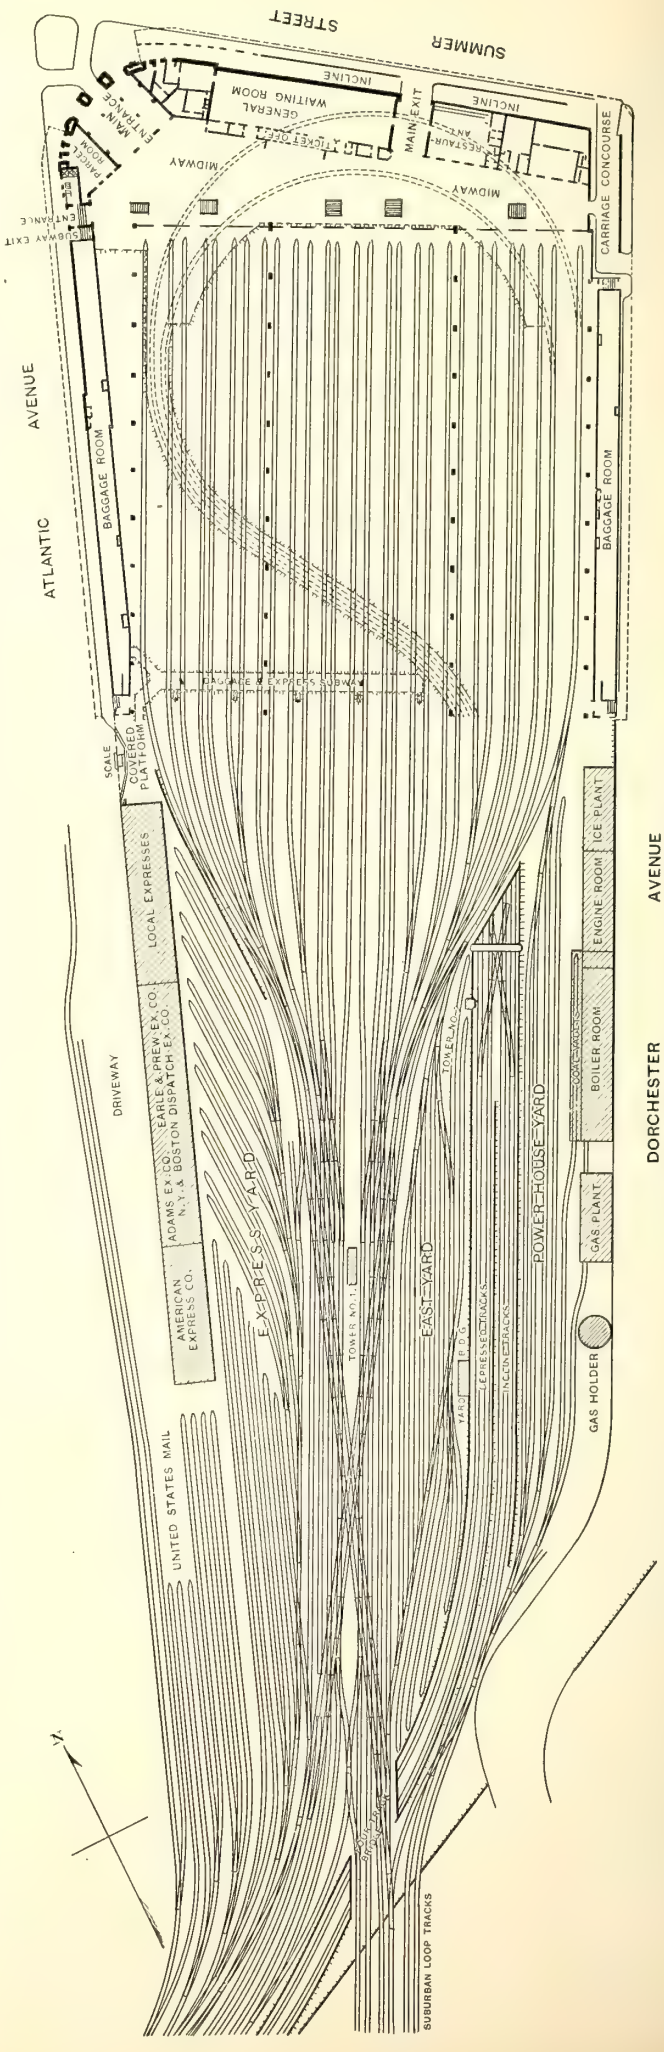

FIG. 4.—TRACK AND STATION PLAN OF THE NEW SOUTH TERMINAL, BOSTON

ing platforms will be on the outside of the loop, and from it passengers will find an exit directly to the street, with little obstruction to the outward flow. When the inner track of the loop is used it will, of course, be necessary to make the innermost platform an unloading one also, and from it passengers will have to find an exit to the midway above, or over stairways and bridges to the outer unloading platform. This plan is, of course, less desirable than the first, but is a necessity of the situation. The inter-

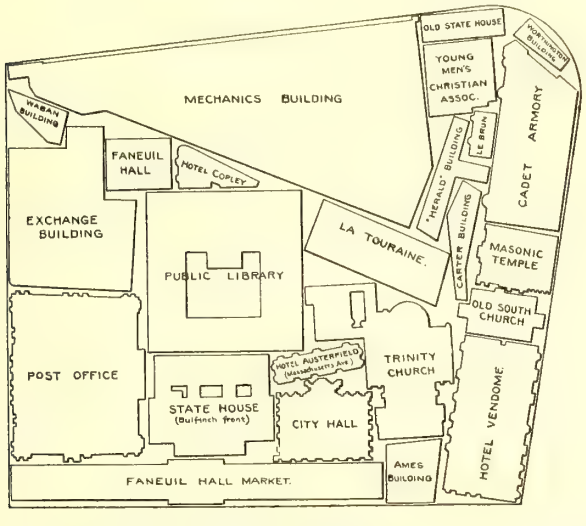

FIG 5.—DIAGRAM SHOWING SIZE OF HEAD HOUSE, NEW SOUTH TERMINAL

locking switching arrangements in the yard above are such that a train can be passed out of the subway every sixty seconds, and as there is platform space for four trains on each track, there is thus provided ample time for loading and unloading.

The terminal building itself is a magnificent and imposing structure, particularly when seen from above in a "bird's-eye view." It is difficult to form a conception of the immense area covered by the building itself unless in some such way as that shown in Fig. 5, where it is seen that no less than twenty-four large Boston buildings could be contained within the limits of this single one. The building alone, exclusive of the yards, extends south along Atlantic Avenue 792 ft., and east on Sumner Street 672 ft., while the frontage on Dorchester Avenue is 725 ft. The train shed is 602 ft. long x 570 ft. wide, and contains twenty-eight tracks having an aggregate length under roof of 4 miles. These tracks are arranged in pairs, with a passenger platform between each pair, and between the pairs are seven platforms devoted exclusively to the trucking of baggage and express matter. The baggage is handled by elevators, which pass up and down from the baggage platforms to a subway below, whence they are trucked to and from the baggage rooms.

The midway at the end of the train shed is a magnificent stretch of platform space, containing 60,000 sq. ft., extending the entire Summer Street length of the building and reached from the street by broad inclined walks, and from the waiting rooms through many doors. Eleven windows of the central ticket office open toward the midway, and sixteen windows open into the waiting room. The station accessories in the matter of waiting rooms, lavatories, restaurant, barber shops, telegraph and telephone offices, electric elevators, etc., are well planned for the comfort and convenience of passengers, and little is left to be asked for by the traveling public. The inward baggage rooms are on the east side, and the outward on the west side.

Never before has a great railroad station been provided with such extensive and elaborate equipment requiring the use of power, and as a consequence never before has a station power plant been so interesting. Much time has been spent in the study of other terminal stations at home and abroad for the purpose of introducing the best features found therein, but in addition to these, others entirely unique are met with here for the first time. There is an elaborate system of interlocking switching and signaling apparatus for the yards and train shed, all worked by compressed air, and requiring, therefore, a suitable compressed air plant; steam for heating and for various other purposes; electricity for elevators, the ventilating system, fans, and a half-hundred other purposes; an ice plant for the manufacture of ice used in the cars, restaurants, etc.; a refrigerating plant for cooling the provision boxes and storage rooms in the headhouse; a plant for filtering and cooling drinking water for the public and for use in the offices; mains for heating cars when standing in the train shed and yards when locomotives are detached; charging apparatus for air-brake appliances; a fire protection service for the terminal buildings; a pumping plant for disposing of water which may find its way into the portions of the terminal situated below tide water;—all these depend upon the general power plant, which is located on the Dorchester Avenue side of the building. The building devoted to this purpose is 460 ft. long and 40 ft. wide.

A general contract for practically the entire engineering and power equipment of the terminal was placed by the Terminal Company with Westinghouse, Church, Kerr & Co., who have in turn sublet contracts for all the detail appliances not manufactured by themselves. The entire equipment is as follows:

There are ten horizontal tubular boilers, built by Edw. Kendall & Sons, of Cambridgeport, Mass., each 72 ins. in diameter x 18 ft. long, with 130 3-in. tubes. Each boiler is equipped with Roney mechanical stokers operated by two standard Westinghouse engines.

There are two economizers of the Westinghouse steam

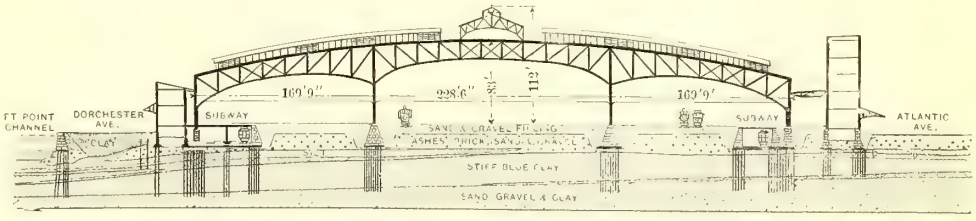

FIG. 6.—TRANVERSE SECTION, NEW SOUTH TERMINAL

circulating pattern, manufactured by the Fuel Economizer Company, of Matteawan, N. Y.

There is no chimney to the plant, but forced draft is used and is supplied by two blast wheels 14 ft. in diameter x 7 ins. wide, designed by Westinghouse, Church, Kerr & Co.

In the engine room are four 375-h.p. Westinghouse automatic compound condensing engines, each direct connected to a Westinghouse 8-pole, 220-volt direct current dynamo of a peculiar type, each dynamo being capable of generating a 220-volt current for power purposes and a 110-volt current for arc and incandescent lighting, both currents being deliverable in any desired proportion from the same machine.

The heating of cars waiting in the train shed in cold weather when the locomotive is detached is provided for by a complete system of steam mains leading to the ends

of the stub tracks, steam at boiler pressure being passed through a reducing valve which supplies the mains with steam at 70 lbs. pressure.

A thirteen-panel switchboard is another feature of the power plant.

The air compressors were made by the Ingersoll-Sergeant Drill Company, and have 12-in. steam and 10-in. air cylinders with 24-in. stroke. A constant pressure of 100 lbs. is kept in the pneumatic signaling apparatus and interlocking system.

A positive hot-water circulating system is used for heating the station.

The ice and refrigerating plant was designed by Westinghouse, Church, Kerr & Co., and is especially complete and interesting.

The Sprague Electric Company has furnished four electric passenger elevators of its Z type, two freight elevators of the Q type, and twelve baggage lifts of type P, the last named operating between platforms in the train shed and the baggage subway below.

The electric pneumatic interlocking system was furnished by the Union Switch & Crossing Company, a Westinghouse corporation.

A complete gas plant for supplying compressed illuminating gas on the "Pintsch" system has been installed in a separate brick building at the south end of the power house. Its capacity is 120,000 cu. ft. per day.

The exceptional completeness of the equipment of the South Terminal Station and the perfection of the plans in every detail is due, of course, to the combined intelligent effort of many men on the magnificent staffs of the Boston & Albany and New Haven Companies, but among those especially to be mentioned as bearing the final responsibilities are President Charles P. Clark, of the New Haven system and the Boston Terminal Company; General Manager John C. Sanborn and Resident Engineer George B. Francis, of the Terminal Company, and Chief Engineer Curtis, of the New Haven Company. The advantages of making a bulk contract for the entire engineering equipment have been well exemplified in the care and celerity with which the work has been carried out by Westinghouse, Church, Kerr & Co.

LOADING PLATFORM ON LOOP IN SUBWAY

Consolidation in Buffalo

On Feb. 27 it was announced that all the electric railways in Buffalo and vicinity had been purchased by a syndicate, and would be consolidated into one company having a capital stock of $25,000,000. The roads purchased are the Buffalo Railway Company, the Buffalo Traction Company, the Buffalo & Niagara Falls Electric Railway Company, the Buffalo & Lockport Electric Railway Company, the Buffalo, Bellevue & Lancaster Railway Company and the Niagara Falls Park & River Railway Company, of Niagara Falls, Ont. In addition to the purchase of the electric railways the syndicate gains control of two bridges crossing the Niagara River below the falls, one of them being the upper steel arch bridge, and the other the new suspension bridge now being erected over the river at Lewiston.

SOUTH TERMINAL STATION, BOSTON

A verdict for $400 has been given to a gentleman in Brooklyn, N. Y., who was ejected from a car by a conductor. The gentleman received a transfer from one line to another, but as the cars of the second line were crowded he decided to wait until he could secure a seat. A car containing empty seats did not pass for half an hour, and when the gentleman presented the transfer on this car it was refused on the ground that the time limit had expired. He was ejected from the car, and brought suit, with the above result.

A decision has been handed down by the full bench of the Massachusetts Supreme Court in the suit against the Warren, Brookfield & Spencer Street Railway Company, holding that a landowner cannot recover damages for injuries caused by the construction of an electric railway in front of it. The court holds that the law granting damages is not applicable to street railway companies, but only to companies organized for the production of electricity for power or lighting.

The Brooklyn (N. Y.) Rapid Transit Company reports passenger earnings for February, 1899, as $370,544.

Park Amusements

BY HENRY PINCUS

The entire success or failure of a park is almost entirely dependent upon the proper selection of attractions, and yet many park owners look upon this as a mere secondary consideration. I have known large corporations to invest many thousands of dollars in park property, and, after months of preparation for a season's business, never give their amusements a thought or consult an amusement manager until the last moment, and oftentimes not at all. In their opinion, the amusement manager does not count for much—he is only a "showman"—and what are his suggestions and advice worth, compared with those of the engineer, architect, landscape gardener, and such persons?

Why is an amusement manager so necessary, particularly at the start? What does he know about the details of laying out a park? These are the questions I propose to answer.

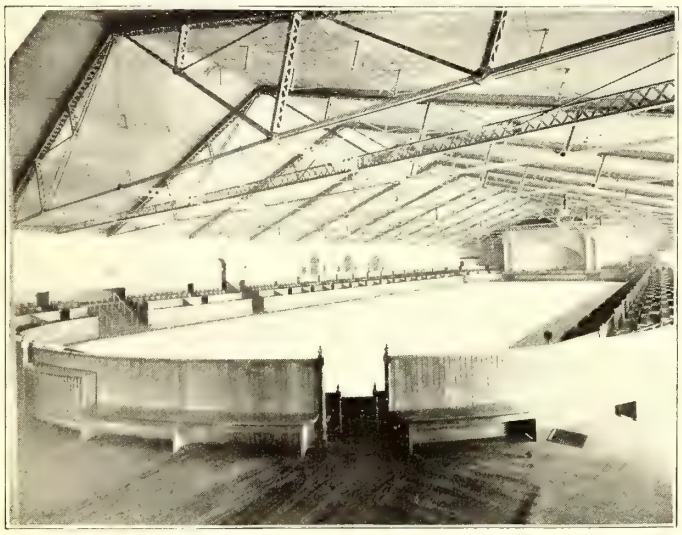
A man who understands the business of park amusements should have a general knowledge of the entire subject. By this I mean that he should see at a glance where to locate this or that attraction with a view to getting the best results, make it easy for the people to see and hear, and, at the same time, make it easy for them to spend their money. This is a science, and an expert amusement manager knows all the tricks that go to accomplish this end. The park is designed for amusement and should be built upon amusement principles, and the larger and more pretentious the park, the greater the need of an experienced man. Why? Because in all enterprises, everything revolves around one pivotal point, that for which it was organized. For instance, who would think of exploiting a mining scheme without a mining expert? Just imagine a large department store without a competent buyer for the various departments. All the magnificent buildings, handsome decorations and perfect surroundings would amount to very little, if the right kind of goods were not there. So it is with amusement parks—beautiful grounds, fine structures, and unlimited capital to operate them, do not make successes—the "attraction" is the thing, that magnetic "something" which you must depend upon to draw the people.

Strange as it may seem, the park proposition differs from almost every other form of amusement enterprise. Let me explain. In a theater, for instance, the entire audience are really all in and seated when the performance begins. Their admission fee, which is all the revenue the owner expects to get from them, has been paid. It is now the desire of the proprietor to entertain the patrons to the best of his ability for the entire evening and give them the worth of their money. If the attraction is strong enough to draw the people, it certainly must be interesting enough to hold their attention for the entire length of performance. This is what is wanted. It is not so with parks, however. In out-door amusements, the successful manager must keep his patrons "on the go" all the time. The entertainment must be of such a character as to be sufficiently strong to draw the people, and, at the same time, to keep them entertained *at intervals only*. Why? Because they must be kept moving. The "show" is only the "bait" to catch the crowd, it is the expensive end from which the owner receives no revenue, or very little.

What are the profitable sources of income? The merry-go-round, the toboggan, the thousand and one catch-penny amusements; they are the money earners. The candy, ice cream and soda water stands and such must get their share also. They are scattered all over the grounds. What chance have they to do business if the people are all seated in the amusement pavilion and kept there for the entire evening? Yet there they will stay, afraid to leave their seats for fear of losing them. That is the objection in parks to comic operas, plays and similar attractions—they hold the attention of the audience from beginning to the end. In other words, it is a "story" which they are interested in hearing all through.

The park owner will naturally ask then, "What on earth should I give them?" That depends entirely upon the originality of the manager, style of place he is managing and class of people he is catering to. To illustrate, in a general way, if you have a large place, where crowds are to be amused, and, at the same time, separated from their money, I would suggest the following: In the pavilion put a first-class band of music (I mean one of reputation with drawing power) with occasional solos and novelties interspersed. In another part of the grounds, say some fireworks—elsewhere, maybe, a balloon ascension (illuminated) or other sensational act. This will keep the crowd moving and, at the same time, enable the park owner to catch the nimble nickel. Take, for instance, Washington Park on the Delaware, that I have been managing for several seasons; a matter of the greatest concern was how to entertain the crowds, and, at the same time, get their money. It is hard to do both. For instance, our park covers many acres of ground—we have two carousels, two toboggan slides, a shoot the chutes, Ferris wheel, maze, electrical building, refreshment stands and many other sources of profitable income. Now, to get the people distributed among these points, while the non-profitabe counter attractions are so great with only a few hours to get their money, is a problem. In the evening, it is after 8 o'clock before the people can get to Washington Park from their homes and suppers, and by 11 o'clock they commence to go home. This makes the time very limited. We have two bands, electric fountain, fireworks, etc., all of which are free. After considerable experimenting, we settled on the following method:

At 8 o'clock the big band commenced their concert, which lasted until 8:40 (introducing special features). At 8:50 sharp (ten minutes later to give the people time to get there) commenced the electric fountain display, with its wealth of spectacular effects, living pictures and dances, in the midst of the falling waters. At the conclusion of this entertainment was a display of fireworks. This entire exhibition was all over at 9:20, just one half hour. One hour's show crowded into half that time and why? To keep the people from going home, as 9:20 was comparatively early, while at 10 o'clock they would make a rush for the cars or boats. Immediately at the finish of the fireworks display, the big band in the pavilion would strike up some lively march to attract the attention of those who had been watching the fireworks; this would have the effect of moving the crowd in that direction. Then there would be another concert with some novelty introduced, and the other band would play in the lower pavilion, which, together with the many other attractions distributed all over the park, would keep up the excitement until the end of the evening.



I have tried operas, concerts, vaudeville, big spectacles and water shows, as well as balloon ascensions, by day and night, in fact, almost every kind of attraction, all with the same result; *give it to them at intervals*. It is better to give operettas or selections from operas, with concert selections between, than one continuous show.

Remember I am speaking only of large parks covering great area. If you have a small park with nothing but a stage with seats in front of it, as the *only* attraction, as many of the small trolley parks do, then it is a very different proposition. In such cases a vaudeville, operatic or any other continuous evening's entertainment is just what is wanted.

Transformation of a Street Railway Repair Shop into a Skating Rink

As mentioned elsewhere the Consolidated Traction Company of Pittsburgh, has recently built extensive new repair shops, and this has allowed the company to remodel its former shops and to lease them as an ice skating rink. The building, which is of brick, has a ground dimension of 400 x 136 ft., and the ice surface utilized for skating aggregates 26,000 sq. ft. The skating floor is oval in shape, and is provided on three sides with rows of opera chairs and boxes. One end is fitted up with a stage or a band stand, and at the entrance or front end there are a large soda fountain, cloak rooms, parlors and smoking roms, as well as check rooms for skates.

The building is brilliantly lighted with arc and incandescent lamps, the latter being installed in great numbers along the steel arches which support the roof, there being

TRANSFORMED CAR HOUSE

but a single span. There are also artistic designs in incandescent lamps, and all the auxiliary equipments usually found in a rink of this character. The power for operating the ammonia compressors is derived from two 200 h.p. motors, which are converted generators, formerly employed in one of the power stations. These each drive a 150 h.p. compressor by means of individual rope belts. There is the usual tank and cooling apparatus through which the brine circulates, and the steam pump by which the brine is pumped through the tubes in the floor of the rink. The brine is returned through two large pipes located in the basement under the rows of seats on each side of the building. A portion of the basement is also occupied by one of the 248-cell storage battery stations of the chloride accumulator type, which are employed as auxiliary to the main power station. This battery is connected with the lighting circuit of the rink, so that the lamps burn very uniformly indeed. The switchboard for controlling the lights and power is also in the basement, the whole equipment being very liberally designed.

Every employee of a street railway should be considered as an agent with possibilities of harm to his employer. It is not enough that he be intelligent, sober and industrious. He should be of good judgment and sound thinking; and neither communistic, socialistic or anarchistic in his views; not discontented and at cross-purposes with the whole social order, but of cheerful disposition and content to make the best of life as he finds it.—From a paper read at the St. Louis Convention, 1896.

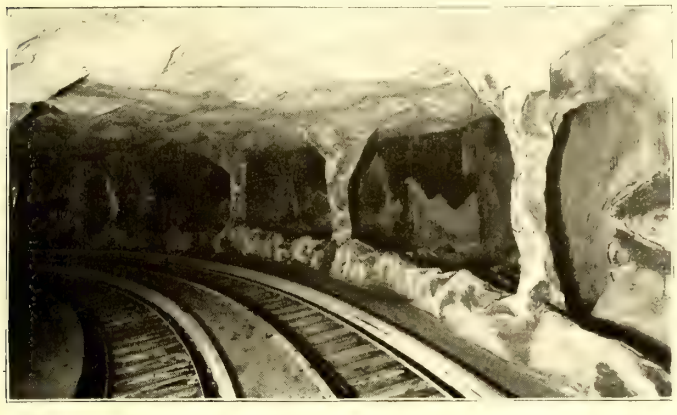
Woodside Park, Philadelphia

The Fairmount Park Transportation Company owns one of the most elaborate pleasure resorts to be found in this country. This is located a short distance from Fairmount Park in the city of Philadelphia, and nearly a half-million dollars have been judiciously expended in making it one of the most charming spots that can be imagined. The natural beauties of the place have been carefully pre-

SCENIC RAILWAY AT WOODSIDE PARK

served, and have been enhanced by artificial means wherever possible. The place is known as Woodside Park.

Among the many attractions are a Dentzel merry-go-round, a revolving tower, a large casino, from whose balconies magnificent views of Fairmount Park and the city can be secured, a well-managed theater, scenic railway, owned and operated by the L. A. Thompson Scenic Railway Company of New York, etc. These are only made adjuncts, however, to the natural beauties of the place, which consist of attractive woodland and groves, a very beautiful lake, numerous walks and drives, etc. Thousands of seats and tables have been scattered through the woods for the use of picnic parties, and these are always well patronized on pleasant days.



The scenic railway was the first attraction to be installed at this place, and was, in fact, nearly completed before any

LOOP BUILDING FOR RAILWAY

other improvements in the neighborhood had been undertaken. The railway is supplied with a power plant, which can be either steam or electric motor. The structure is built on the four-track plan, with loops at each end. The length of the structure is about 800 ft., 24 ft. wide, except at the loops, which are 62 ft. to 70 ft. across at the widest points. Each car travels four times the length of the structure, making a ride of about 3500 ft. Sidewalls are built along the structure the entire length of the track, making derailment impossible. The force used for the

greater length of the line is gravity. There is also a cable section centrally located in the structural roadway, where short sections of ¾-in. steel rope are driven up the main elevations by the application of steam or electric power. These running sections of cable pick up the cars while in motion by the use of an automatic grip attached to the bottom of the truck of the car, and the cars are carried up and over the elevations without the slightest jar or jerk, and automatically released at the top, so that the motion

GROTTO IN SCENIC RAILWAY

of the car is not checked. Here gravitation and momentum alternately supply the necessary force that propels the car over the roadway to the next cable section. At one terminal of the railway is a large pavilion, and at the other a circular building, through which the cars pass. Here,

GROTTO IN SCENIC RAILWAY

by means of painted canvas, etc., a number of very beautiful scenic effects are secured. These vary in character, from representations of distant views of mountains, hills and water effects to tunnels, from the roofs and walls of which depend imitations of coral, stalactites and grotesque formations of various kinds. The sensation, while passing through these tunnels and bits of scenery in the rapidly-moving cars, is novel and pleasing.

L. A. Thompson, the inventor of the attraction, was one of the first to study the question of developing the possibilities of gravity railways, and he has devoted fifteen years of his life to the problem. The company of which he is the head now operates over $200,000 worth of scenic railway plants in the United States, and is constantly increasing this amount. It is also receiving numerous inquiries from foreign countries, and has just sent two shiploads of material for scenic railways, one to Europe and one to South America. The company is now negotiating for a new site at Coney Island, where it expects to build the largest and finest gravity railway ever erected.

Electricity on the Manhattan Elevated Railway

George J. Gould, president of the Manhattan Elevated Railway Company, of New York, has issued to the stockholders of the company a circular, of which the following is an abstract:

"Pursuant to the request of the board of directors of the Manhattan Railway Company, I have been conducting during the past year a most exhaustive investigation relative to a change of motive power on the railways of this company.

"These investigations have embraced the generation, distribution and use of electric power on both elevated and surface railways by every important plant in this country, particularly those in New York, Brooklyn and Chicago. They represent, therefore, the combined experience of the largest producers and consumers of electricity in the world. The most conservative estimates made by experts show a saving of 2½ cents per car-mile on the entire car-mileage of the elevated roads. As we are now running over 40,000,000 car-miles annually, the saving in operating expenses alone will be over $1,000,000 a year, which, with other economies possible, is sufficient to pay 5 per cent on the $18,000,000 capital which it is proposed to put into the elevated roads, and 1 per cent additional on the present capital.

"This result will be effected merely by the decrease in expenses of operation, even if the effect of the change of motive power and other improvements connected therewith should not add one additional passenger to the present traffic. An equally strong reason, in my judgment, for the change of motive power is afforded by the increase in traffic, which will result as a consequence of the proposed change. When the change has been made, we should be able to run 20 per cent more cars to a train, the speed of the trains will be increased from 16 to 18 per cent, and the number of trains that can be sent out in any given time will likewise be largely increased, thus enabling the company to handle more traffic, and handle it more expeditiously and better than at present. During those hours of the day when the traffic is light our trains now run on some of the lines on a six-minute headway; when the proposed change is made we will be enabled to run cars without any additional expense on a headway of a minute and a half, thereby enabling persons who will not now risk waiting for four or five minutes for a train to travel by our road, induced thereto by rapid and expeditious service."

The circular mentions as additional advantages to be derived from the equipment of the elevated roads with electricity, the ease with which cars can be handled at terminal points, the better lighting of cars and stations, the operation of passenger elevators at the principal stations and the running of open cars in summer.

The circular continues in substance: "I repeat that after careful and deliberate consideration, the board of directors and executive officers concur in the opinion that the proposed change, by reason of the decreased operating expenses, the increased carrying capacity of the road, and the comfort and convenience of passengers, is one which ought not to be longer delayed

"In order to provide the means for making the change, the directors have concluded, as the best method, to create and issue $18,000,000 par value of additional stock, first to be offered to the stockholders at par.

"This will be issued, in order to provide for the necessary new plant and equipment and to modernize all facilities for the comfort and convenience of the public, thereby increasing the efficiency and economy of the service, as well as the earning capacity of the system.

"Stockholders will be given the right of taking the new stock at par on the basis of 60 per cent of their holdings, concerning which further communication will be made to the stockholders at an early date." (Signed) George J. Gould, President.

It is interesting in connection with the above circular to notice some of the bills introduced into the City Council and the Board of Aldermen within the past few weeks, and which have as their object the regulating or improving of the service on the elevated railways of Greater New York. Among these are two which were passed on Feb. 22, one requiring all elevated roads in Manhattan and Brooklyn to put drip-pans under their entire structures (over 170 miles of single track), and the other compelling the Manhattan Elevated to run at least one train every five minutes, day and night, in the Borough of Manhattan. In addition to these, bills have been introduced compelling the Manhattan to inclose all its station platforms, and to run express trains every fifteen minutes, made up of vestibuled parlor cars with reclining chairs and Welsbach gas lamps, the fare to be three cents, and the penalty for violating the ordinance $1,000; also one prohibiting the storage of cars on elevated structures. In addition to all these, the Park Board has ordered the Manhattan Railway Company to remove its elevated structure from Battery Park.

LEGAL NOTES AND COMMENTS*

Edited by J. Aspinwall Hodge, Jr., and Robert Ernest, of the New York Bar

Liability to Linemen for Accidents

Accidents to linemen and repair crews whose duties call them to the top of poles and ladders must necessarily be frequent, and when they happen the liability of the railroad company as between master and servant is involved. A recent case in New York is typical and suggestive and its facts are closely analogous to facts which must constantly arise. *Gibbons* vs. *Brush E. I. Co.* There an electric light company, after finding that the arc lights on its poles in one or two instances, between Fourteenth and Thirty-fourth Streets, on Broadway, in New York, had become insecure, ordered a new set of fastenings and hoods, and when these were obtained sent out a foreman with the plaintiff as one of his men to set them up.

Upon removing one of the old lights and while acting under the directions of his foreman, the fastenings gave way and he fell from the top of the pole, and was seriously injured. The accident occurred because of the way the plaintiff removed the light, in accordance with the foreman's instructions.

The Appellate Division of the first department held that these facts established the proposition that the accident occurred through the negligence of the foreman, who was acting as a co-employee of the plaintiff, when he gave the order which the plaintiff obeyed, and therefore the defendant was not liable.

The risks assumed by an employee are stated to be not only the risks incurred in the handling of lamps in perfect order, but in handling damaged equipment. This is in accordance with cases where the same rule has been applied to the handling by employees of defective cars where it was necessary to couple them so that they might be removed from the track in use. *Arnold* vs. *Canal Co., 125 N. Y., 15; s. c. 25, N. E. 1064. McCosker* vs. *R.R. Co., 84 N. Y., 77.*

According to the opinion of Appellate Division in this case, where a lineman is employed to assist in repairing electric lines, and in the removal of the lamps, hoods and frames, he is bound to assume that they may be defective and to govern his actions accordingly. H.

CHARTERS, ORDINANCES AND FRANCHISES

ALABAMA.—Injunction Restraining Trespass—Remedy at Law—Electric Railway—Additional Servitude.

1. Where a street railway was not authorized to extend its line on a street the fee of which was owned by another company, such company cannot restrain such proposed extension, since it is merely a threatened private trespass, which may be adequately compensated at law.

2. It is only where a party authorized by law to exercise the right of eminent domain proceeds to take property without compensation that equity will enjoin such act, without reference to the question of irreparable injury or the adequacy of legal remedies.

3. The operation of an electric railway with municipal consent along a public street, conforming to its grade, is not an additional servitude outside the public easement, for which the owner of the fee of the street is entitled to compensation.—(Birmingham Traction Co. *et al.* vs. Birmingham Ry. & Elec. Co., 24 So. Rep., 502.)

ALABAMA.—Street Railroad Corporations—Implied Powers—Eminent Domain—Contest of Corporate Right to Hold Real Property—Contracts—Consideration—Specific Performance.

1. From the naked power to construct a street railroad no authority can be derived to construct a freight belt railroad in and around a city, solely to transfer freight cars to and from factories and other railroads.

2. If any power of condemnation can be implied from the authority to construct a street railroad, it is limited to its right of way and necessary structures incident to its business.

3. A corporation authorized to construct a street railroad has no authority to receive, by condemnation or grant, property for a freight belt railroad which it had no power to construct and operate.

4. Where it has acquired title and possession, a corporation's right to hold real property can in a direct proceeding be questioned by the State only.

5. An interested individual may contest the claim of a corporation where it seeks the necessary aid of equity to perfect title to real property, but not where a deed has been executed and delivered or the consideration paid, or the question involved is not the right of the corporation to hold property of a particular kind or for a particular purpose, but its right to hold property in excess of a definite quantity or value.

6. Where a railroad granted the right to use its right of way to a corporation unauthorized to take such a grant, the grantee's successor, though not incapacitated, could not secure the aid of equity to perfect its title to, or obtain possession of, the property, unless the grantor has acted so as to estop himself from denying the successor's right under the agreement.

7. The performance of acts required by statute to be performed does not constitute a valid consideration for a contract.

8. A railroad company, under the mistaken supposition that a land company was authorized to construct a railroad and condemn a right of way across its tracks, and to prevent the land company's threatened crossing of its tracks at inconvenient points, granted the land company the right to cross at certain other points, and to use a certain part of its right of way. The land company's undisclosed object was to secure a right of way into the railroad company's passenger station, under the mistaken belief that it was legally entitled to enter and use the same, and that it owned and could cross a certain 35-ft. strip of land in doing so. In consideration therefor, the land company was to repair the crossings, pay for erecting and maintaining signals and employing watchmen thereat, and grant to the railroad company the privilege of crossing and building its tracks on the 35-ft. strip of land it was supposed to own. Possession of its grant was never acquired by the land company, or its successor, further than to lay a part of its track, which was subsequently occupied by other railroads for passenger traffic, with the railroad company's permission. This traffic, if the agreement was enforced, would be interrupted, to the great injury of the railroad company and the interests of the public; but neither the land company nor its successor, seeking to enforce the agreement, were legally authorized to construct railroad tracks over the right of way leading to the passenger station, and which the agreement was intended to secure. Held, that specific performance of the agreement would not be enforced.—(South. & N. A. R. Co. vs. Highland Ave. & B. R. Co., 24 So. Rep., 114.)

MICHIGAN.—Location—Jurisdiction.

Where the power to locate the road of a street railway through a township is conferred by statute upon the supervisor and highway commissioner, courts have no power to review their action.—(Silsley *et al.* vs. Lyle, commissioner of highways, 75 N.W. Rep., 886.)

MINNESOTA.—Car Barn—Nuisance.

1. The defendant has for some years maintained and operated by public authority a street-car system, the motive power of which is electricity, in the city of St. Paul. As a necessary incident to such operation it has maintained a car barn in a residence district, for the purpose of storing a part of its cars when not in use on the streets. The barn fronts on Ramsey Street, with its sides abutting on Thompson and Smith Avenues, respectively. It is not authorized to operate its system on these avenues, but it has, without any negligence in the premises, laid tracks and curves thereon, over which it runs, from early in the morning until late at night, its cars to and from the barn. Such operation of its cars over such tracks and curves causes loud and disagreeable noises, whereby the rest and comfort of the plaintiff are disturbed, and the rental value of his real estate abutting on the street and avenues is materially reduced. Held, construing the city ordinances granting to the defendant the right to operate its street-car system, that it is authorized to so lay and operate the tracks and curves on the avenues.

2. Held, further, upon the undisputed evidence, that the location of the barn is not an improper or unreasonable one, and that the acts of the defendant do not constitute a private nuisance for which the plaintiff can recover damages.—(Romer vs. St. Paul City Ry. Co., 77 N. W. Rep., 825.)

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

MISSOURI.—Franchises—Public Sale—Construction of Statute—Vagueness—Impossibility to determine Meaning.

1. Act, April 9, 1895, provides that the municipal authorities to whom application may be made for consent to the construction, extension, maintenance, occupation, or use of, inter alia, any street railway or railroad for the transportation of freight, passengers, or mails, must provide, as a condition precedent to the granting of such consent, that the franchise shall be sold at public auction to the responsible bidder who will give the largest percentage yearly of the gross receipts derived from such occupation and use, with adequate security for the payment thereof, and for the prompt construction and completion of the proposed plant, provided that such payment shall in no case be less than 2 per cent of the gross earnings uring the first five years of said occupation and use, and thereafter for each period of five years such percentage shall be increased to correspond with the increase in value of the land thus occupied and used. Held, that the act is void, in that its meaning cannot be determined by any known rules of construction, because, if it means that the company must pay at least 2 per cent of its gross earnings for the first five years to each municipality over whose streets it may build, and to each county whose highways it may cross, the railway company may in many cases be compelled to pay more than its total receipts.

2. It is also void if it means that the percentage should be computed only on the gross receipts of that part of the road located on the streets of the city or across the highways, as the case may be, because there is no method provided by which the actual gross receipts of that particular part of the road can be ascertained.

3. A continued line of railroad cannot be subdivided so as to permit competition for the privilege of constructing and operating separately the portions thereof lying within the municipalities and across the highways on its route.

4. The act cannot be practically enforced, since, in the case of street railroads, there is nothing to show on what gross earnings the percentage is to be computed, the act evidently contemplating that the bid shall be a percentage only of the receipts derived from the use and occupation of the "public" property, and a portion of the earnings being attributable to the capital invested in power stations, machinery, etc.

5. The percentage is to be increased in "each period of five years to correspond with the increase in the value of the land thus occupied and used," but the act gives no intimation by whom or in what manner this increase is to be settled and determined.

6. If the provision for increased payment for the franchise after five years is meaningless, in the case of street railroads, the proviso is practically eliminated, so that it is highly improbable that the Legislature would have passed the act with the clause increasing the percentage in each term of five years omitted.—(State *ex rel.* Crow, Atty.-Gen., vs. West Side St. Ry. Co., 47 So. W. Rep., 959.)

NEW HAMPSHIRE.—Incorporation—General Law—Additional Routes—Public Good.

1. Laws 1895, c. 27, sec. 3, providing for the organization of street railway corporations by general law, and authorizing the court to determine whether the public good requires a proposed street railway corporation to build on a proposed route, does not authorize the courts to determine whether the public good requires a street railway corporation organized by a special law before said chapter was passed to build on a proposed route that is not an extension of its road, which, by the act incorporating it, it was authorized to build.

2. A street railway corporation incorporated under a special law prior to the passage of Laws 1895, c. 27, providing for incorporation by general law, need not procure a reincorporation under the general law; section 1 providing that the specially chartered companies shall continue to exercise the powers granted by their charters except as modified by said chapter.—(*In re* Keen Electric Ry. Co., 41 Atl. Rep., 775.)

NEW YORK.—Greater New York Charter—Street Railway Franchise—Legality of Municipal Grant—Certified Questions.

1. Laws 1897, c. 378, sec. 73 (Greater New York Charter), providing that, "after the approval of this act," no franchise or right to use the streets, avenues, parkways, or highwas shall be granted by the "municipal assembly" for a longer period than twenty-five years, etc., became operative on May 4, 1897, the date of the approval of the act, and applied to the board of aldermen then in office of the city of Brooklyn, notwithstanding its reference to the "municipal assembly," which was not to come into existence until January 1, 1898.

2. A perpetual charter, granted by the authorities of Brooklyn after the approval of the Greater New York Charter, to a street railway, is not valid as a charter for twenty-five years.

3. Where a case is sent to the Court of Appeals on special questions otherwise not reviewable, the questions should be so framed that the answers may determine the particular controversy involved in the appeal, and not merely a part of it.—(Blaschko vs. Wurster, Mayor, *et al.*, 51 N. E. Rep., 303.)

NEW YORK.—Mandamus—Peremptory Writ.

A peremptory writ of mandamus is issued in the first instance only in case of a clear legal right on uncontested facts.—(*In re* Forty-second M. & St. N. Ave. Ry. Co. vs. Collis, 53 N. Y. Suppl., 669.)

NEW YORK.—Construction and Operation—Consent of Abutters.

Laws 1839, chap. 218 (re-enacted as Laws 1890, chap. 565, sec. 78), providing that any railroad corporation may contract with any other railroad corporation for the use of their respective roads and thereafter use the same in such manner and for such time as may be prescribed in the contract, is not in conflict with Const., art. 3, sec. 18, providing that no law shall be enacted permitting street railroads to construct their lines without first obtaining the consent of the owners of one-half in value of the abutting property; or with Laws 1890, chap. 565, sec. 91, as amended by Laws 1896, chap. 855, providing that a street railroad or extensions or branches thereof shall not be built or "operated" unless the consent of abutters is obtained; or with Id., sec. 102, providing that no street-surface railroad shall construct, extend, or operate its tracks in that portion of a street where such a road is already constructed without consent of the other road, but that the two railroads may unite in the use of tracks on the condemnation thereof in the manner prescribed for the benefit of one of the companies. Hence consent need not be obtained by a street railroad company operating under a contract over a portion of another company's tracks.—(Ingersoll vs. Nassau Elec. R. Co., 52 N. E. Rep., 545.)

NEW YORK.—Conversion—Removal of Electric Wires—Damages.

1. Though the erection of wires on housetops, the householders consenting, be illegal, the city is liable for conversion where, without offering the owner a reasonable opportunity for reclaiming them, it cuts down the wires and carries them away.

2. It is no defense that the value of the wire could not be accurately determined where the evidence tended to show the wire to be worth a certain sum per foot.—(Electric Power Co. vs. Mayor, etc., of the City of New York *et al*, 55 N. Y. Suppl., 460.)

NEW YORK. — Construction—Injunction—Abutters—Extension—Validity—Municipal Consent—Retroactive Effect.

1. An abutting owner may enjoin the unauthorized construction of an electric railway in a street without showing that the benefits from the railway will not offset the injuries.

2. A street railroad company, whose articles contemplate a single, connected road, carrying from end to end for a single fare, cannot construct an independent line, not connected with its original line, under extension proceedings.

3. Where an extension of a street railroad was invalid because it was disconnected from the line authorized in the original franchise, a second extension proceeding, providing for a line to connect the extension with the original, does not validate resolutions of municipal authorities authorizing the first extension.—(McLean vs. Westchester Elec. Ry. Co., 55 N. Y. Suppl., 556.)

TEXAS.—Trust Mortgage—Foreclosure.

Where a corporation issues a series of bonds to a trust company, and at the same time executes to it a mortgage conveying to it property to secure the payment of the bonds, and providing that, on default in the payment of the interest, the trustee may declare the entire principal of bonds due, and bring suit to foreclose, bonds of such series transferred to an individual are merged in a judgment, if obtained by the trustee in a suit to foreclose and for personal judgment for the debt evidenced by the bonds, so that such individual owner cannot thereafter maintain a suit on his bonds.—(Laing vs. Queen City Ry. Co., 49 S. W. Rep., 136.)

LIABILITY FOR NEGLIGENCE

ALABAMA.—Electric Cars—Injuries at Crossings—Negligence—Name of Motorman—Pleading—Contributory Negligence—Question for Jury—Instructions.

1. A complaint against a street railroad company to recover damages for injuries to one not an employee need not state the name of the motorman whose negligence is alleged to have caused the injury.

2. Where a driver had the right to drive across an electric railroad track at a certain point, the company is guilty of negligence in running its car at so great a rate of speed as to be unable to avoid running into him.

3. It is not negligence per se for a driver to cross over a railroad track whenever he may have occasion so to do for the pur-

pose of going from one side of the street to the other, whether in the open country or in the limits of a city or village.

4. Where an electric railroad company was negligent in running its car at such a speed that it could not stop it in time to prevent hitting a horse which had balked on the track, assuming that the driver's failure to attempt to back the horse off the track was equivalent to permitting it to remain on the track, it is for the jury whether such act contributed to the injury.

5. An instruction assuming as a fact a matter not proven is erroneous.

6. An act of contributory negligence not charged in the answer cannot be made the basis of an instruction.

7. An instruction that if an ordinarily prudent person would not have tried to pull the horse forward as the plaintiff did, but would have backed him off the street-car track, the verdict must be for defendant, is properly refused, as assuming that an effort to back the horse off the track would have been successful.—(Birmingham Ry. & Elec. Co. vs. City Stable Co., 24 So. Rep., 558.)

CALIFORNIA.—Collision with Street Car—Negligence and Contributory Negligence—Question for Jury—Instructions.

1. Evidence for plaintiff showed that, just before driving his wagon across defendant's street-car track, he looked and listened, but did not see an appraching car until he was nearly on the track. The car was then about 50 yds. away, and he could have crossed, if those in charge, after he called to them, and after they saw him, had lessened its speed, as they could have done. Owing to obstructions he could not see the car, or be seen by those in charge of it, until he reached the street from an adjoining lot. Held, that the question of contributory negligence was for the jury.

2. Evidence showed that the defendant's street car was traveling faster than the prescribed limit, and there was evidence that those in charge, after they discovered plaintiff on the track with a wagon, could, with ordinary diligence, have stopped the car before it reached him; and plaintiff testified that the car was 50 yds distant from the crossing at the time he was discovered by those in charge of the car. Held, that the question of defendant's negligence was for the jury.

3. An instruction, in an action for injury to a person crossing the track, that a street railroad has only an equal right with the traveling public to the use of the street whereon its track is built, was not improper because omitting some few exceptions not material in the case, such as that when an ordinary vehicle meets a car on its track it must give way to the car.

4. There is no error in refusing an instruction sufficiently included in instructions given.—(Clark vs. Bennett, 5 5Pac. Rep., 908.)

INDIANA.—Carriers—Injury to Passenger Riding on Platform—Contributory Negligence—Directions of Conductor—Damages—Pleading—Variance—Questions for Jury—Instructions—Depositions—Appeal.

1. Whether a passenger in a street car is negligent in giving his seat to a woman and riding on the platform, at the general request of the conductor, is for the jury.

2. There is no variance where the evidence fairly tends to prove the substance of the issue.

3. Where the testimony is conflicting, and there is evidence which fairly tends to support the verdict, the judgment entered thereon cannot be disturbed on appeal.

4. A request by a conductor of a street car for a passenger to ride on the platform amounts to a direction to ride there.

5. Under an allegation that plaintiff rode on the platform of a street car at the request of the conductor, and was injured through the negligence of the company's servants, plaintiff may recover without proving that the conductor requested him to ride on the platform.

6. A refusal of an instruction that plaintiff could not recover for fright, suffering, and nervous shock, unless they were the result of the "bodily injuries" received, is not error, where an instruction was given that there could be no recovery for such injuries, unless they were the result of "personal injuries" received.

7. Where instructions, taken as a whole, state the law correctly, and are not misleading, the case will not be reversed for inaccuracies of expression in some of them.

8. Where a witness whose deposition had been taken testified in person, and the opposite party introduced a portion of his deposition to impeach him, the party taking it might introduce the entire deposition, although it did not all bear on the subject matter of the impeachment.—(Terre Haute Elec. Ry. Co. vs. Lauer, 52 N. E. Rep., 703.)

INDIANA.—Pedestrians—Contributory Negligence.

A passenger got off a moving street car before it reached a crossing, and, without stopping to look, walked rapidly behind the car to cross the street and walked against the side of a car coming from the opposite direction, on a track five feet distant from the other. This car had its lights lighted, and could have been readily seen, except as the view was obstructed by the other car. Held, that he was negligent.—(Stowers vs. Citizens St. R. Co., 52 N. E. Rep., 710.)

INDIANA.—Personal Injuries—Action by Administrator—Abatement—Statutes—Appeal.

1. Where the Legislature re-enacts a statute of the State it adopts also the construction given thereto by the courts of the State before the re-enactment.

2. Under Burns' Rev. St., 1894, sec. 283 (Horner's Rev. St., 1897, sec. 282), providing that causes of action arising out of an injury to a person die with the person, except actions given for an injury causing the death of any person, an administrator cannot sue for damages for physical pain and suffering of intestate, since the right of action abates.

3. By failing to discuss an assignment of error appellant waives the error.—(Hilliker vs. Citizens St. R. Co., 52 N. E. Rep., 608.)

KENTUCKY.—Carriers—Injury to Passenger in Alighting from Street Car—Instructions to Jury.

1. In an action to recover damages for injuries to a passenger in alighting from a street car it was error to refuse to instruct the jury that the law made it the duty of defendant's agents and servants operating the cars "to observe the utmost care and skill which a prudent man would exercise under like circumstances in the management and control thereof while she was alighting therefrom, and to afford her reasonable opportunity to alight in safety."

2. It was error to give an instruction requiring the jury to believe, in order to find for plaintiff, that the negligence of defendant caused all the injuries to plaintiff complained of; it being doubtful, from the evidence, whether some of the injuries resulted from defendant's negligence.—(Lutz *et ux.* vs. Louisville Ry. Co., 48 S. W. Rep., 1080.)

LOUISIANA.—Weight of Evidence—Carriers—Injury to Passenger.

1. In case the positive statements of two witnesses are exactly in opposition to those of two other witnesses—said witnesses testifying on different sides of a cause, and all of them being equally entitled to credit—the physical situation of the rest may be treated as having the effect of turning the scale.

2. If a passenger, in alighting from an electric car at point of destination, is thrown to the ground by the suddenness with which same is either stopped or started, and this result is caused or contributed to by those in charge of same, a case of negligence of the railroad company is made out, for which it must respond in damages.—(Bourque vs. New Orleans City & Lake R. Co., 24 So. Rep., 622.)

NEW JERSEY.—Death by Wrongful Act—Elements of Damage—Excessive Verdict.

1. In an action based upon the act entitled "An act to provide for the recovery of damages in cases where the death of a person is caused by wrongful act or neglect," approved March 3, 1848, the plaintiff is entitled to recover nothing but the pecuniary loss sustained by the person for whose benefit, as next of kin, the action is brought.

2. Where the deceased was a boy fifteen years of age, with an earning capacity of about $20 per month, and the cause was tried on the basis that the pecuniary benefit to the father could only continue during the minority of his son, if his life had continued, and the instructions of the trial court were to that effect, held, that a verdict of $3,000 was excessive, and that, as the verdict of the jury was based upon only a misapprehension of the instructions of the court as to the measure of damage, the plaintiff could have the option of accepting the sum of $1,500; otherwise the verdict be set aside and a new trial ordered.—(May vs. West Jersey & S. R. Co. *et al.*, 42 Atl. Rep., 165.)

NEW JERSEY.—Wrongful Death—Elements of Damage—Services of Wife.

1. In an action under the death act (1 Gen. St., p. 1188), where it is contended that the advice and counsel of the deceased to the next of kin is an element of damage, it must be shown by the facts and circumstances that such advice and counsel would relate to the pecuniary affairs of the next of kin, and that such advice and counsel would probably result in a pecuniary benefit, and that by the deprivation of such advice and counsel a pecuniary injury would accrue.

2. The services of a wife in her husband's household in the ordinary work thereof, or in aiding and assisting him in his occupa-

tion is due and belongs to the husband; and her continued services during the life of her husband cannot be a pecuniary benefit to the next of kin, and the deprivation of such services cannot be a pecuniary injury, nor afford ground of recovery of damages under the death act of this State. Whether such services after the death of her husband would be a pecuniary benefit to the next of kin is a question too remote to be considered by the jury as a basis of a verdict of damages under such act.—(May vs. West Jersey & S. R. Co. *et al.*, 42 Atl. Rep., 163.)

NEW JERSEY.—Injury to Passenger—Question for Jury.

A boy twelve years of age was about to take passage on an open electric street car, having a bar across the side next to an adjoining track. Under the conductor's eye, he stepped upon the footboard at the barred side, and, before he was fairly on, the car was started on the conductor's signal, and the boy was thrown down and injured. Held, that the question of the conductor's negligence and of contributory negligence in the boy were for the jury, and that a nonsuit was wrong.—(Kelly vs. Consolidated Traction Co., 41 Atl. Rep., 686.)

NEW JERSEY.—Injury to Person on Track—Contributory Negligence.

The plaintiff, at a little after 9 o'clock on a dark night, was approaching on foot a trolley road having a single track, which he intended to cross. His line of approach was northwesterly, and diagonal to the track. When he had somewhat more than 50 ft. to walk before crossing the track, he saw a car somewhat more than 250 ft. south of the place of crossing. He testified that, when from 4 to 6 ft. distant from the track, he turned his head, looked for the car south along the track 75 or 100 ft., and did not see it; that he was then going diagonally across; that the first thing he knew the car was on him, and knocked him down; and that he was about the middle of the track when he was struck. The track to the south was straight for more than 250 ft. and the view of it was unobstructed. It is to be assumed that the plaintiff moved at the rate of an ordinary walk. Three witnesses observed and testified as to the car's rate of speed. Held, that facts within the plaintiff's knowledge and observation made it probable that the car, coming from a quarter towards which his back was partly turned, would be dangerously near to him before he got across the track; that it was therefore his duty to look for the car before he attempted to cross; that the car, moving at any rate of speed that is attributable to it under the evidence, must have been so near to the plaintiff when he looked for it before going on the track that, if he had not looked carelessly, he would have seen it, and have been warned of imminent danger; that his failure to receive warning was therefore due to his own negligence, and that the nonsuit was properly granted.—(Jewett vs. Patterson Ry. Co., 41 Atl. Rep., 707.)

NEW YORK.—Joint Tort Feasors—Stipulation not to Collect from One.

A stipulation not to collect from one joint feasor who agrees not to exact costs, will not discharge a judgment against a co-defendant. To discharge all joint tort feasors, the instrument must be a technical release under seal.—(Schramm vs. Brooklyn H. R. Co. and Consolidated Ice Company. Appellate Division, second department, Dec. 14, 1898.)

NEW YORK.—Joint Tort Feasors—Dismissal of Action against Co-Defendant—Street Railway Company—Injury to Passenger—Evidence—Question for Jury—Boarding Moving Car—Contributory Negligence—Instructions—Corroboration of Plaintiff by Defendant's Witnesses—Death by Wrongful Act—Damages.

1. A joint tort feasor cannot complain of the dismissal of the complaint as to his co-defendant.

2. Where the evidence on the part of plaintiff tended to show that defendant's car, as it approached a crossing, was brought nearly or quite to a stop to allow plaintiff's intestate to step aboard; that, after he had partially entered, the car, without any notice to him, was suddenly started with a jerk, throwing him to the ground, causing the injuries complained of—it was not error to refuse to dismiss.

3. It is not error to refuse to dismiss where plaintiff's evidence shows that the injuries complained of were caused by negligently starting the car with a jerk after her intestate had boarded the same, and defendant's evidence shows that he fell before reaching the car.

4. Attempting to enter or leave a moving street car is not contributory negligence per se.

5. A request to charge that, if the accident happened as testified to by defendant's witnesses, the verdict should be for defendant, is properly refused, where the testimony of some of such witnesses tends to corroborate plaintiff's witnesses.

6. A verdict of $9,000 is not excessive where deceased, at the time of his death, was forty-three years of age, in good health, received a salary of $1,250 a year, and left five children, who had been dependent upon him for support.—(Wallace vs. Third Av. R. Co. *et al.*, 55 N. Y. Suppl., 132.)

NEW YORK.—Injury to Person on Track.

Plaintiff's intestate, while playing with other boys in a street on which were two street railway tracks, started to run across the street near the middle of a block. He passed in the rear of a car going north, but, seeing a car coming south at a rapid rate on the other track, he stopped between the tracks, then suddenly attempted to cross the other track, and was struck by the southbound car. Held, that there was no proof of negligence on the part of defendant's servants.—(Greenberg vs. Third Ave. R. Co., 55 N. Y. Suppl., 135.)

NEW YORK.—Dismissal—Evidence—Construction—Electric Road—Speed—Testimony—Negligence—Statute—Court and Jury.

1. On an appeal from a dismissal the evidence must be construed on all doubtful questions in favor of the plaintiff.

2. Testimony of a high rate of speed of an electric car may be accepted by the jury where there is nothing in the evidence showing it to be incredible.

3. There is no statutory rate of speed for a car in New York city, and negligence, as a matter of law, can be laid down only in extreme cases.

4. Whether a street car is running at a dangerous speed in any locality, is ordinarily, a question for the jury.—(Fullerton vs Meteropolitan St. Ry. Co., Supreme Court, Appellate Division, First Department, Feb. 10, 1899.)

NEW YORK.—Imputed Negligence—Driver of Vehicle—Collisions—Appeal—Harmless Error—Instructions—Special Damages—Pleading and Proof.

1. The contributory negligence of a driver of a carriage which occasioned a collision with a street car cannot be imputed to a person in the carriage, where the driver was not subject to his direction.

2. A mistaken statement of the court that it had charged that plaintiff might recover if the collision with defendant's street car occurred as described by plaintiff's witnesses is harmless where such charge would have been correct.

3. Where plaintiff alleged that a nervous shock was occasioned by injuries, evidence that she suffered from curvature of the spine is not inadmissible as constituting special damages not pleaded, if there is evidence that such curvature was caused by the nervous shock.—(Kleiner vs. Third Av. R. Co., 55 N. Y. Suppl., 394.)

NEW YORK.—Rights of Pedestrians—Contributory Negligence—Accidents at Crossings—Instructions—Care Required in Operation.

1. A person is not at liberty to take even doubtful chances of being able to cross a street in front of an approaching car, or to assume that the motorman will be able to successfully stop it.

2. In an action for damages for being run into by a street car, an instruction that plaintiff is chargeable with negligence if he saw the approaching car and did not take "proper steps" to avoid it, and that he was not at liberty to take even doubtful chances in attempting to cross the street in front of the car, is not erroneous by reason of the use of the term "proper steps," since, construed as a whole, it only requires reasonable care.

3. The degree of care required in operating a street car is to be reasonably careful, to keep the car under proper control, and to be vigilant in approaching crossings.—(Harvey vs. Nassau Electric R. Co., 55 N. Y. Suppl., 20.)

NEW YORK.—Master and Servant—Personal Injuries—Proximate Cause—Fellow Servants.

1. An injury caused to a carpenter by being knocked down from a ladder by a loose horse and cart striking it was not proximately caused by the absence of a vice principal who was to guard the ladder against passing carts or cars.

2. A driver of a cart removing rubbish from a building under construction is a fellow servant of a carpenter on a ladder, the foot of which was near a door where the cart had to pass.—(Byrnes vs. Brooklyn Heights R. Co., 55 N. Y. Suppl., 269.)

NEW YORK.—Injury to Passenger—Contributory Negligence.

Under a complaint alleging that plaintiff was injured while attempting to board a car which had stopped to receive him and was suddenly started, it was error, where the evidence as to whether the car had stopped or not was conflicting, to refuse an instruction that if the car did not stop, but, while moving, plaintiff attempted to board it, and was injured, the verdict must be for defendant.—(Anderson vs. Third Ave. R. Co., 55 N. Y. Suppl., 290.)

NEW YORK.—Carriers of Passengers—Negligence—Joint Tort Feasors—Appeal—Reversal—Measure of Care and Skill—Appeal — Review — Instructions —Witnesses — Bias — Evidence —Harmless Error—Competency—Physicians—Damages—Materiality—Pleading—Amendment—Discretion.

1. A passenger of a horse car having been injured in a collision between it and a cable car, the horse-car company was not relieved of liability by the fact that its car had the right of way, where the cable car was moving toward the crossing at a rapid rate, and there was no appearance of any disposition to check speed before it reached that point.

2. Where a passenger sued the respective owners of colliding street cars for injuries, neither defendant was entitled to an instruction as to the negligence of the other, further than that each of the persons in control of the cars had a right to assume that the other would not proceed over the crossing negligently.

3. In an action against joint tort feasors, wherein plaintiff recovered, either defendant is entitled to a reversal if the charge was erroneous as to him, though it was given at the request of his co-defendant.

4. A horse-car company is bound to exercise all the care and skill which human foresight can suggest to secure the safety of a passenger at a cable-car crossing.

5. The court will not reverse for technical error in a charge disposing of forty-three requests made by defendants, when the charge as a whole is fair and correctly expounds the law.

6. In an action for personal injuries, wherein plaintiff's father testifies in her behalf, his bias may be shown by evidence that he has sued for loss of her services.

7. Where the testimony in an action for personal injuries showed that witness was plaintiff's father, and the jury were informed that he might sue for loss of her services, error in rejecting evidence of that fact to show witness' bias was harmless.

8. When a patient waives the privilege a physician may be compelled to testify to matters concerning the professional relation.

9. In an action for personal injuries evidence of the cause of peritonitis, from which plaintiff suffered before the accident, is properly rejected, where it does not appear to be material and counsel do not state what they expect its bearing will be.

10. It is in the discretion of the court to permit a complaint for personal injuries to be amended on the trial so as to ask $50,000 instead of $10,000.—(Zimmer vs. Third Ave. R. Co. *et al.*, 55 N. Y. Suppl., 308.)

NEW YORK.—Passengers—Alighting from Moving Car.

A passenger on a street car signaled the conductor to stop the car, and, as it was slowing down, he prepared to get off and was injured by the gripman suddenly increasing the speed of the car. Held, that he could not recover in the absence of proof that the conductor signaled the gripman, since the latter may have slackened the speed in the exercise of reasonable care in the operation of the car.—(Armstrong vs. Metropolitan St. Ry. Co., 55 N. Y. Suppl., 498.)

OHIO.—Damages—Personal Injury to Child—Impairment of Prospects of Marriage—Pleading—Special Damages—Setting Aside Verdict—Excessive Damages—Province of Court and Jury —Railroads—Injury to Person on Track—Trespassers—Presumption as to Rights in Street—Permitting Public to Use Track—Measure of Care Required—Contributory Negligence of Child—Negligent Handling of Cars—Injury to Children.

1. Where a personal injury to a little girl is such as to seriously impair her prospects of marriage when she reaches a marriageable age, such fact may properly be considered by the jury as an element of damages resulting from the injury.

2. While the loss of a particular prospect of marriage by a woman must be specially pleaded to entitle it to be considered as an element of damage, the loss of a general prospect of marriage, in the case of a child by reason of an injury which disfigures her, is a natural, and not a special, consequence of the injury, and may be, and in fact can only be, taken into consideration as an element of general damages, and a special allegation with regard to it is not required.

3. A verdict should not be set aside simply because it is excessive in the mind of the court, but only when the excess is shocking to a sound judgment and a sense of fairness to the defendant. Where there is any margin for a reasonable difference of opinion in the matter, the view of the court should yield to the verdict of the jury, rather than the contrary.

4. Where a railroad occupies a street with its tracks the ordinary presumption is that of a joint use by the public and the railroad company; and although the municipal authorities may, under the statute, have power to grant the exclusive right to the use of the street to the railroad company, in the absence of proof of such grant, or of the exclusive use of the street by the company for such a length of time as to give it the right by prescription, a person injured upon the track in the street cannot be regarded as a trespasser.

5. Even where the track of a railroad is on its private property, if it permits the public, including children, to habitually cross its track at a given point without objection, it is bound in the operation of its trains to exercise care with due regard to such probable use, and to the probable danger to persons so using the crossing.

6. While it is the duty of children to exercise ordinary care to avoid injury, ordinary care for them is that degree of care which children of the same age, of ordinary care and prudence, are accustomed to exercise under similar circumstances.

7. To permit a loaded railroad car to run down a grade alone on a track laid in a street, without the exercise of any care or attention to see that no children are in danger therefrom, constitutes negligence which renders the railroad company liable for the injury of a child too young to take care of itself, which was on the track without the fault or negligence of its parents.—(Smith vs. Pittsburgh & W. Ry. Co., 90 Fed. Rep., 783.)

PENNSYLVANIA.—Accident—Negligence—Evidence.

The questions of negligence and contributory negligence are for the jury; there being evidence that a boy on a street car intended and attempted to get off at a certain street crossing, but was prevented from doing so by the car not stopping long enough, and the evidence being conflicting as to whether he was jolted from the car, or fell off or jumped off; he having in some way got off and under the car between that and the next street.—(Moran vs. Versailles Traction Co., 41 Atl. Rep., 652.)

PENNSYLVANIA.—Trolley Cars—Excessive Speed—Evidence.

Verdict should be directed for defendant in an action against a street railway company by one whose horse was frightened by a trolley car, the negligence alleged being the excessive speed of the car, and his testimony that it was "not less than 15 miles an hour," being a mere guess, and his further testimony that not till the car was alongside the horse did it turn into the gutter, and that it then backed against the car, showing, as testified by defendant's witnesses, that the car was running slowly.—(Smith vs. Holmesburg T. & F. Elec. Ry. Co., 41 Atl. Rep., 479.)

PENNSYLVANIA.—Injury to Passenger—Negligence.

A street railway company is liable to a passenger who, without any contributory negligence, following the invitation and direction of the motorman, leaves the car from the front door, on a dark night, and where the ground was broken, and, after taking a few steps, catches her feet in some way, and falls.—(41 Atl. Rep., 743.)

TENNESSEE.—Injury to Employee—Vice Principal—Contributory Negligence—Assignment of Error.

1. Assignment of error that the verdict is "against the charge" is superfluous, there being one that it is against the evidence.

2. It is not negligence as matter of law for one working under a track foreman to attempt at command of the latter, to board a train, consisting of a flat car and trolley car, while going at the rate of 3 or 4 miles an hour.

3. A track foreman who is at the time running a trolley car and flat car attached, carrying tools and materials to a point on the road, and is controlling the cars, and is in charge of the motor as conductor, is a vice principal as regards his negligence in ordering one of the track hands to board the cars while in motion, or in failing to stop them while such employee is hanging onto the railing, which he caught hold of in his attempt to get on board.—(Chattanooga Elec. Ry. Co. vs. Lawson, 47 So. W. Rep., 489.)

Electric Railway Motor Patent Decision

The Thomson-Houston Electric Company and the General Electric Automobile Company have secured an injunction in the United States Circuit Court, Southern District of Ohio, restraining the Steel Motor Company and the Johnson Company from making or selling any combination of electric railway motors and motor circuits and resistances combined with controllers, like controllers covered by Claims 20, 21, 22, 27, 28 and 30 of Letters Patent No. 393,323. Claims 20 and 31 of this patent are as follows:

"20. The combination of a source of electric energy, the coils of one or more electric motors, a switch for connecting said coils in different ways to vary the motor resistance, one or more resistances, and a switch to put said resistances into or out of the motor-circuit without changing the motor-connections to vary the power of the current flowing through the motors.

"31. The combination of two motors, a source of electric power, a motor-circuit, a switch for coupling the coils of the motors in series or multiple to vary their internal resistance, a resistance, a

switch to insert the resistance when the motor-switch is being shifted, and a connection between said switches to operate both simultaneously."

Patent Decision in the Electric Railway Motor Suspension Case

The Sprague Electric Railway & Motor Company has been granted an injunction in the United States Circuit Court, Eastern District of New York, against the Nassau Electric Railroad Company, restraining that company from infringing Letters Patent No. 324,892, which was granted to Frank J. Sprague on Aug. 25, 1885, for improvements in electric railway motors. The claims of this patent, which the court holds were being infringed are Claims 2 and 6, and read as follows:

"2. The combination of a wheeled vehicle and an electro-dynamic motor mounted upon and propelling the same, the field magnet of said motor being sleeved upon an axle of the vehicle at one end, and supported by flexible connections from the body of the vehicle at the other end, substantially as set forth.

"6. The combination, with a wheeled vehicle, supported upon its axles by springs, of an electro-dynamic motor flexibly supported from such vehicle, and centered upon a driven-axle thereof, substantially as set forth."

This patent is owned by the General Electric Company, which controls the plaintiff company.

Commutator Bars of Tempered Copper

The tempering of copper has long been considered a lost art, but has been recently rediscovered, or, at least, a process has been devised for tempering copper and rendering it especially suitable for making solid castings for commutator bars. The secret of the process is known only to Theodore F. Frank, superintendent of the Mansfield Tempered Copper Company, Mansfield, Ohio, and this company has been engaged for the last four years in casting commutator bars of all descriptions and has now built up a trade which extends to all parts of this country and to foreign countries, shipments being made frequently to the Siemens & Halske Company, of Vienna, Austria. In the process of casting the pure copper is melted in retorts in about the same manner as is the custom in ordinary brass and copper furnaces, and when melted is treated by the secret process, and is poured quite hot into the molds. After being formed the bars are placed under a drop hammer, when they are ready for assembling, and are so accurate to size and gage that when assembled they form a perfect cylinder. The company enjoys the patronage of a large number of the manufacturers of generators and motors throughout this country and Europe, and makes patterns of special designs to suit its customers. It has now in stock patterns of more than 2500 different styles of commutator bars. These are kept in suitable cases and all the different types belonging to any electric company have a special compartment and are labeled with the name of the company. The company not only manufactures bars, but has recently engaged in the manufacture of assembled commutators for street railway motors. These are turned up and finished for any of the standard types of motors, all ready to be put in service.

In the manufacture of commutator bars the works consume about ten tons of copper per month, and the bars are made from all sizes from those so small that it requires thirty-five or more to the pound, up to single bars weighing from 5 lbs. to 6 lbs. each. In the manufacture of the large size bars the groove for the connections is cored out, which saves milling, and when so ordered, bars are cored without extra charge. The works have been enlarged two or three times since they were first established, and now fifteen molders are employed in making bars.

The patterns for these are duplicated and formed in nests of six or more, so that a number of bars are formed at one pouring. The equipment of the foundry is very complete, being up to date in every respect. The company not only manufactures commutator bars, but also makes brass castings of almost every description and babbitt journal bearings. The rapidly increasing trade of the concern is due to the fact that the products, especially the commutator bars, are superior in material and finish, being dense, entirely free from blow-holes, smooth and accurately finished.

Power for operating the drop hammers and emery wheels is derived from an electric motor of the card type, the current for operating the same being derived from the plant of the Card Motor Company, which adjoins that of the Tempered Copper Company.

The affairs of the company are operated under the direction of S. N. Ford, president, and S. Glen Vinson, secretary, while, as noted above, Theodore F. Frank superintends the work in the foundry. Mr. Frank has had twenty-five years' experience in general foundry business, and over ten years in the manufacture of tempered copper, so that he is well fitted for making castings of every description from copper or brass.

NEWS OF THE MONTH

Perhaps one of the most interesting features of the new passenger station of the New York, New Haven & Hartford Railroad at Boston, is the electrical switching apparatus for handling the 750 trains that pass through the station daily. To connect the station sidings with the main track, there are fifty-two single switches, thirty-five double slip switches and thirty-five movable frogs, and any one of these can be thrown by simply pressing a button in the switching tower.

It is stated that the syndicate headed by Alexander Brown & Sons of Baltimore, which has recently secured control of all the street railway properties of the city, has also purchased all the electric lighting companies of Baltimore.

It is expected that 60 miles of electric railway will soon be built in the island of Porto Rico by a Massachusetts concern, known as the International Construction & Power Company. This company will have a capital stock of $5,000,000, and a number of the incorporators are prominent Massachusetts citizens. Among the largest holders of stock in the new venture are the Hon. E. P. Shaw, State treasurer, and his two sons, E. P. Shaw, Jr., and James F. Shaw.

Part II. of the 1899 report of the Board of Railroad Commissioners of Massachusetts has just been issued. The report contains the returns of the street railway companies of that State for the year ending September 30, 1898, and from it the following statistics are taken. The figures for 1897 are also given herewith for the sake of comparison.

	1897.	1898.
Gross receipts	$15,898,839	$18,247,236
Operating expenses	10,904,040	11,692,731
Earnings from operation	4,994,799	6,554,505
Fixed charges	2,401,652	4,020,503
Net income	2,593,147	2,534,002
Dividends	1,965,243	2,076,233
Surplus	627,904	457,769

The annual report of the Board of Railroad Commissioners of New Hampshire, just received, gives the following interesting information regarding the street railways of the State: Total number of roads reporting, 10; total mileage, 93.7; capital stock, $1,222,000; funded debt, $756,000; earnings, $354,304; expenses, including taxes and interest, $330,092. None of the roads paid dividends.

The annual dinner of the Northwestern Alumni Association of the Massachusetts Institute of Technology, which took place on February 3, in Chicago, was made the occasion for a very interesting long distance telephone "occasion," by means of which the Technology Club in Boston, and the New York, Philadelphia, Washington and St. Louis Alumni Associations were put into connection with the Chicago association, so that verbal messages, brief addresses, speeches and the institute cheer were sent over the wires.

A bill has been introduced in the United States Senate providing for a three-cent fare over all the lines of the Capital Traction Company of Washington, D. C., within the hours of 6 and 9 A. M. and 4 and 7 P. M. The bill will be vigorously opposed.

In a recent communication, the Sprague Electric Company calls attention to the remarkable comparison between the cost of operating the South Side Elevated Railroad in November and December, 1897, when that road was operated by steam locomotives, and the same months for 1898, when the Sprague multiple unit system was employed. These months are stated to be the first months in which a comparison can, strictly speaking, be made be-

tween steam and electric operation. In considering the following figures, it should be remembered that each of the elevated railways of Chicago, which run around the Loop, is charged its pro rata proportion of the running expenses of the Loop, including cost of power, of station service, of repairs and of management, and, in addition, a rental charge of 10 per cent of the gross passenger receipts of the road is made. This latter charge is really applicable to interest on the Loop investment, and is not, properly speaking, an operating expense. The first column of the following table gives the ratio of expenses to earnings of the South Side road; the first includes the Loop rental, and the second column when the Loop rental charge is excluded, while the final column gives the actual net earnings in the months under comparison:

	Per Cent. Operating Expenses to Gross Receipts.		
	Including Loop Rental (a)	Excluding Loop Rental (b)	Net Earnings.
November, 1897, steam	87.3	77.7	$10,604
November, 1898, electric	57.3	47.7	39,449
December, 1897, steam	83.6	73.3	14,692
December, 1898, electric	55.0	45.4	45,356

It is stated that large orders for electrical machinery have recently been received by American manufacturers from Manila and the Philippine Islands.

The first arrest in Boston made for the violation of the new law prohibiting expectorating in street cars occurred recently. The arrest was made on the complaint of a conductor of the Boston Elevated Railway Company, who testified that the prisoner continually violated the law in spite of repeated warnings. The prisoner was fined $5.

Charles L. Bonney, vice-president and general counsel of the Chicago General Railway Company, has issued an open circular to the horse and dummy railway companies of Illinois, in which he pledges the support of his company to forty-five independent companies of Illinois to contest in the courts any law the legislature may enact reducing the fares of street railway companies to four or three cents. The circular calls attention to the Seaman decision in the Milwaukee Railway & Light case, in which the court held that a reduction of fares in Milwaukee would amount to confiscation.

The annual reports of the street railways of the District of Columbia for the year 1898 have been submitted to Congress. The reports in the main are satisfactory and show considerable increase over previous years. The receipts of the Capital Traction Company from passengers during the year ending December 31, 1898, were $932,171; receipts from other sources, $61,006; total receipts, $993,177. The total operating expenses of the system were $537,991, and dividends and fixed charges were $411,107, making the surplus for the year $44,079. This is considered to be a very good showing in view of the fact that a number of the company's lines were in process of conversion to the conduit electric system, and have only just been completed. The Metropolitan Railroad Company reports receipts from passengers as $822,439, and from other sources, $14,379, making a total of $836,819. The operating expenses were $471,358, making earnings from operation $365,461. The taxes were $38,566, interest $143,691, and dividends $74,921. The operating expenses include $46,776, which was expended for the construction of the Connecticut Avenue extension and for other improvements. The surplus for the year is $108,285. The Columbia Railway Company reports gross receipts as $171,397, operating expenses, $76,180; earnings from operation, $95,217; taxes, $7,386; interest, $30,000; dividends, $24,000; for real estate purchase, $2,800, and for construction of the Benning Division, $22,121. The surplus for the year was $8,909.

International News Notes

The Perth police commission, in dealing with the request of the Perth & District Tramway Company for permission to use electric traction and for an extension of time before the undertaking can be purchased under the tramways act, has consented to the use of electric traction, but refused to consider any extension of time.

Both at a meeting of ratepayers and of the District Council of Tipton has it been decided to oppose the bill whereby the South Staffordshire Tramways Company seeks to hand over the rights and working of the undertaking to the British Electric Traction Company. The Town Council of Walsall will also oppose.

At a special meeting of the Sunderland Town Council last month it was unanimously resolved to give notice requiring the tramways company to sell the undertaking, pursuant to the tramways act. Further, it was resolved to proceed with a bill to enable the Council to acquire, work, extend, or lease tramways in the borough or neighboring districts, to supply electric current, and extend existing power station.

St. Helens.—The electric supply and tramways committee of the St. Helens Corporation has been busily pushing forward the work of laying down and equipping the tram lines for electric traction. On the Prescot section the work has been stopped at Cropper's Hill for some time, owing to a request being made by the tramways committee that double lines should be laid in order to insure the safety of the cars on this hill. The committee has now resolved to lay double lines. In answer to the tramway company the committee has stated the order in which it will carry out the proposed extension of the tramways provided for by the local act of 1898. The extension to the Rams' Head, Haydock, will be carried out first, and this will be followed by the extensions to Nutgrove, St. Helens Junction, Derbyshire-hill, to the boundary of Prescot and to Windle City.

Nottingham is solving the difficulty of stopping tramcars by having notice labels "Cars stop here" hung up at stated intervals along the routes.

The Lowestoft Town Council has practically decided to permit the East Anglian Light Railway Company to construct a system of electric tramways in the borough. The proposed line will run from Gorleston to Kessingland. The company will take its current from the corporation, which is about to construct works. Powers are to be reserved that the Council may acquire the undertaking at the end of seven, fourteen, or twenty-one years. The company is also required to make various street widenings.

The question as to whether the Lincoln Town Council should take over the tramways when the company's powers terminate in 1902 was discussed at the February meeting of the Council. It was decided to let the question stand over for a while.

The recent expansion of the Leeds tramway system can be gathered from the following figures: When the corporation took over the business there were 22¼ miles of track, or 14 miles of route. Now there are 42 miles of track, or 23 miles of route. The number of cars has increased from 69 to 127, and 50 more will be added during the next six months.

The tramways committee of the Manchester corporation recently reaffirmed its recommendation in favor of the overhead trolley system as the best suited in every way to meet the requirements of the city and district.

Representatives of the governing bodies of Plymouth, Stonehouse and Devonport are still conferring, and are unable to come to a decision on what lines to purchase and work the tramways in the three towns. The company now working the lines offers to lease and work them if they are purchased. Stonehouse District Council proposes to purchase such portions of the lines as are within its boundary if the corporations of Plymouth and Devonport will undertake to lease the lines on certain terms, which, however, were unacceptable. Devonport will probably proceed to purchase its lines, but Plymouth is doubtful.

The Dundee Town Council has rejected the proposal for a cable tramway in the borough, but has recognized the need for traveling facilities in the district—the North End—by deciding to extend its own system on similar lines to those proposed by the cable company.

The Urban Council of Bexhill has given its consent to the British Electric Traction Company to lay tramways from Kewhurst to St. Leonards.

The Barking District Council has decided to apply to the Board of Trade for a provisional order to construct electrical tramways throughout the town. The estimated cost is £73,284, exclusive of buildings.

A movement is completed for a new electric line from Blackpool to Fleetwood, and should the proposed bridge across the Ribble at Lytham be sanctioned by Parliament, cars will be able to run from Morecambe through Heysham, Pilling, Blackpool, South Shore, St. Anne's and Lytham to Southport. There is already through communication between the four towns in the Fylde, and the new line will run along the coast from Knott End to Pilling, past Cockerham Sands to the Rabbit Hills, where it will bend north, cross the river Lune, and so to Heysham and Morecambe. It is expected to be a popular trip for visitors in the summer months.

Bury, Rochdale, Oldham and several smaller towns are combining to municipalize the train system of that section of Lancashire, and will take over the lines at the expiration of the existing leases in 1901 and 1902, and run the cars with the overhead trolley system.

The electric lines to Phœnix Park are finished and now opened for traffic. The horse cars have been withdrawn, and the section amalgamated with the Dollymount line.

Sir Francis Marindin, one of the Board of Trade inspectors, has announced as a result of his recent inquiry that the speed of the electric trams on the Dalkey & Kingstown section of the Dublin United Tramways Company may be increased to 10 miles an hour on wide roads.

As a result of its recent visit and inspection of the electric train system of Glasgow, the tramways committee of the Aberdeen Town Council has expressed a unanimous opinion in favor of the overhead trolley system. The borough surveyor and electrical engineer have been instructed to report as to the cost and method of carrying out the work of converting existing lines. Cars will be purchased similar to the double-decked cars in use in Glasgow.

Since the beginning of the year the "Birmingham Argus" has been conducting a crusade in favor of an improved train service for the great midland city. Nearly every town councillor has been interviewed, and the result is a wonderful unanimity of opinion in favor of municipalization. The public works committee has just issued a report upon the tramways question, which will be considered at a meeting of the City Council on the 7th of March. The document, which includes numerous tables, embodies a report of a subcommittee appointed to obtain information as to the working of tramways in other towns. This subcommittee addressed a series of questions to thirty of the principal towns of the United Kingdom. In those which have a population of 200,000 and upward, the corporations own and work the lines —Bradford, Glasgow, Leeds, Liverpool, Nottingham and Sheffield. At Edinburgh, Hull, Manchester, Newcastle-on-Tyne and Salford the corporations own the lines, but let them to companies to work. At Glasgow there was a net profit last year of £44,434. Liverpool horse trams, with experimental length of electric trolley, have a capital expenditure of £889,711, and there was a profit last year of £9,553. At Sheffield horse tramways are being converted into electric trolley. The capital expenditure has been £159,377, and last year's net profit was £15,183. There has lately, in the towns referred to, been no material alteration of system. As far as Birmingham is concerned, the question of traction does not immediately arise, and before it becomes necessary for the Council to come to a decision on the subject it is possible that new inventions and improvements will be available. Many corporations have constructed, or are about to construct, tramways on the overhead electric trolley system. In York the construction of underground electric conduit is being considerably extended. That additional tramway facilities are urgently needed in Birmingham can be gathered from the report on the vehicular traffic just presented to the watch committee. In 1896 there were 160 tram cars, 199 omnibuses and 535 cabs in the city; in 1898 there were 162 trams, 235 omnibuses and 700 cabs—an increase of 165 cabs and only two tram cars in the last two years.

In consequence of the purchase of the local tramway undertaking, the Derby Town Council has appointed a permanent tramway committee to take charge of the operation of the lines. It consists of the mayor and eleven members.

The Grimsby Corporation has pased plans for an electric lighting and power station. It will oppose the Grimsby Tram Company's bill in Parliament, as this bill gives the company power to generate its own electric power for traction, and the corporation wants to insist on the company obtaining power from its works.

At a recent meeting of the Edinburgh Town Council the lord provost stated that he had every reason to believe that the whole of the system would be opened by June 1.

J. Clifton Robinson, managing director of the Imperial Tramways, who own the Darlington tram system, has recently had an interview with the representatives of the Darlington Corporation, who desire an improved tram service. Mr. Robinson proposed to equip the Darlington lines on the overhead trolley system, and promised if the corporation would give a free hand and come to terms he would have electric cars running as in Middlesborough by Sept. 1. The matter is under consideration by the Town Council.

J. Shaw, electrical engineer, has been promoted to the managership of the electric tramways of the Isle of Man, in place of John Aldworth, who succeeded Mr. Baker at Nottingham.

A new line 4 miles long, running to Outlane, has just been completed by the Huddersfield Corporation, and has been passed by the Board of Trade inspector. The rails have been bonded, so that when electric traction is introduced the line will not have to be relaid.

The extension of the Halifax Corporation Electric Tramways from Commercial Street to Salterhebble has been completed.

The tramway committee of the Glasgow Corporation recently approved the recommendations of the general manager as to the conversion of the whole of the city tramways to electric traction. The route to follow the Springburn, High Street and Govanhill will be the line from Whitenich to Dalmarnock and London Roads. The route will be by Bridgeton Cross, and will put out of service about 800 horses now used on this line. About fifty-six motor cars will be wanted, and it is proposed to erect a car shed at Partick and Dalmarnock. The next extensions will be from Parkhead to Paisley Road, Maryhill to Mount Florida, Dennistown to Kelvinside, Woodlands Road line, and Possilpark to Govan. The corporation has decided upon a superannuation scheme for the employees in the tramway department. The scheme will be worked in connection with the Tramwaymen's Friendly Society, and the members are to contribute at the rate of 3d. per week for those whose wages are under 18s., and 6d. for those over that amount. For each member the tramways committee will pay 1d. a week, which will amount to £400 per annum. The superannuation will only come in force through temporary or permanent disablement, and the allowance is to be 10s. a week for members of fifteen years' standing, ranging up to 20s. for those who have been members of the society for twenty-five years.

The engineer of the Weston Super-Mare, Clevedon & Portishead Tramways Company has prepared the parliamentary estimates of the cost of constructing the proposed light railway extensions for which this company is seeking permission this session. The total length of these extensions will be about 6 miles, and the new line will run from the termination of the company's existing

road at Clevedon to the siding of the Great Western Railway at Portishead. The cost is put down at £20,250. The extensions will be constructed as single lines.

Sheffield.—The following tenders have been accepted: Cole, Marchant & Morley of Bradford, for two engines for the extensions at Kelham Tower Station, at the total sum of £6,796; John Brown & Co. of Sheffield, for four boilers, at the total sum of £6,250. The British Thomson-Houston Co., Ltd., for two tramway generators of 500 kw. capacity, for the total sum of £5,280 12s. 6d. An extended contract has been signed for the construction and erection of extensions to the power sation at Kelham Island, the city engineer estimating the cost at £10,000. The tramways committee is obtaining tenders for the thirty double-deck cars and the twenty single-deck cars authorized to be purchased. Slipper brakes and trailing wedge blocks are to be provided for all cars.

The prize awarded by the Institution of Electrical Engineers to H. F. Parshall for the best paper presented during the session of 1898, consisted of 25 guineas' worth of books suitably bound and inscribed by the institution.

Mr. Wiseman, C. E., of Birmingham, engineer to the promoters, explained a scheme for an electric light railway between Nuneaton, Chilvers Coton, Attleborough, Stockingford, Ansley, Hartshill and Whittleford to the local authorities of the district, which abounds in coal, clay, stone works and manufactories. A resolution that the scheme had the general approval of the authorities interested was carried.

The British Electric Traction Company is negotiating with the Bath corporation with a view to acquiring the right to lay down electric tramways, and has suggested that the current required might be supplied from the corporation power station. It is not unlikely that this proposal will be carried out.

The Ipswich corporation has decided to open negotiations for the purchase of the tramways in the borough. It will oppose the proposed bill of the company, applying for permission to sell the undertaking to the Drake & Gorham Electric Power & Traction Company, Ltd., which desires to introduce electric traction. The corporation has referred the matter to the parliamentary bill committee to negotiate for the purchase of the undertaking by agreement.

La Société Anonyme de Tramways, d'Eclairage et Entreprises Electriques en Hongrie is the title of a new company organized in Brussels to build electric railways and lighting stations in the western part of Hungary. The company has purchased the large central power station at Steingamanger, which supplies the electric lighting in that city and the power for operating the electric tramways there. It also owns the station at Sarvar, and owns a number of important concessions, including that for the tramways of Oedenburg. M. Lacomble, of Brussels, has been appointed electrical engineer of the company.

At a meeting of the Trambahn Gesellschaft of Metz, Ger., held January 7, it was voted to equip the line with electric power.

The Mannheimer Pferdebahn will be changed to electric power during the next two years, and the system considerably extended.

According to statistics published in the "Electro-Techn. Zeitschr.," the electric railways in Germany in operation on September, 1898, had a total length of track of 1939 km., covering 1429.55 km. of street. At that time there were electric railways in 68 cities. On the same date in 1897 there were electric railways in only 61 cities; in 1896, in 44 cities; in 1895, in 32 cities; in 1894, in 19 cities; in 1893, in 11 cities, and in 1892, in 5 cities. The total number of motor cars Sept. 1, 1898, was 3190, and trail cars 2828.

The Waterford (Eng.) Corporation is about to open negotiations for the construction of an electric tramway system within the town limits.

The electrical equipment of the Calcutta (India) Tramways is being prevented by the City Council, who have expressed an unwillingness to grant the necessary permission requested by the tramway company until the latter carries out certain repair work considered necessary by the council.

Part of the new electric railway system of Ghent, Belgium, has been put in operation, and the remainder of the system will be completed soon.

Three of the principal tramway lines in Naples, Italy, are being equipped with the trolley system. One of these, formerly operated by steam, has a length of 5651 m., a gage of 1.435 m., and a maximum grade of 6.8 per cent; the second has a length of about 3050 m. and a maximum grade of 7.9 per cent; and the third has a length of 5500 m. and a maximum grade of 7.2 per cent. The installation is being carried out by a Belgian company.

At the last meeting of the Dessauer Strassenbahn, Ger., it was voted to equip the line with electric power in place of the present gas motors.

The Metropolitan Tramway Company of Buenos Ayres, Argentina, has been authorized to change its system from animal to electric traction.

The Société Generale des Chemins de Fer Economique, the Empain Bank of Brussels, Belgium, and the Société des Tramways, have purchased for 10,000,000 francs the tramways in Salamanca, Spain, which formerly belonged to an English company.

M. Passedoit, representing Rigaud & Co., has petitioned the Municipal Council of Cahors for right to build an electric railway in that place.

The Whitefield (Eng.) Town Council has created a special committe to consider the erection of an electric lighting station and the construction of a tramway system.

A syndicate of capitalists propose to provide a complete system of electric tramways in Antwerp, Belgium. Arrangements have been made with the existing tramway companies to apply for one general concession for the whole of the lines. The same syndicate is aplying for a concession for a new line from the docks to the Gare du Sud.

The Grösser Berliner Strassenbahn, Berlin, Ger., is planning to equip a number of its important lines with electric power during the coming year.

The firm of Siemens & Halske has closed a contract to build an electrical line between Metschiapu and Pekin, China. It is hoped that the line will be ready for operation during the early part of 1899.

The Saxon Ministry of the Interior has granted the Elektricitätswerke and Strassenbahn Gesellschaft of Zurich, Switzerland, franchises for three new lines.

The Municipal Council of Carcassonne, France, is considering a proposition from the tramway company of that city to equip the lines with electricity.

It is reported that the Brussels Cômpagnie Mutuelle des Tramways will secure control of all the tramway companies of Antwerp and will introduce electric traction on the 42 km. of tramway track in that city.

The municipal council of Bordeaux, France, has granted the petition of the Tramway and Omnibus Company of that city to equip the tramway lines with electricity.

The Oberschlesischer Strassenbahn Gesellschaft, of Upper Silesia, Ger., which is equipped with electric power, is proposing to make a number of extensions.

M. Robi, manager of the Société des Tramways de Tiflis, Caucasia, has recently obtained permission from the authorities for the equipment of the line with electricity.

The Westinghouse Electric & Manufacturing Company has been awarded a contract for the electrical equipment of fourteen cars for use in the city of Cairo, Egypt.

Storage Batteries and Railway Power Stations *

BY ROBERT MC A. LLOYD.

The difficulty confronting us is that very few operators of railway power stations have any data showing what they are doing. Electric light managers seem to take more interest in the output of their stations, and in many cases maintain a system of records of work done, but the manager of a trolley road is usually contented with superficial observations of the switchboard and the comforting fact that the cars are running.

We always find these managers greatly surprised when the actual state of affairs is shown to them on paper, and I believe that this institute would be astonished at the results of a thorough research into the load curves of the railway plants of the entire country. You are, of course, prepared for the statement that the average load on a railway power station for a given period is much less than the maximum load occurring during that period and much more than the minimum, but it is not generally understood that the maximum load for the same period is apt to be far below the capacity of the generating plant in operation. As an illustration of this fact I show some data on a typical railway plant when thirty-five cars were running. We have not discovered any railway plant where this is not true and I believe that the data on most of the railway plants of this country will confirm my statement. The first explanation of this would be that such a surplus capacity is necessary for reserve to meet emergencies, but I do not find it to be a useful reserve, and shall refer particularly to the diagram, taking this station because, from the standpoint of the manager, engineers and attendants, it is dangerously overloaded and has no reserve. In fact it was necessary to add to the capacity at once to make it safely operative. (See diagram on next page.)

I obtained these data on the day of heaviest travel in the whole year. It will be noticed that the highest point reached was within the capacity of the main station, and yet it was necessary to start up an auxiliary station. The central solid line shows the average load, and the upper and lower lines show the limits of the fluctuations occurring from moment to moment. The method pursued in getting these curves was to divide the day into half hours, and during the first five minutes of each half hour take the highest and lowest ammeter reading in each minute; these readings are plotted in the upper and lower curves; also to take ammeter readings every five seconds and obtain the average of these readings as the point in the curve of averages. Another convenient method of obtaining the curve of averages is by wattmeter readings. Among some of the interesting features in this diagram may be noticed the fact that the nominal capacity of the generating apparatus was about 400 kw. in excess of its maximum output occurring at about 8 o'clock in the evening, and that the average output at this time was about two-thirds of the maximum. The excess of nominal capacity was not so great at 7 o'clock in the morning, or 2 in the afternoon when other high points occurred, but as it was known that the morning peak would be of short duration the engineer decided to run through it without the auxiliary station, and in the afternoon the load increased more rapidly than was expected, and the auxiliary was not ready to go into operation on short notice, consequently obliging the main station to groan under a dangerous load for an hour or so.

It will doubtless occur to some that this station apparatus has been overrated, or that the engineer was incapable or over cautious, but the fact remains that similar data are obtained in very many stations, and that in many cases the apparatus has been subjected to satisfactory tests before acceptance by the purchasers. It may be possible to build engines which regulate at all conditions of load and at the same time use steam satisfactorily at maximum load, but I do not find such engines commonly in use. Further than this there are many very good engines in use which cannot be safely operated at anything like maximum load if that load is liable to sudden variations. I realize that you may suggest all sorts of schemes for getting a better output from the plant illustrated by this curve, and you may wish to ask some questions about this apparatus, but experience convinces me that the men who are most likely to be consulted about such a station will recommend more generating plant, and the truth is that there are so many good salesmen pushing engines and dynamos that station managers frequently fail to get full duty from the machinery which they are operating already. It is not merely that the storage battery has been neglected, but any of us can see in railway power houses throughout the country, where the managers have been persuaded to increase their generating plant when attention to a few details such as steam piping would have brought their output up to requirements. Assuming, however, a station equipped with the best obtainable apparatus, and operated under the most advanced laws of station practice, in the absence of a storage battery, there would still be much more apparatus running than would appear necessary from the load diagrams.

The generator salesman says in reply to this proposition that his apparatus is cheap and that it is good to have plenty of it, but one generally finds that where there is plenty of apparatus available the engineer is tempted to keep too much of it running, and therefore running at low efficiency.

Of course railway power stations have individual characteristics, and it will not do to assume that they all need storage batteries, but there are certain features of railway power requirement which are common to the problem everywhere, and which invite consideration for the storage battery.

The curve characteristics of electric light supply are well known, and much information about electric lighting has been brought out in the committee reports of the National Electric Light Association for 1896 and 1897 and by Mr. Hammond in his paper before the British Institution of Electrical Engineers in March, 1898, but the possibilities are more varied in railway work, and, as far as I know, there has yet been no systematic research into the economy of railway power stations, the only published data on the subject being contained in the paper read before the Street Railway Convention at Boston last September by R. W. Conant.*

In my endeavor to point out some of the uses for a storage battery I shall take as a typical station that shown in the diagram. It is located in a Pennsylvania town of 50,000 inhabitants. The railways radiate from the center of the town to distances of 3 to 9 miles. There are six branches and the power station is located 2 miles out on the longest branch. It has railroad and water frontage. The small auxiliary power house is the result of a recent consolidation and is close to the main house. There are three distinct ways of using a storage battery with this power plant. Taking up the figure we find first the great fluctuation between night and day load; second by the fluctuations occurring from hour to hour; and lastly the superimposed fluctuations occurring from moment to moment. We shall call a battery of sufficient capacity to level off the night and day fluctuations "large;" a battery for leveling the hour-to-hour fluctuations "medium," and a battery to level the momentary fluctuations "small." It will be seen at a glance that the small battery will reduce the requirements of the generating plant to a capacity sufficient to meet the demands of the average load shown in curve A. The battery must be able to discharge at 650 amps. for momentary periods, but its capacity in amp. hours is unimportant. It will cost less in generating capacity for the same work, and a large part of the excess of capacity over requirements shown in the diagram will be saved. It will save some depreciation on the generating apparatus, and its own depreciation will not cost more than the depreciation of generating apparatus of similar capacity. It will have sufficient storage capacity to run a few night cars and lights when the engines are shut down. If located at a point nearer the center of feeder distribution than the location of the generating station, a saving in copper will be effected. Inasmuch as the investment will not be increased by including such a battery in this railway outfit all the saving in fuel due to a steadier load and the operation of less generating machinery will be clear gain to the credit of the battery.

Line B, at 810 amps., shows the average load for 18 hours of the day, and a "medium" battery to reduce the load to this straight line would have a capacity of 1300 amp. hours. It will cost about twice as much as a "small" battery, but will not add enough to the cost of the installation to bring the investment up to the total now in generating apparatus alone and presumably necessary if no battery is used. This battery will have all the advantages of the small plant with wider limits of operation. The station circuit breakers may be set 650 amps. higher, and there will be greater convenience throughout the station in operating at a fixed load. There will be a marked effect on the efficiency of all departments of the station, and all the apparatus will yield a higher output in proportion to investment and cost of operation.

Line C, at 650 amps., shows the average load for 24 hours and a "large" battery capable of leveling off this load will have a capacity of 3000 amp. hours. It will cost approximately twice as much as the "medium" battery and will have all of its advantages. It will cost as much as the generating machinery displaced by it. It will add largely to the flexibility of the station. This battery could be discharged momentarily at 3000 amps., which will put the circuit breaker limit of the station at about 3600 amps. instead of 2300 with all the present apparatus. It may be discharged at 1500 amps. for one hour, which will be sufficient to cover load peaks that would stall the 1150 kw. generating plant completely.

In cases of extreme necessity the entire system might be carried

* Paper read before the American Institute of Electrical Engineers, Feb. 15, 1899.

* See STREET RAILWAY JOURNAL for October, 1898.

by this battery for several hours. The ability to carry sharp peaks is a distinct addition to the earning power of the system. Such peaks often signify the collection of fares which would be lost if the system were not flexible, and some managers keep up enough station capacity to carry a few holiday crowds while for 99 per cent of the whole year it is earning nothing. Other managers do not attempt to carry special crowds. The large battery will give the manager an opportunity to get all the money that can be made out of such business without feeling that he has made any investment for the purpose. Of course the capacity of the system is limited also by the investment in copper, but in many cases the battery may be located so as to facilitate the distribution of power.

There is no reason why a railway power station of this capacity running night and day at a constant load should not attain a fuel economy as high as that of the well-known Chestnut Hill pumping station at Boston, which would be equivalent in electrical work to 557 watt hours per pound of coal. Curve A shows for one day's work 7,800,000 watt hours which required at the above rate 7 tons of coal, and assuming that the battery would only have 75 per cent efficiency, and that 25 per cent of the entire day's work would go through the battery, ½ ton of coal would be added to this consumption, making 7½ tons of coal per day for this plant, running with a large battery.

The battery efficiency in such service as this has been found in most cases much higher than 75 per cent, and in some cases over 90 per cent, so my estimate is clearly on the safe side.

Table I.—Comparison of First Cost.

	Lay Out With	Cost of Generating Apparatus.	Cost of Storage Battery.	Total Cost of Station Plant.	Cost of Coal per Day.	Cost of Coal per Annum.	Saving in Coal.	Saving in Coal and Saving in Int. 5 p. c.
		$	$	$	$	$	$	$
1	No battery	115,000	------	115,000	30	10,950	----	----

save anything in the cost of operating the road, but that they could not run without it, and I take the liberty of making the following

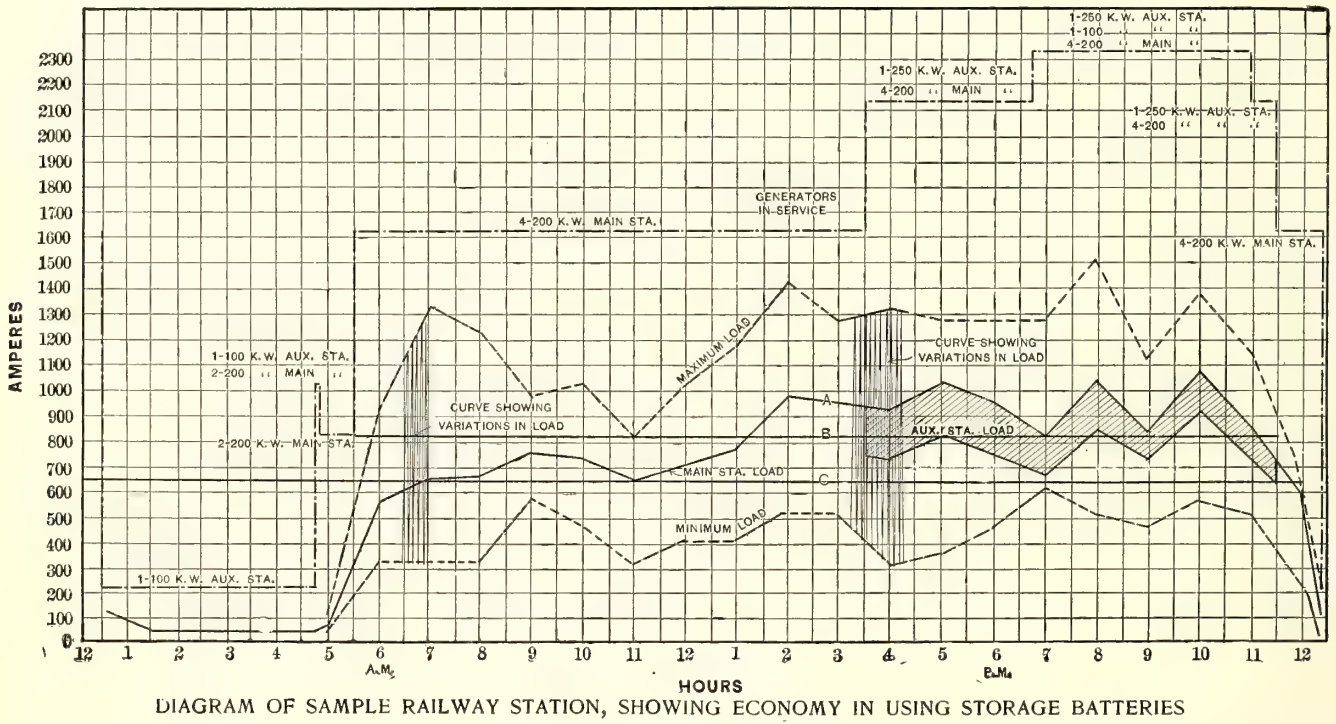

DIAGRAM OF SAMPLE RAILWAY STATION, SHOWING ECONOMY IN USING STORAGE BATTERIES

On the day when these data were obtained 15 tons of coal were burned, or twice as much as would be necessary with the battery outfit. The battery would, therefore, save at $2 a ton, $5,474 per annum in coal alone.

The number of men in the station is now the same night and day, and there would certainly be no increase in the labor item, whereas it is probable that one man on each shift might be dispensed with if the plant were reduced by the battery, in which case there would be another saving of $1,200 per annum. The battery would also save water, oil, waste, etc., and there would be minor advantages such as more constant potential on the line; less annoyance from circuit breakers; no fear of sudden demands on the generating apparatus and the disagreeable possibilities incident thereto.

In the following table some figures are tabulated for the purpose of comparing four different layouts to meet the requirements of the railway system referred to in the diagram:

I have assumed $100 per kw. as the cost of complete station apparatus without batteries. This figure might have seemed high a year ago, but in view of the rising prices of such material I think it is only conservative.

In regard to the "small" battery, there is no doubt of its advantages in many cases, but for new installations it is not always the most economical battery. I understand that Leslie Carter, the president of the South Side Elevated Railroad Company in Chicago, said recently, that, as far as he knew, their battery did not extract from his annual report to the stockholders, which has since been published:

While the amount of current used per car-mile is low, and has produced gratifying results in all tests and comparisons made, the fluctuations of power above the average requirements are large, and the sudden demands on the power-house compelled us to prepare promptly for the heavier business of the winter, which, with increased number of cars in service, heat, and light loads, would have been beyond the capacity of the power-house. Additional Twelfth and Sixty-first Streets, respectively. These batteries have greatly re-engine capacity could not be obtained in the time at our disposal, would have cost more money, and have been expensive to operate. We accordingly installed two batteries of 750-kw. each, equidistant from the power-house, at duced the fluctuations and the maximum load at the power-house. While the output at the power-house is the same, the batteries charge at times of light traffic and discharge at times of heavy traffic, thus equalizing the work at the power-house, and relieving the engines and generators. This is certainly an economy, and it is further claimed, with what correctness I am not yet convinced, that they cheapen the cost of production. But I do know that they keep up the voltage at the ends of the line, enable your road to operate more cars, furnish increased facilities to patrons, and prevent damage to power-house machinery in case of sudden demand for increased power.

That battery was, of course, put in for regulating purposes only, and the load curves give an impression that the battery must certainly be useful. It seems to me hardly worth while in laying out a new station to put in a battery for the purpose of reducing the railway power curve to the characteristics of electric light practice, when by going a few steps further it may be refined to a practice comparable with marine engineering.

It might appear at first thought that a battery of sufficient capacity to insure a full load for the generating units at all times, would save as much fuel as a battery large enough to level off the 24-

hour service, but it is very difficult to follow the power requirements from hour to hour in such a way as to make ideal use of a battery, whereas with a "large" battery it would be possible for the ordinary station engineer to adjust his load so as to operate all of his apparatus to the best advantage all the time.

I have carefully analysed the figures in Mr. Conant's very interesting paper above referred to, and am compelled to differ from him at some points, and refer to them in order to meet in advance any criticism of my paper which may be based on his tables. In the first place he assumes that his standard station can be worked all the year round with a load factor of 33 1/3 per cent, which is entirely too high; 20 per cent or 25 per cent would be more normal. I suspect that Mr. Conant's load factors have been obtained by indicator cards instead of wattmeters. In Mr. Conant's table none of the stations shows a better figure for coal than 3 lbs. per kw. hour, while his standard station is put down for 2.2 lbs., without any intimation of the process for attaining such a good result. The question as to how the cost for repairs and depreciation of the entire plant would be affected by a large battery is particularly debatable ground. Mr. Conant allows 2 per cent for depreciation beyond the normal running repairs. He estimates the entire plant, including buildings, to last 50 years. His statement that the machinery now being installed will last much longer than that with which we have been familiar in the last decade has nothing to back it up except faith in the promises of the builders.

I propose to allow 10 per cent per annum for repairs and depreciation, on the entire station apparatus, including batteries. I have not seen any boilers that are likely to last 50 years, and there is plenty of evidence that all the best engines and boilers in this class of service to-day will go to pieces in a life of from 10 to 20 years. The particularly hard usage to which most of them are subject is not only steadily wearing them out, but producing a state of constant danger and not infrequent accidents. I am sure this is becoming well understood among railway men, and some of the best managers are writing off to depreciation 10 per cent per annum. Moreover, who can say that improvements will not be made in the next 10 years as in the past, and that engines and boilers may be out of date before they are used up.

It is, of course, well known that whatever the rate of depreciation may be without batteries, it will be lowered by giving the generating apparatus a constant load; my belief is, therefore, that the storage battery will not increase the rate of depreciation for the entire plant. If it can be shown that interest and depreciation for a plant of given load dimensions are practically equal with or without a large battery, it is evident that the great saving in fuel alone will determine the superiority of the battery system.

I have so far considered the battery only at the central generating station so that all the advantages due to locating it at proper points in the distribution system are additional arguments in its favor. In many cases the saving in copper may be greater than the sum invested in the battery, and the flexibility of the system improved in places where it would not pay to install sufficient copper to meet the irregular demands of travel.

The reserve qualities of the storage battery are unique. It might be supposed that a mere reservoir which is quickly drained would be of little value compared to a lot of extra generating apparatus standing idle, but experience is demonstrating every day in existing plants that the reserve which is needed most is the reserve which is not only ready for emergencies, but actually alive to any demand without the direction of a human mind.

Most of what has been said of the storage battery as applied to the power station illustrated by the curves is true of its application to railway power stations in general. The use of water power introduces a factor in the problem more variable than fuel, and I shall not attempt the discussion of it. Alternating currents lend themselves readily to the development of storage battery applications on account of the mutually helpful combination of battery and rotary at sub-stations. Up to the present time, each of the large batteries installed for railway work has been obliged to meet different conditions and requirements, but they are all serving their respective purposes well and showing many different fields of usefulness. I shall not refer to these plants, because Mr. Appleton in a recent lecture to the New York Electrical Society has ably described those of most importance.*

Most of us feel that the electric railway and electric lighting interests are destined to get into closer relations, and the generating station of the future may be required to furnish all the electricity used within large areas for every purpose.

Coming finally to a problem which has been the subject of some newspaper discussion of late, I trust you will pardon me for treating of work with which I have no connection. Electricity has so many advantages over any other medium for transmission and storage of energy that I assume its use to be firmly established and cannot conceive of any lasting rivalry by the other contestants now in the same fields. Further than this, without saying anything for or against monopolies, I believe that all the energy supplied by means of electric currents to consumers of every nature in the greater New York should radiate from two or three central stations, and that these should be electrically tied together. The sub-stations would naturally consist of rotaries and storage batteries. It may not be possible to lay out each sub-station so that the rotaries would run at a constant load for 24 hours a day, but it seems to me quite probable that such an arrangement would eventually be reached, and this would, of course, give the generating stations a constant load.

At the present time the load curves of the electric railways are very uncertain, and peaks are likely to occur at almost any time of day, while the addition of the peak due to electric lighting in the early evening would not add in large proportions to the railway peak, but electric lighting is capable of more general application and it is possible that within a few years the distribution in the Borough of Manhattan may reach from 300,000 to 500,000 kw. at the highest part of the lighting curve, which will probably be as great as the railway load when the elevated railway and the underground rapid transit are included. These peaks will often occur at the same time of day, and so there is no possibility of improving the load factor of either system by splicing the two together. It follows, therefore, that what is true of the relation of a storage battery to the economy of the generating station for power or light separately will be true of the resultant of their combination.

The railway and light people recognize the importance of leveling up some portions of their load curves, but I estimate that the greatest saving is to be obtained by operating for a constant load twenty-four hours per day. However high would be the economy of such large stations I am sure it would be higher with large batteries than without. Certainly the economy of the Boston pumping station as to fuel consumption should be surpassed. It must not be assumed that a high load factor for the system is an advantage. It is all right for the generating plant and for the copper feeders, but the kw. hours that bring in the most money may spoil the looks of the load diagrams and kill the load factor. What is required to earn dividends is a *profitable* load factor outside of the stations, whether high or low, and the highest possible load factor at the dynamo terminals. The large storage battery meets these two requirements perfectly. A load factor of 100 per cent may be maintained at the dynamo, and current may be sold to the consummer regardless of the time of day.

With 1,000,000 kw. in view for the Borough of Manhattan it would be necessary to generate an approximately constant force of 300,000 kw. A million kw. in station plant without the battery factor would cost $100,000,000. The same capacity, including the proportion of battery now deemed advantageous by some of the engineers in touch with these problems, would be divided as to cost into $70,000,000 of generating plant and $30,000,000 of battery plant. Finally the same capacity, if divided in the same proportions which seem to me most productive for the investment, would cost $30,000,000 in generating plant and $70,000,000 in battery. This is quite a large battery plant, and as there would be more than two parts battery to one part generator, I am fearful of the jealousy which such a reversal of engineering practice would create.

In conclusion I wish to state that nothing in this paper should be regarded as emanating officially or unofficially from the company with which I am connected.

* See STREET RAILWAY JOURNAL, February, 1899.

Completion of St. Anthony Falls Transmission Plan

The equipment of the power house at the lower dam of the Falls of St. Anthony at Minneapolis, Minn., is about to be completed, and the necessary arrangements have been made by the St. Anthony Falls Power Company with the General Electric Company, which manufactured and installed the plant now in operation.

The hydraulic work and the power house, which were described in the STREET RAILWAY JOURNAL for May, 1898, were finished in the spring of 1898, and five three-phase alternators of 700 kw. each and two direct-current generators of the same capacity, with the necessary rotary converters and static transformers, were installed. The full equipment of this power plant, as originally laid down, contemplated the use of eight alternators and two direct-current machines of the total capacity of 10,000 h.p.

The additional equipment will consist of three 700-kw. three-phase revolving armature alternators, with rotary converter, step-up and step-down air blast transformers, and switchboards for the generators and converter. The installation of this machinery will raise the generating capacity to the 10,000 h.p. originally contemplated.

Some General Observations on Electric Traction*

BY H. F. PARSHALL

It is a natural thing for engineers to reason from experience with electric lighting plants as to how best to design plants for electric traction purposes. Such reasoning, however, is likely to be defective and lead to wrong results. A primary difference between electric lighting and electric traction, so far as the station is concerned, relates to the difference in the nature of the load—one being approximately constant from moment to moment, and the other varying between wide limits, and at such a rate that many engineers liken the strains upon traction apparatus to those upon rolling-mill engines. Another difference of great importance is, that in a plant of a given nominal horse power from three to five times the quantity of electricity would be generated for traction as for lighting purposes; consequently a greater capital investment, greater refinement in the machinery, and greater margins in the individual machines, or in the number of spare machines, are commercially permissible in the case of electric traction. In general, lighting machinery is called upon to work at full load for a few hours in the day, whereas traction machinery is generally called upon to work at approximately full load for many hours in the day.

The steam generating plant for either lighting or traction of the same capacity need not differ in character to be equally efficient. Having reference, however, to the better load factor of the traction plant, and consequently a greater consumption of coal and a lesser ratio of cost of labor to that of material, better arrangements as to coal handling machinery and coal storage are justified. More elaborate arrangements of steam piping are also justified, since the loss due to condensation in steam pipes is determined by the number of hours the pipes are under pressure, rather than by the quantity of steam carried by them.

Steam engines have been the subject of frequent discussions. It has been a much debated point as to whether or not an engine should have a heavy fly-wheel. This question resolves itself into the most economical way, average loads considered, of getting the maximum effort from the steam engine to take care of the temporary overloading incident to traction work. The dimensions of the cylinders of engines for good economy are determined with reference to average loads. For best economy then at good regulation, heavy fly-wheels are necessary to assist during overloads in traction work. The question of governing has also been frequently discussed. I do not understand why this should be, since nobody is of the opinion that an engine that governs closely is at a disadvantage. Such engines do not cost appreciably more, and are now generally manufactured. In reading such discussions I have frequently wondered why the electrical conditions met in parallel running have not been taken into consideration. The necessity of close regulation of steam engines was first demonstrated in the case of generators running in parallel, where the load did not properly divide with rapidly varying loads unless the engines governed with fair accuracy.

Another matter frequently discussed is that in respect to the speed of engines. Here, also, the electrician is entitled to some voice, since experience has clearly demonstrated that each size of dynamo has a range of speed through which its performance either as to efficiency, regulation, or sparking, is best, and dynamos built outside of this range of speed are made at the expense of efficiency, regulation, or commutation.

The speed of the 1500-kw. dynamos which I designed some years ago was limited to 75 r.p.m.. Experience since then has not demonstrated the advisability of increasing the speed beyond this figure for this size of machine. My own experience justifies the statement that the mechanical and electrical conditions, in the case of the larger direct connected generators, generally coincide in the matter of speed.

The system of transmitting mains for distribution, on account of the better load factor in traction installations should be designed, for most economical working, with a greater cross section than in the case of lighting, with its smaller load factor. This is obvious from Lord Kelvin's law, in which the interest that goes on perpetually is balanced against the cost of the energy wasted in the mains. Clearly, then, as the cost of energy does not vary in the simple ratio of load factor, if mains *are* to be utilized three or four times as many hours in the year at rated capacity in one case as in another, a large cross section cable is required, if the cost of wasted energy is to balance the interest account.

Apart from the proper designing of a given system of transmission and distribution, there remains the broad question as to what will be the nature of the transmission, that is, whether continuous currents shall be used, or whether the distribution shall be multiphase with substations. The solution is to be determined in respect to the amount of power and the distance to which it is to be transmitted, and in particular cases to the conditions of distribution. Thus, where a very small voltage drop is permissible in the consumer's circuits, as in the case of earth returns, multiphase transmission, with frequent substations, becomes a necessity, where under less restricted conditions continuous current transmission would be more economical.

For comparison between continuous current high tension transmission and multiphase transmission, see Proceedings Institution Civil Engineers, Vol. CXXXIII, Paper No. 3090. It appears from this that the distance at which multiphase currents become efficient as compared with continuous currents is somewhat less at 500 volts than has been frequently thought.

The fixed losses in a multiphase system for the distribution of power for traction work are determined largely by the maximum momentary load which may come upon the substations. When the ratio of the average to the maximum temporary load is comparatively large, the distance at which continuous currents become more efficient than multiphase currents is increased. In very large traction installations in which the ratio of the average to the maximum approaches unity for average working, the distance beyond which high tension currents are more advantageous is lessened. What method of transmission will be most efficient in a particular case cannot be determined without knowledge as to the nature of the load. In the Dublin installation which I have recently designed for 250 cars, the power station is approximately in the center of the system. The average distance of transmission is about 2½ miles. I have used 500 volts continuous current with so-called "boosting machines," taking the current out of the rails at certain points, so as to restrict the maximum drop in the earth to 2 or 3 volts. For two lines extending some 8 miles from the power station I have, at a distance of about 6 miles, planned to install a rotatry converter station. The multiphase load, however, being such a small fraction of the whole, I have not installed multiphase generating machines in the station, but have used a special design of rotary converter, run from the main machines. Such rotaries have to be very specially designed, since, in the case of the current becoming displaced in phase, they are apt to race dangerously. This is a particular case, designed after determining the average current consumption in any part of the system, when the ratio between the average and the maximum is approximately known from experience, so as to impose the minimum fixed losses, or, in other words, to insure under average conditions maximum efficiency. Were the number of cars doubled I would locate substations approximately at the feeding in points and would use multiphase transmission.

An advantage in the use of rotary converter stations is that at constant speeds such machines will give constant voltage, regardless of the load or the drop in the lines (provided this be limited to an economical amount), or the regulation in the transformers, so that such machines can be made to supply simultaneously and satisfactorily both traction and lighting installations. To justify this statement I instance tests recently made on some 900-kw. rotary converters, from which full load could be thrown on or off from one to the other machine without any perceptible variation of the continuous current voltage.

In the designing of a multiphase system selection has to be made between quarter and three-phase. The three-phase system has the important advantage that but three-quarters of the weight of copper is required as with either single or quarter-phase transmission. Considered, therefore, with the energy factor common in multiphase working, the three-phase system gives better transmission efficiency with the same section of copper in the average case as continuous current.

Another advantage is gained when the transformers are delta connected. Any one of the three can fail, and the other two will deliver triphase currents to the rotaries. There is practically no difference as to efficiency or working between the rotary converters in the two cases. In installations making general use of rotary converters feeding into a network at constant voltage it is necessary to observe some care in selecting the high tension mains, and in securing engines with approximately constant angular velocity. An engine, to be entirely satisfactory, should not produce by variable velocity a phase displacement of more than 5 degrees per half cycle from that of constant velocity. The transmitting mains should be designed with comparatively small drop, so that the rotary converters work properly in parallel in different stations, and so that the rotary converters can generate constant voltage with a varying load without too great phase displacement. If proper precautions are not taken in these matters rotary converters will not operate satisfactorily in parallel, and are likely to give a great amount of trouble from sparking and irregular variation of voltage.

* Paper read before the Northern Society of Engineers Jan. 24, 1899.

For working with rotaries I would also point out the necessity of arranging the mains so that the current in each phase is delivered approximately at the same voltage. I have recently been conducting some tests on rotaries, working on triple concentric mains, and the results were far from satisfactory until a phase equalizing arrangement was used. At first the current in the different phases varied by about 10 per cent, and the rotaries worked unsatisfactorily; when, however, the e.m.fs. were equalized the rotaries worked with entire satisfaction. The conclusion to be drawn from this for three-phase working is that the cables should have equal inductance, equal capacity and equal resistance in each circuit.

In installations which I have designed I have used cables drawn in conduits and with manholes approximately 150 yards apart, so that the cables can be readily replaced or supplemented to meet the demands of the service. Armored cables laid in a common trench are objectionable, in that the burning out of one is quite likely to destroy its neighbor.

By far the most difficult problem to solve at the present moment in large multiphase stations is in conection with the switching apparatus. Circuit breakers have been devised for continuous currents that will open at any current to be met with in practice. In the case of alternating currents the same progress has not been made. I recently examined the plans of a 70,000-h.p. station, and could not but feel that the success of the whole installation was dependent upon the switching arrangements.

In this discussion I have assumed that the distribution in a traction system would be by continuous currents. I have seen nothing that would lead me to believe that any other course will come into general use.

The next point for consideration is as to what form of apparatus should be used for conducting the electricity from the distributing mains to the car; whether it should be the single-wire, overhead trolley system with earth return, the two-wire system with return overhead, or with this last connected up as a three-wire system, with the middle pair of trolley wires acting as a neutral, or whether a conduit system should be used. The valid objection to the single overhead trolley system, neglecting the æsthetic one, is in the use of the earth as a return circuit. Troubles from electrolysis have been frequent in the United States where the e.m.f. drop in the earth return is not limited by legislation. Owing to the stringent regulations of the Board of Trade little trouble has yet been experienced in England or on the continent, where similar regulations are in force. I pointed out in a paper which I read before the Institution of Electrical Engineers,* that with even very little e.m.fs. a certain percentage of the current in all cases leaves the rails. With amounts of copper commercially permissible, either substations at frequent intervals, or boosting machines, such as have already been described by Major Cardew and myself at the Institution of Electrical Engineers, are necessary to bring the e.m.f. drop down to two or three volts, which in most cases of municipal working is the safe limit. If the e.m.f. exceeds this limit trouble from electrolysis would probably occur at some date more or less remote, according to the local conditions as to the location of the earth return in respect to the gas and water pipes and the nature of the soil.

The double overhead trolley system eliminates the possibility of trouble from electrolysis. In the case, however, of most cities where numerous lines converge at certain points, the double overhead construction would be complicated and objectionable in appearance. The same applies to the double overhead three-wire system. This last system has great advantages, however, and when used in connection with rotary converters, which act both as converters and equalizers, it is possible to operate tramways over very long distances from the generating stations. It happens in such cases that the three-wire overhead system is rarely objectionable, since overhead networks are not necessary to meet the traction conditions in outlying districts.

The conduit system has been used in various American and continental cities with a considerable degree of success. The advantage is that it can be a doubly-insulated system, avoiding danger from electrolysis, and that there are no overhead wires. An additional rail at the side, or pair of rails between the tracks, along the slot, has to be set off against the overhead wires on making comparison between the two systems as to appearance in the street.

In general, city corporations are in a better position to install conduit systems than private companies, since the city corporations can borrow money at low rates of interest and have not so great amortization to consider. Further, city corporations frequently having the control of gas and water pipes, can arrange matters so that the conduits can be put in at a less first cost. In some cities I believe the installation of conduits under a dual management would be impracticable, since the conduits would interfere with the gas and water pipes to such an extent that the conduits could not be installed except by such general rearrangement that local arrangements could not be made. Undoubtedly, in the case of heavy storms the conduit system is more troublesome than the overhead system. I had some examples of this in my recent visit to the United States. In New York it has been found necessary to employ an elaborate system of double-throw switches, so that if a part of the positive side of the system goes to earth it can be put on the negative side, and the negative on the positive side.

In conclusion, I would point out that the mistake most frequently made has been in underestimating the amount of power that may ultimately be required in a traction system. Both the size and type of machinery in a generating station should be determined in respect to the maximum output of the station. Having regard to the present regulations of the Board of Trade and to economy in transmission and distribution, the limit for a 500-volt continuous current station is usually reached at 5000 kw. output. Beyond this a multiphase system of transmission, with rotary transformers for continuous current distribution, becomes necessary for most economical working, since experience has fully demonstrated the greater economy of working from a single central power station. The "universal" station is the multiphase station, since it can meet every condition with a single type of generating machinery. As pointed out in the paper, however, the distance of transmission, amount of power, and the nature of the load are the factors determining whether a continuous current or a multiphase system is best in particular cases.

Having regard to lighting experience in the large American cities in which the three-wire system was originally installed, and which is now being replaced by a three-phase system with substations to secure greater economy in working, it would seem wiser in many cases to sacrifice somewhat in electrical efficiency at the beginning, and provide for a plant suitable for practically unlimited growth, either as to amount of power or area of district supplied from a central power station.

* STREET RAILWAY JOURNAL, June, 1898.

The Electrical Inspection of Street Car Equipments*

BY ALBERT B. HERRICK

As electrical machinery is becoming such an important factor in modern civilization, the maintaining of this machinery requires indirect methods in order to make visible, through the means of instruments, the electrical conditions of the apparatus or machinery. Nowhere in the application of electricity is electrical inspection more necessary than in street railway equipments; here the motor is operated with exposure to weather, mechanical jars, heating and severe electrical and mechanical strains, and when the first roads were operated there were many predictions that this system was impractical, and a preposterous engineering proposition. The development of accurate methods for finding these hidden electrical troubles in an equipment has been urged upon me by reason of the high cost of the electrical repairs on street-car equipments. These aggregate many million dollars per annum in the United States, and to bring this forcibly to your minds, in two of the roads which I have examined I have found the cost of the electrical repairs of a 22-ft. car with double equipment to be the same as an 80-ton locomotive running on the Pennsylvania Railroad the same distance and carrying a full train of freight cars.

The wiring of a car, by which the current is conducted through the equipment, is of necessity not a fixed nor rigid system. The resistances which are used to control the flow of current through the equipment, on account of their limited weight and space, will not carry the current continuously, and careless motormen may injure the resistance by improper handling of the controller. The latter, which is practically the nerve center of the equipment, reflects in its depreciation all the latent defects in the equipment. After carefully inspecting, electrically, a large number of equipments, one feels very much like diagnosing the different diseases which are inherent in the various equipments, and also separating from these diseases those which are developed by forcing or the improper handling of the controller, and which are attributable to poor motormen. There is another class of diseases which have their origin in careless inspection and careless maintenance of the equipment.

It is not so much my intention to analyze the diseases to-night as to describe the means by which they are detected and located.

Following out our original anatomical idea, it is easiest to look at the various ramifications of the current flowing through the

* Paper read before the Franklin Institute, Philadelphia, Feb. 14, 1899.

equipment as a circulating system, with the controller as a deflector for these different circuits through the equipment. Fig. 1 shows a very common form of series parallel controller, with the connections it makes with the apparatus on the first notch; with each movement of the controller handle the current is changed in its path. The sequence of changes made by the controller as it passes from the first position to the last, including nine positions in this case, is as follows: The first position starts the current flowing through the electrical circuits of the car, and the car should now move. A large amount of energy is lost now in the resistances R_1, R_2, R_3, R_4, which choke down the initial current on the motors. An advance from the first step to the second cuts out 4½ ohms in a standard equipment of this type; from the second to the third step cuts out 1½ ohms, and from the third to the fourth step cuts out one-half an ohm. The motors are now both in series and across the full potential between the trolley wire and the ground. The rheostat, which is the resistance that has just been cut out by the first three steps of the controller, is usually given very little attention after it has been installed on the car. Its resistance generally increases with age, however, and I have found in many rheostats over four times the resistance they should have had when new. The result of this increase in resistance is that the car will not start on the first step of the controller when the rheostat is hot or the car heavily loaded, for the resistance is so high on this step that the current is cut down below starting value, and when the second step on the controller is reached the car will have what is known as the "kangaroo" start. The result of this defect in the equipment is to increase the temperature of the motors and the strains on them, as well as the current demand on the station, and to give a disagreeable acceleration to the car. This defect is more noticeable on those motors having a large starting torque. The motors which have a small starting torque do not show this defect so much in the start and car acceleration, but struggle along under this excessive condition until they retire to the repair shop damaged.

I have expanded on this point somewhat, because it does not seem to be generally known that this condition is primarily the cause of a large number of breakdowns in equipments, which condition may be caused by burnt-open or high resistance in rheostats. A low resistance on the first step of the rheostat has identically the same effect on the equipment as if the first step is too high and the second step is normal. Where repair accounts have been kept against individual cars in street railway operation I have often found the high cost of repairs on some cars due to just this rheostat trouble, the controller, armature and fields being continually repaired, while the rheostat, which is the real cause of the trouble, is left unmolested.

Rheostats are also much more heavily strained on roads possessing considerable grades, and, consequently, on these roads tend to increase in resistance more rapidly, and thus prevent the most effective operation of the equipment; this condition increases materially the watts per car-mile required on grades where starts are frequent.

In the type of controller under consideration the resistance between the second and third step, R_2 and R_3, being high, is not of much importance in this part of the operation of the controller, provided it is not so high that the car loses acceleration; but if we follow the operation of the controller shown in Fig. 2, it will be noticed that on the sixth notch the motors are connected in multiple, and this second to third step in resistance is again put in series with the two motors in multiple. Here, if the second step is high, the equipment will lose acceleration, and when arriving on the seventh notch the motors will again be subjected to an abnormal flow of current.

It is evident that these conditions can only be determined by the direct measurement of the resistances of these circuits as made by the controller, but the resistances of these circuits possess peculiar features which are not common to a purely metallic circuit. We find contact resistances in the controller, and carbon-brush resistances in the motor. The contacts give extremely variable and unreliable results when measured with a low potential test current. The carbon-brush contact will often appear as an insulator under this condition, and a poor controller contact will give a constantly varying resistance.

In order to bring the contact resistances down to normal it is necessary to pass considerable current through the equipment when testing, and it is most convenient to obtain the current from the railway circuit. But when we use a current varying as the ordinary railway current varies, and yet discover the variation of resistance as low as .005 of an ohm, another difficulty confronts us, and neither a bridge method nor fall of potential method is applicable to this work.

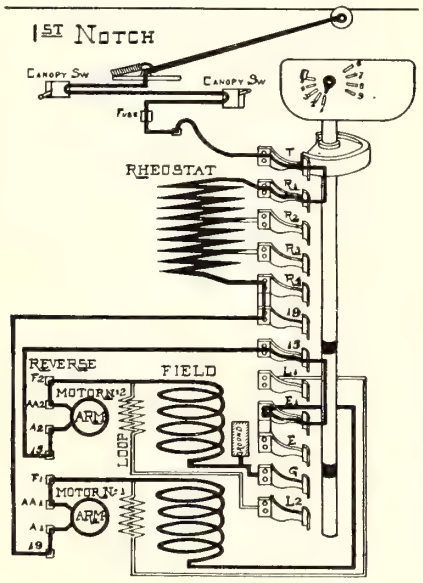

FIG. 1

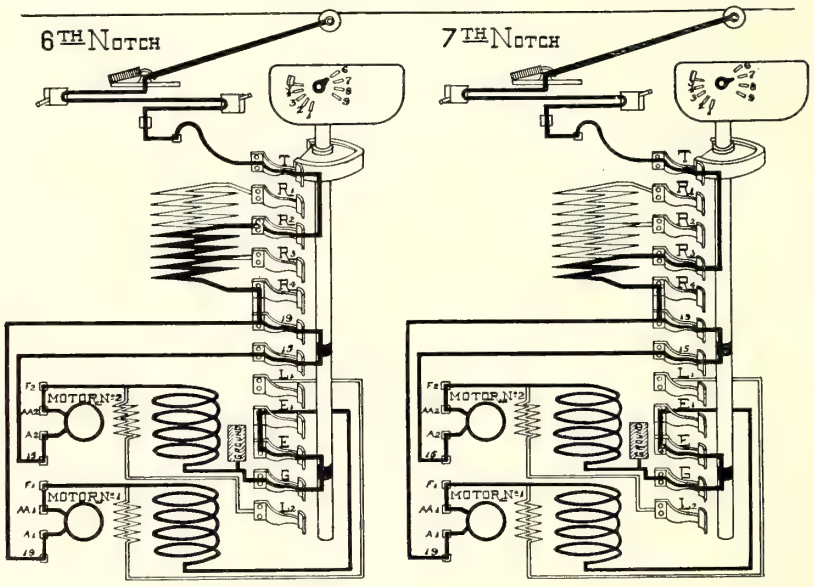

FIG. 2

In any bridge method the measurement of a resistance also includes the contact resistances by which this resistance is placed in the measuring circuit, as at Fig. 3, and due to this varying quantity introduced into the bridge method it is not a reliable instrument under 0.1 ohm, nor at the other extreme can the bridge give quantitative results over 500,000 ohms. For these reasons the method is useless in measuring low resistances with any degree of accuracy which will admit of a definite analysis, especially in those resistances met with in fields and armatures. No multiplying arrangement can increase the accuracy of any measurement external to this instrument.

Thompson's method of measuring resistances, which is applicable to low resistances, is extremely delicate and of general use for this purpose; but there is one very important condition necessary in using this method. That is, there cannot be any appreciable resistance between standard and the resistance under measurement, as at *D* in Fig. 4, for in that condition there would be considerable fall of potential along the measuring lines, which will interfere with the accurate comparisons of the resistances, *A* and *X*, under measurement (and in car inspection it is impossible to have the standard and resistance under measurement adjacent to each other.) The volt-meter and ampere-meter method, where connected as at Fig. 5, will give the resistance sought by dividing the volts read by the amperes flowing. But in measuring an inductive circuit, such as a field or armature of a motor, we find that with the voltage falling the resistance between any inductive terminals is apparently lower than its true resistance, and with the potential rising the resistance will be apparently higher than the true resistance measured. This method is too tedious and unreliable for the purpose of accurately diagnosing equipment troubles, as we have to balance our circuits inductively as well as ohmically in using the trolley circuit in equip-

ment testing; but to make all this practical and of general utility the system must be so devised that the measurements and determinations can be made quickly, and not necessarily by one skilled in the art.

The author, after years of experience, has had to abandon these methods, for they did not produce sufficiently concordant

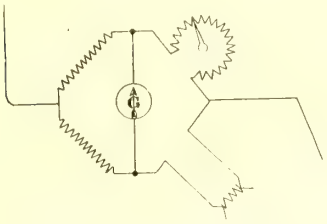

FIG. 3.—BRIDGE METHOD

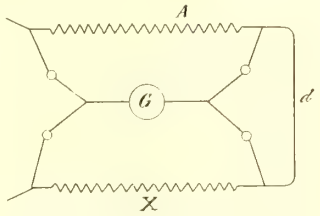

FIG. 4.—THOMPSON'S METHOD

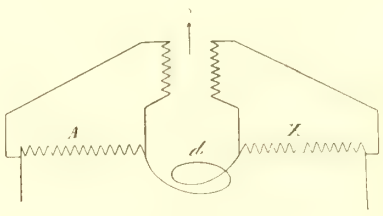

FIG. 6.—DIFFERENTIAL METHOD

results to make the analysis of equipment positive, and he has developed the differential method shown in Fig. 6. This is nothing more than separating the differential coils of Kelvin's method, electrically, so the resistance between A and X would not interfere with the accurate comparison of two resistances.

Another condition necessary in the development of a system is the keeping independent from each other the different tests requiring different connections made to the testing apparatus, so an interlocking system had to be devised by which means the test

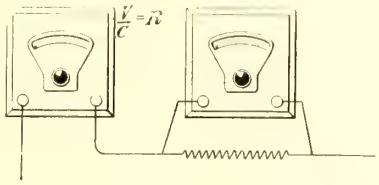

FIG. 5.—VOLT METER AND AMMETER METHOD

under consideration could only be connected up when the dial was turned so the pointer was opposite that test, then the holes for inserting the plugs in this test registered with the proper receptacles, and the plugs could be inserted for this test, and no interconnections could be made which would injure the instruments used in these tests.

The semi-portable apparatus known as form D is shown here, Fig. 7, which combines, besides the inspection tests, all other well-known ampere-meter and volt-meter tests which are required on the line, car operation and electrolysis. The testing set, including only the inspectors' test, is a much more portable affair, and can be readily carried from car to car. It is very easy to make an electrical inspection of an equipment in one minute, when proper arrangements are made to expedite the test, and a testing set can be taken to any part of the road where the cars can be delayed, and this test can be made on each car by holding it for one minute.

The inspection test consists simply of measuring the equipment up on each notch of the controller, and every road fixes its maximum and minimum standard for each type of equipment, there being considerable range at first between the allowable maximum and minimum.

To maintain an equipment means the keeping of the different controller points within standard values, and any part which departs from standard value can immediately be repaired at small cost, before the more serious secondary effects have rendered the equipment a cripple.

I show in Fig. 8 a plotted curve of ten identical equipments which were inspected on a fairly well operated road, and it shows quite a variation in rheostats, and also two burnt-out fields and a poor brush holder. A straight line is drawn through these tests in order to show where the standard should be. It will be noticed that there are high rheostats in several equipments, and it will also be noticed that in equipment No. 2 the high rheostat has resulted in the burning of the field of No. 1 motor. It will cost five times the amount to replace the field that it would to repair the rheostat; and it is only by careful inspection that these primary troubles can be detected in time to prevent a more serious loss.

The ageing effect on the different types of equipments tends to lower in some and to raise in others the resistance of the rheostat. The field resistance will fall slightly, owing to the annealing effect on the wire, but if the resistance falls below 1 per cent it is due to turns being short, or the carbonizing or "baking" of the wire insulation, which allows the current to pass between the adjacent turns through the carbonized cotton insulator instead of around the turn to produce the magnetic effect on the field. The result of this is to make the armature revolve faster in the weakened field, and the armature will become overloaded in its effort to run the car, and also to carry the other motor; in this way if the equipment is operated the result will be an armature burnt out.

In one case where I inspected the cars, the armature winder, who was an excellent worker, had been discharged for the reason that his armatures would not run more than a few hundred miles before being burnt out. I found that defective fields were the cause, and after replacing the bad fields in these equipments the armature winder was reinstated, and there has been no trouble since.

An undiscovered baked field is one of the most prevalent causes of motor troubles. A number of methods of winding and treating fields are now in use, which have for their purpose the preservation

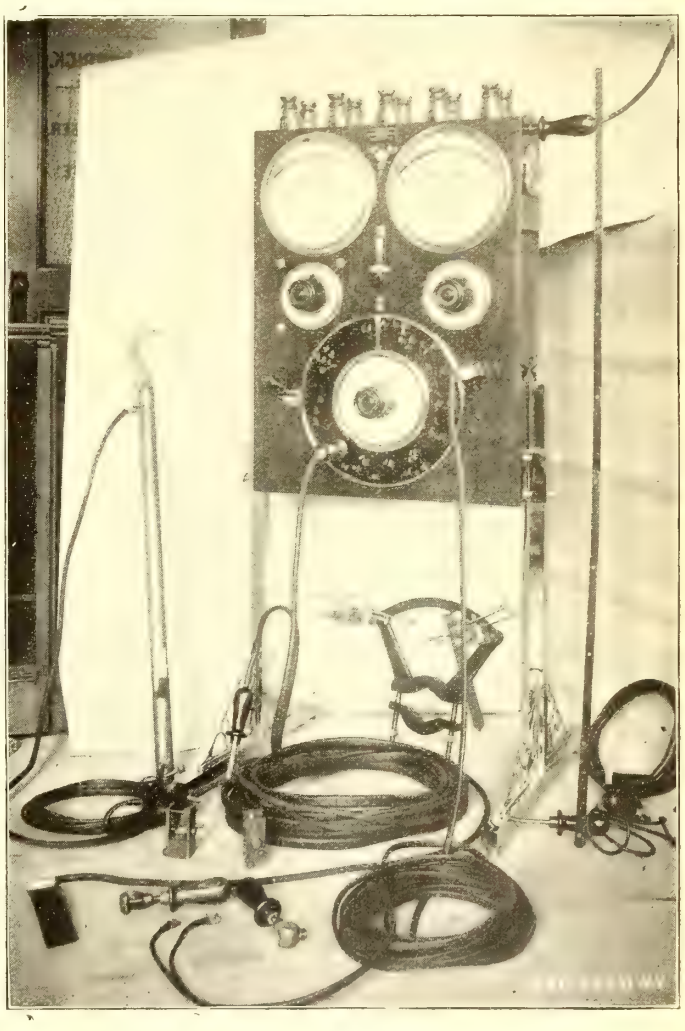

FIG. 7.—TESTING SET

of insulation between adjacent turns of wire, such as winding the wire with asbestos under the cotton. Care must be exercised in using this wire, as some of the forms will not hold the proper number of turns with this increased size, due to the asbestos covering, and if the proper number of turns are put on the form the field spools will not fit in the motor.

Another method used is to slush these coils as they are being wound or to dip them, after they are wound, in a solution made up of chalk, magnesia-oxide and water to the consistency of whitewash. This foreign material, when introduced into the winding

and baked, hardens and forms a mechanical barrier between the adjacent turns and prevents their short circuiting.

Other methods are practiced, such as dipping the field coil into varnish or insulating compounds. These different methods all have for their purpose the introduction between the adjacent turns of wire of a noncarbonizable insulator.

The field coils must be well baked after the application of any of these methods in order that any moisture or alcohol may be driven off before the coils are used. It has been the practice to pass current through these coils and heat and bake them in this way, but when water or alcohol is present internal electrolysis is set up, which forms internally a conducting copper salt, and this destroys the insulating properties of the mediums employed. Another point may be mentioned here in regard to baking where armatures and fields show low resistance to ground after being baked. The baking oven is often completely inclosed, and any moisture excluded from the coil is held in the air; a baking device of this kind, which has no ventilator, is really a steam box, and not a baking oven, and high insulation cannot be obtained unless ventilation to the oven is provided.

The best way to measure the temperature of a motor is to measure its resistance when hot, and for each degree centigrade rise in temperature of the field the resistance will increase 0.38 of 1 per cent. Fig. 9 gives the increase of resistance for each 0.1 of an ohm to 1.5 ohms, and up to 100 degs. centigrade. The drop in volts across one field when the equipment is running is the best method of testing whether the two motors are taking their loads equally when they are connected to a series parallel controller. When the motors are in series they are both taking the same current and the drop across the field should be reduced one-half when the motors are thrown to multiple, and the same current passing in both cases. If, under this condition, the voltage drop is not cut in half the motors must be out of equalization, 8 per cent being the maximum difference in equalization allowable. With the differential method each coil takes the drop off of one field of each motor, and the hand stands at zero in case of equalization. If the hand departs from zero as the speed of the equipment increases the lack of equalization is due to difference in air gaps of the two motors. If there is a constant deflection for all speeds, the non-equalization is due to the unequal resistance of the two motors in multiple.

In the tests on the armature and its commutator, which are the most delicate part of the equipment, the first succumbs to ill usage or lack of proper inspection of the equipment. The different diseases met with in this part of the motor are grounds, short circuits, open coils, broken leads, broken down insulation in the commutator, and especially short circuiting through the commutator ring. Their detection is rendered easy by a bar to bar test on the armature. Fig. 10 shows the method of applying this test to the armature; a brush-holder yoke is clamped to the shaft of the armature, and insulated brushes bear on the bars of the commutator; by moving these brushes around the commutator the indication of the instrument will be constant in all positions of the brushes; but if an armature is wrongly connected there will be a

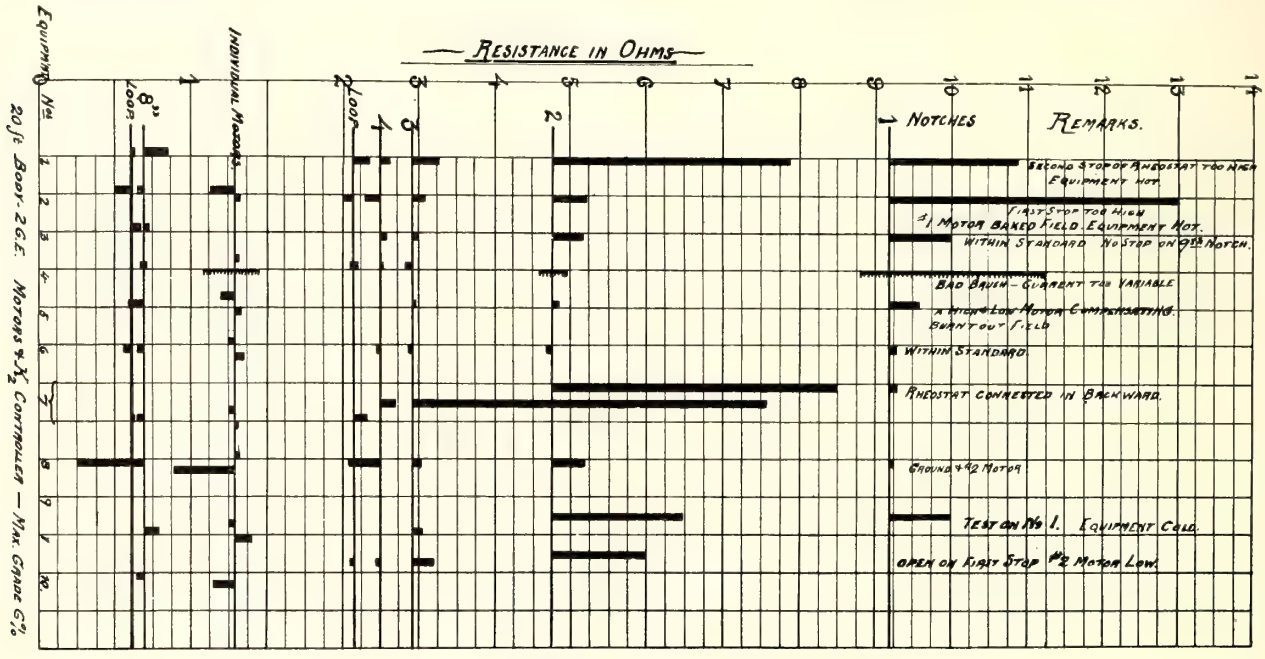

FIG. 8.—RESULT OF TEN DIFFERENT TESTS

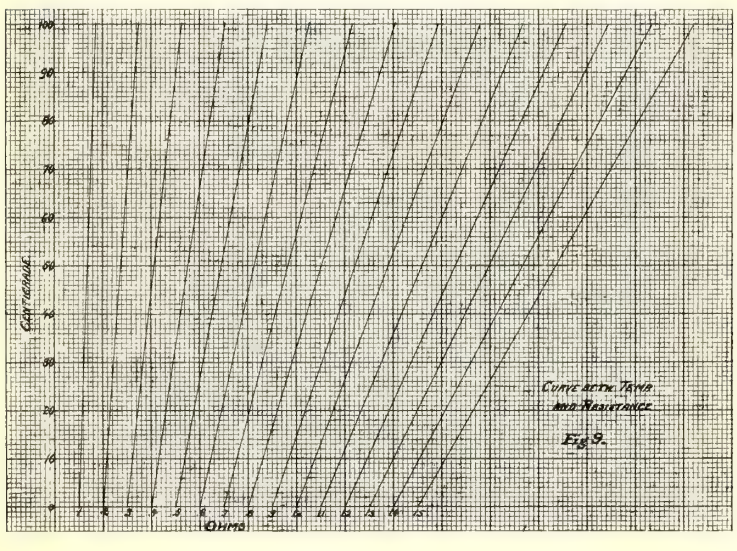

FIG. 9.—TEMPERATURE AND RESISTANCE CURVES

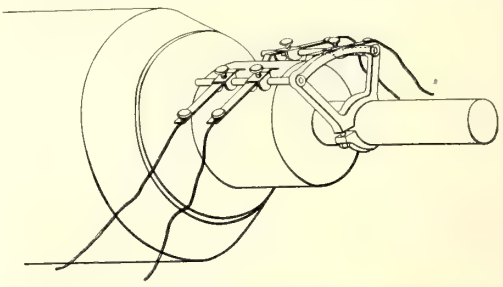

FIG. 10.—METHOD OF TESTING ARMATURE

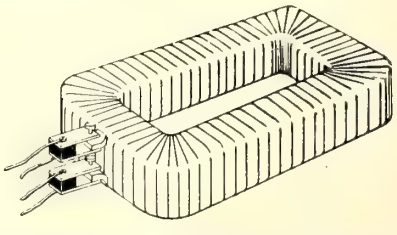

FIG. 11.—METHOD OF CONNECTING TO FIELD COIL

change in values when the brush rests on that commutator bar to which the misplaced lead is connected. Two bars which are short circuited together will give readings lower than normal when they lie between the four testing brushes. A ground on an armature can be located when one of the measuring terminals is connected to the shaft. The grounded coil connects to that commutator bar which gives the lowest reading on the measuring instrument when the measuring contacts are revolved around the commutator. Where the insulation is to be measured the same connections are kept on the armature as for ground, the test plugs are removed, the dial turned to insulation test, and plugs inserted in the exposed receptacles; the insulation is then read directly in megs. on the insulation scale of the instrument. Fig. 11 shows the method of connecting to the field.

The controller has troubles of its own, such as poor contacts of the fingers, short circuits between fingers, grounds, burnt-out segments and misconnections; the insulating partitions between fingers also may become carbonized and cause an arc which destroys the contact fingers. Many imperfections in the controller circuits leave their imprint on the controller. Several of the most prevalent indications will be mentioned, such as the burning of the second resistance contact and an open connection in the first resistance step, indicated by the first resistance contact being bright. A bad flash at either loop contact; where the loop is cut around the field, indicates an open or poor field connection. In this way many things can be observed in connection with the equipment, and it requires that a successful inspector be keenly alive to all the little external evidences of the internal troubles. To aid him I have produced diagrams of connections, divorcing the essential apparatus of the equipment from the intricate wiring system, so that the conditions of cause and effect can be quickly arrived at.

The controller diagrams that we have studied in Figs. 1 and 2 are two of five different types. Placing them historically, we have, first, the rheostat control, which consists of a resistance in series with one or two motors, as the equipment requires. The function of the controller in this case is to close the circuit and vary the resistance in series with the motors, and in this way control the current delivered. The next step in the art of equipment regulation was to first place both motors in series, and also in series with the resistance; after this resistance is cut out the motors are automatically placed in multiple. At this point there is a divergence in connection, one type, such as the *K* controller, places part of the resistance in series with both motors in multiple. The type known as *G* controller, in passing to the multiple position, places one motor directly across the line potential, and the full resistance in series with the other motor, which is cut out in the succeeding notches of the controller, until both motors are directly across the line. The type known as No. 14 controller has a separate resistance step in series with each motor; when the motor is in series these resistances are cut out alternately, both in the series and multiple positions of the controller. Type *C* controller comprehends somewhat the same general arrangement, the relation of the parts only differing in reference to the controller contacts. Each of these controllers has its peculiarities, but to go into them in detail would require too lengthy a discussion.

The wire for car wiring has not been selected large enough in those circuits which lead directly from the motor to the controller. Due to the circuitous route that the current takes in a two-motor equipment with a 20-ft. car body, the length of this circuit is 217 ft., which of No. 6 wire gave under the condition of equipment tested 12 volts drop in this circuit only. This drop occurs under the conditions when the motor requires the maximum potential delivery at its terminals, and a few additional dollars spent in the internal wiring of a car would accomplish the same results as hundreds of dollars spent on the line.

The application of electrical inspection of equipments brings out some very queer conditions caused by the car wiremen not fully comprehending the wiring diagrams furnished. In one case I found a number of equipments with both loop boxes connected in series around the fields of one motor. In another case I found all the rheostat boxes connected in backwards; that is the low resistance step connected to the first step and the high resistance step cut out just before the motors were put across the line. In another case of No. 14 controller I found that one resistance had always been short circuited by a misconnection, and the equipments had been working under this connection for several years.

Briefly summing up my experience of the testing of over a thousand equipments, including nearly all types extant, I find the principal weak points are, first, the two-way connecters are responsible for a great deal more than their share of trouble, and that every break in the continuity of the conductor system reduces their liability of the equipment for continuous operation. Second, that a motor is not any better than its field. Third, that careless brush inspection is responsible for more burnt-out armatures than those caused by poor motormen. Fourth, that the maintenance of an equipment is much more economical and satisfactory than trusting to Providence and awaiting the time until it breaks down; in other words, it is far better for a street railway manager to operate a sanitarium for his equipments than a hospital.

The vitality of an equipment rests entirely upon the excellence of its insulation, and the trend of recent improvements in the equipment is to abandon those insulators which in time either oxydize or carbonize and become conductors.

One final point I would like to mention in regard to high potential alternating insulation tests for railway apparatus. This is generally considered a satisfactory method, because it shows so many faults not indicated by other tests, but the application of this high potential method, with depleted insulation, usually develops the fault which it detects, and curtails the natural life of armatures and fields.

A Large Suburban Car

The Pennsylvania Traction Company of Lancaster, Pa., is one of the largest suburban roads in the State outside of the Philadelphia interurban lines. The practice of the company is especially interesting, because it has tried many different kinds of cars, with a view to finding out which will accommodate its heavy traffic to the best advantage. It is also interesting as showing the general direction or tendency of electric railways in the matter of car construction and design. The car is 28 ft. long and 38 ft. 8 ins. over all, built by J. G. Brill Company. It has curved sides, and is 7 ft. 5 ins. wide at the sill, and 8 ft. wide at the posts. The platforms are 4 ft. 6 ins. long, and the height to the sill from the head of the rail is 30 ins. The step is 17 ins. from the head of the rail, and has a 12-in. riser to the platform.

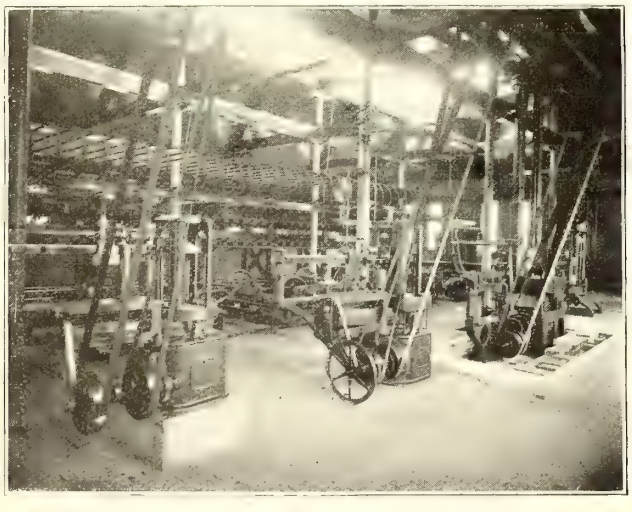
LONG CAR—LANCASTER, PA.

Each end of the car is provided with a stationary round-end vestibule, with doors folding against the vestibule. This is a complete inclosure, and there is no entrance to the car until it has stopped. The completely inclosed vestibule incidentally increases the profits of the road by encouraging riding through the winter weather by making it perfectly comfortable.

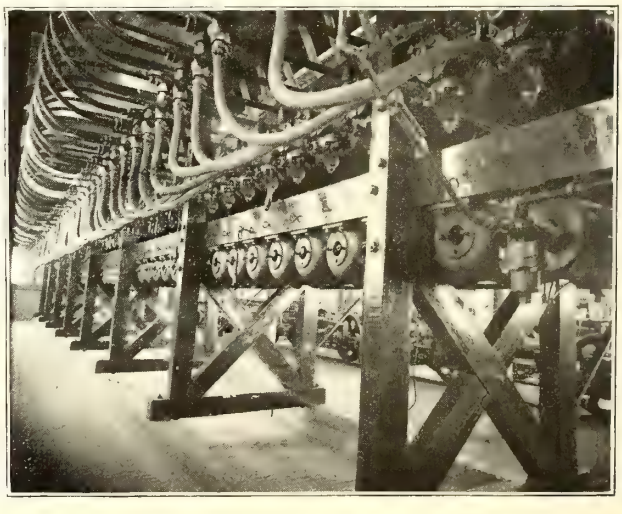
The car is mounted on Brill Eureka maximum traction trucks. The wheel base is 4 ft. and the wheels are 33 ins. and 20 ins in diameter. There are two Westinghouse No. 38 motors. The gage is 5 ft. 2½ ins. The car is furnished with twenty reversible-back seats, covered with spring rattan. This gives a seating capacity for forty persons. The inside finish is of cherry with bird's-eye maple headlining. The trimmings are of bronze throughout. There are two electric headlights and two Brill sand boxes. The buffers are of the Brill angle-iron type. The weight of the car without motors is 20,500 lbs. The trucks weigh 3500 lbs. each.

Testing of Apparatus at Purdue

The engineering laboratories of Purdue University have recently been augmented by the addition of a new room, measuring 50 ft. x 100 ft., in which is installed an experimental equipment of considerable importance. The apparatus is, for the most part, devoted to railroad testing in some of its numerous branches. One of the larger pieces of apparatus is the Master Car Builders' brake shoe testing machine, shown in Fig. 1. This machine was built in 1893 at Wilmerding, Pa., for the M. C. B. Association, and has recently been deposited at Purdue, where the future work on brake shoe testing will be done. Several notable series of tests have already been carried out on the machine by committees of the M. C. B. Association, the results of which tests have been published in its proceedings. The machine consists in its elements of a standard car wheel mounted on a shaft to which is keyed a large fly wheel, designed so as to possess at any speed a kinetic energy of one-eighth of a loaded 60,000-lb. freight car. The shoe to be tested is applied to the car wheel by means of a series of levers, so arranged as to produce between the shoe and the wheel the different pressures actually employed in service and emergency applications. Attached to the head which holds the shoe is a recording dynamometer, arranged to give a continuous record of the tangential pull of the shoe on the wheel. The recording mechanism is also provided with means for registering the speed of the periphery of the wheel, and connection is made with a chronometer for taking the time record. In making tests the double engine, shown in the illustration, is connected with the fly wheel by means of a clutch, and the wheel brought to the desired speed. The clutch is then thrown out and the levers connected with the brake shoe are tripped, thus bringing the shoe in contact with the wheel. The wheel is thus brought to rest in precisely the same manner as the car would be stopped on the road. The data derived from the machine serve to determine the relative coefficients of friction of different shoes under different speeds and pressures of application.



Another unique piece of apparatus is the air brake testing rack, also belonging to the Master Car Builders' Association. This rack, shown in Figs. 2 and 4, was until recently located at Altoona, Pa., and is the one upon which the notable tests conducted by the M. C. B. Association were made. This rack has been deposited at Purdue, and future shop tests of air brakes will be made at that institution. The rack consists of a complete equipment for a fifty-car train. The triples, reservoirs and cylinders are in duplicate. Referring to Fig. 4, the hose pipe shown in the illustration as connected with the upper row of triples can be disconnected and connected with the second set of fifty triples, which may be applied to the lower row of reservoirs. All the fittings, such as angle cocks, hose couplings, drip cocks, etc., found upon a fifty-car train are made a part of the train line, so that the action of the triples on the last reservoirs of the rack will be similar to that found upon an actual train of cars. The plant is provided with recording devices arranged to accurately register the time of application of the brakes in different portions of the train.

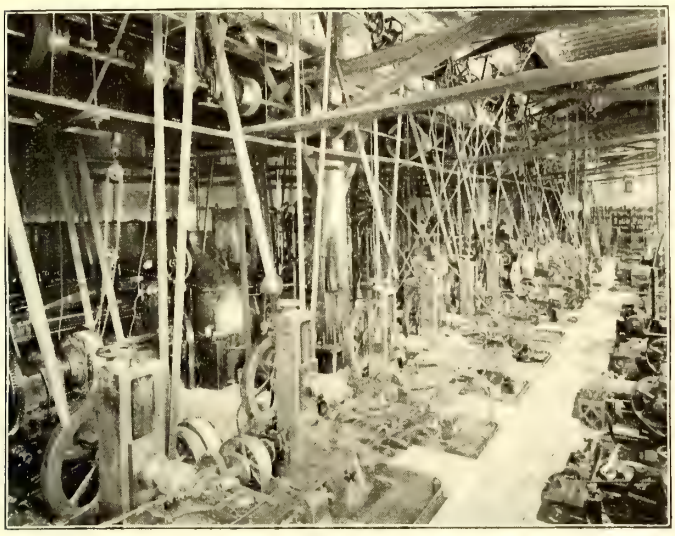


BRAKE SHOE DEPARTMENT

AIR BRAKE DEPARTMENT

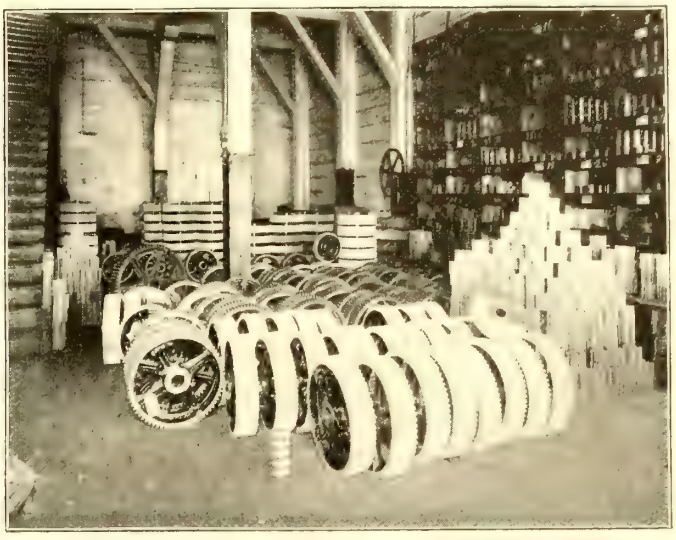
MACHINES FOR TESTING STRENGTH OF MATERIALS

BRAKE TESTING RACKS



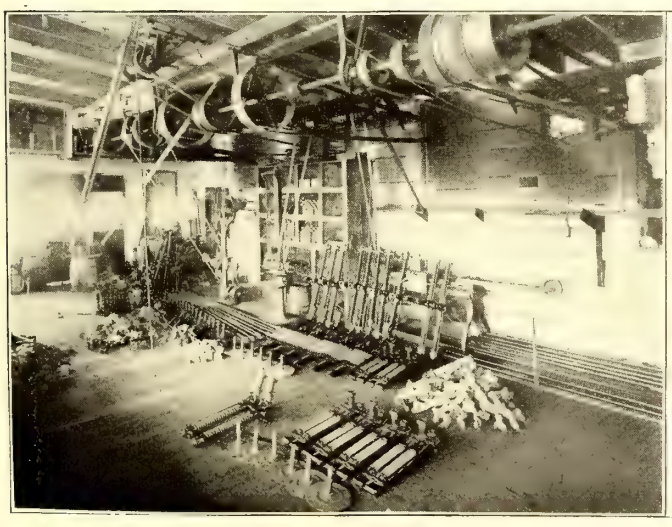
In another portion of the room are located testing machines ranging in capacity from 600 to 300,000 lbs. and adapted for the testing of iron and steel, wood, stone, cement, wire and brick. This portion of the laboratory is shown in Fig. 3 Provision is also made for, and a good deal of work has already been done in the testing of various elements entering into car construction, such as brake beams, truck and body bolsters, truck frames, etc. Among other interesting pieces of equipment may be noted a full-sized model, consisting of cylinders, smokebox and stack of a Richmond compound locomotive; this model was exhibited at the 1897 Master Mechanics' Convention, and there attracted a great deal of attention. There are also interesting and valuable exhibits of freight and street-car trucks, among which are three Brill and one "Lord Baltimore" trucks, couplers, brake beams and interlocking apparatus.

Motor Gears and Pinions

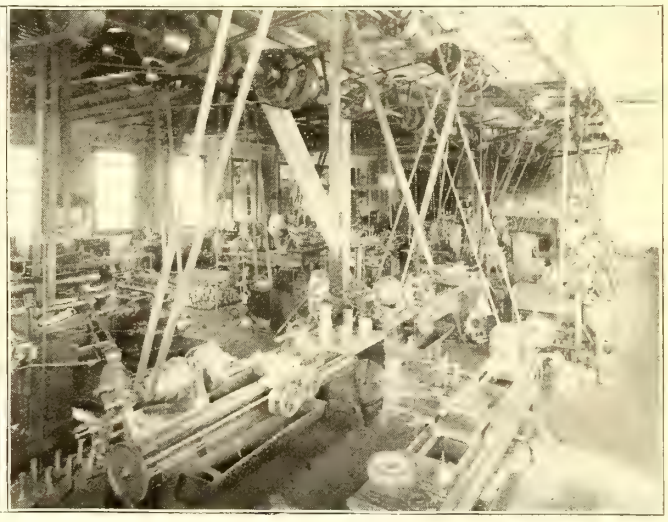


There are few industries allied to industrial traction that have grown into greater magnitude than the making of gears and pinions for street railway service. The users of machinery and appliances of any kind are naturally interested in knowing how the machines they buy are built, of what material, and the capacity and reputation of the establishment engaged in their manufacture. This is especially true of the industry of which this article treats, and in this case, is of double interest because it is found, so far as the records show, that the R. D. Nuttall Company, of Allegheny, Pa., was the first outside of the electrical manufacturing companies to engage in the making of gears and pinions. At the suggestion of one of the local street railway companies, this company, before 1890, had undertaken the manufacture of gears and pinions, and soon after began their manufacture for the general market. The business of the concern, however, was started in 1885 by R. D. Nuttall, and was directed to the making of machinery of every description. The present company was incorporated in 1891, and in 1893 came under the present management, F. A. Estep president, J. R. McGinley vice-president and Thos. Fawcus superintendent. The works are located on Grant Avenue, Allegheny, and occupy a two-story brick building, 100 ft. x 80 ft., with a new addition just completed of 60 ft. x 20 ft. This is being equipped with new machinery, not only for increasing the capacity for making motor gears, but for spur and beveled gears of every description. One of the new machines has a capacity for cutting spur gears 15 ft. in diameter up to 24 in. face, and another machine for beveled gears, up to 8 ft. in diameter, with the latest improved milling machines and key seaters, and a Betts turning and boring mill. The new shop is also to be equipped with a 20-ton traveling crane.

It is the motor gears and pinions, however, in which the reader is especially interested, and which will now be followed in detail. The gear blanks are made chiefly of cast steel, although occasionally, when specified, cast or malleable iron is employed. The blanks are cast in half circles, being split through the spoke, and the first operation in fitting them for service consists in milling the faces of the halves to an accurate male and female fit, the two halves being fastened side by side to the bed of the machine with the curved side down, so that the milling cutters for both faces are on the same shaft. From this machine the parts go to the gang drills, where holes are drilled for receiving the bolts, by means of which the two parts are united into a perfect gear. In the process of drilling, steel templates are employed, which being clamped to the face of the sections, serve as a guide for the drill. This work, as well as all the different operations throughout the shop, is done by the piece, the workmen receiving a certain price for a certain operation, and, in case of the drilling, one man is able to attend to three machines. Following the drilling, the parts are bolted together, when the hub is bored out to the axle fit. Next, the face and edges of the rim are turned to an exact diameter, and in this operation two classes of tools are employed, on one a broad knife cuts the face and edge of the rim as the blank is revolved, while in another process a milling tool runs against the face of the rim and cuts it down as the latter slowly revolves. Of course it is understood that there are a number of tools for each of these operations, so that a large number of gears are undergoing the same operation at the same time. The blanks are now ready for cutting the teeth, and this process is done on automatic gear-cutting machines, of which there are two different styles, some being of the Gould & Eberhardt type, and others of the Brown & Sharpe make. There are twenty-six of these machines, arranged on two sides of a narrow aisle and all are on the same floor with the machines previously described, together with various machines for other purposes.



In the process of gear-cutting the blanks are set up edgewise across the face of the table, and the cutting tools work on the un-



CUTTING GEARS

A CORNER IN THE SUPPLY DEPARTMENT

TROLLEY SHIPPING DEPARTMENT

MACHINE SHOP

der side of the blank, as it moves back and forth. The practice is to finish one tooth at a time. Although it is possible to cut more than one tooth, the result is less accurate than when only one tooth is cut. In the process of cutting, the milling tools are flushed with a lubricating mixture, which flows in a copious stream from small pipes through which it is pumped from a large tank located in the basement, and to which the surplus is returned by drain pipes.

The blanks for pinions are in all cases forged steel, hammered to nearly accurate size, and the first operation consists in drilling or boring out the centre to fit the armature shaft; next, the surface is turned down to accurate size, when the teeth are cut in the same manner as for the gears, the most accurate measurements being followed in all the operations. When finished, the gear and pinion are mounted on suitable mandrels for testing, and the gears are driven by means of a belt at a high speed forward and backward, to see that there is a perfect mesh of the teeth, so that they will run at high speed without noise. The same test also determines the amount of back lash. The plain surfaces are then painted with white lead, and the rough parts with japanned paint, when they go to the store room, ready for shipment. They are not found, however, in any great quantities in the store room, as the company has never yet been able to keep ahead of its orders to any great extent. A few are noted, however, one lot being the last of a hundred to fill an order from Woolwich, Kent, England, and some others, the last of an order for 200 from a city in Italy, which show the wide range of market to which the works cater.

The output of the works is not confined, however, to gears and pinions, but embraces other street railway supplies, including trolley wheels and harps, which are made by the thousands, trolley poles and bases, journal boxes and bearings, in both babbitt and bronze. The trolley bases manufactured by this concern are known as the Standard, and include five different patterns. In the manufacture of bearings, a shell of malleable iron is generally employed for both the axle and armature bearings. These are babbitted and faced down ready for service. The company manufactures many of its own small tools, and for this purpose a separate room is equipped with a fine line of machines, specially designed for tool making, and in the same room is a specially fine tool, designed for planing the teeth of beveled gears down to an accurate finish. Other operations consist in finishing the bolts for side bars of the trolley bases, and the threading of bolts for uniting the parts of the gears. The blanks for the parts are bought from the manufacturers, but the thread cutting is done in the company's shop, for which purpose a number of bolt and nut threading machines are employed.

The wood-working department, including the pattern shop, is located on the second floor, and is provided with the usual equipment of wood-working tools. On the same floor are the offices of the company, while the engine and boiler room occupy a section of the first floor. A 100 h.p. Phœnix engine serves to drive the shafting on the first floor, and a Westinghouse 35 h.p. engine that on the second floor. There is, as well, a lighting generator, incandescent lamps being located about the various tools, an essential feature, as the works are required, generally, to run night and day to keep up with the orders, a double shift of hands being constantly employed. The capacity of the works is about one hundred gears and pinions a day, besides the other appliances above noted, and the employees number usually about one hundred. The affairs of the company are under the immediate direction of F. A. Estep, president and treasurer.

Collection of Blanks and Forms of the Accountant's Association

W. B. Brockway of Toledo, Ohio, secretary of the Street Railway Accountants' Association, has announced that the department of blanks and forms of that association has progressed so far that it is almost in a state of completion, but is being held open for about thirty days in order that those companies who have not already done so may be enabled to contribute their blanks and forms, as requested in a circular letter mailed from the association headquarters on Nov. 15, 1898. As this department gives promise of becoming an important factor, it is hoped that prompt attention will be given to this appeal so that the collection may be absolutely complete.

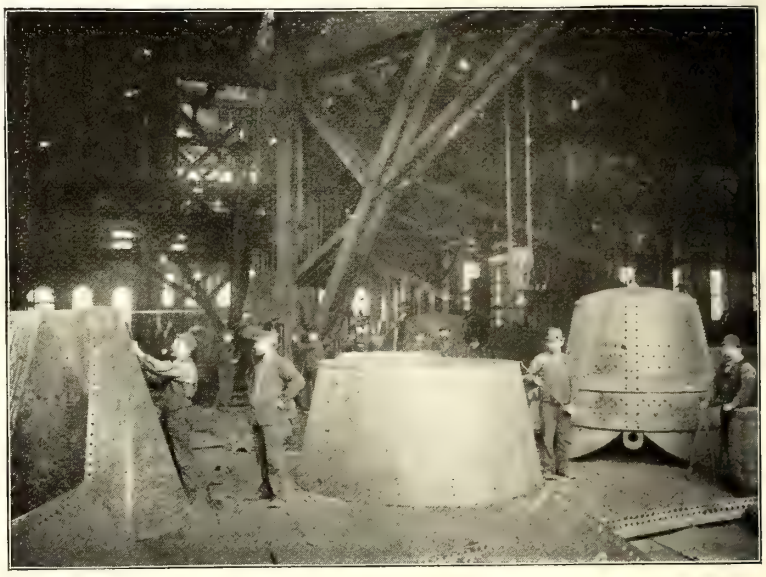


Plate and Structural Work of Steel

Although several years have elapsed since steel in plates and in bars has been employed in structural work, or for smoke stacks, smoke flues, water and oil tanks, gas holders, etc., the actual manipulation of the material is still a new industry to most people. This is not to be wondered at, however, for the products have such a wide application and the manufacturing establishments are necessarily of so great magnitude and so few in number, that unless one is in the market for some one of the various products to which steel readily lends itself, he is not particularly interested in viewing a tank, a cold storage bin or even a towering stack.

One of the largest firms engaged in this industry is the Riter-Conley Manufacturing Company, of Pittsburgh, which, in addition to its construction work, maintains a corps of expert engineers for the purpose of designing and giving expert advice on all questions of economical construction.

The works of the company occupy two plants, one in Pittsburgh and the other in Allegheny. In both about 30,000 tons of sheet and structural steel are consumed annually, and about 1200 men are usually employed. The Pittsburgh plant occupies three buildings, each extending through a block. The first fronts on Water Street, facing the river, and extends through to First Avenue, while the second, a large brick and steel structure, has 240 ft. frontage on First Avenue, reaching through to Second, and the third extends from Second to Third Avenue. The tank department occupies the Front Street building, in which are also located the main offices and designing rooms. To this department the plates are delivered by wagons, the material being purchased for the most part from the neighboring steel mills, or mills in the vicinity of Pittsburgh. The leading tools consist of punches, shears, drills, bending rolls, hydraulic flangers, pneumatic tools and cranes. Of these what are known as rack punches are of special interest. These are fitted with a table to which the metal sheets are attached, and being adjusted to the punch, the sheets are advanced a notch at a time, so that a row of holes equally spaced are punched along the entire edge of the sheet without any attention being given to centering or adjustment. At the last hole, at a corner, the sheet is swung around the punch as a center until the holes are complete on all four sides. In the same building is a blacksmith department, in which the hand flanging is done. Here the most difficult elbows and bends are designed, the workman showing marvelous ingenuity in forging the plates to accurate fit. Air and hydraulic riveters are located at intervals through the works, one a vertical machine, on which flues or tubes, 35 ft. in length and up to 8½ ft. in diameter, can be riveted in single sections, the shell being supported by block and fall from a tower and lifted by hydraulic power. There is also a pneumatic reamer which is attached to the long arm of a jib crane by means of a trolley wheel, so that it has a range of 18 ft. in every direction,

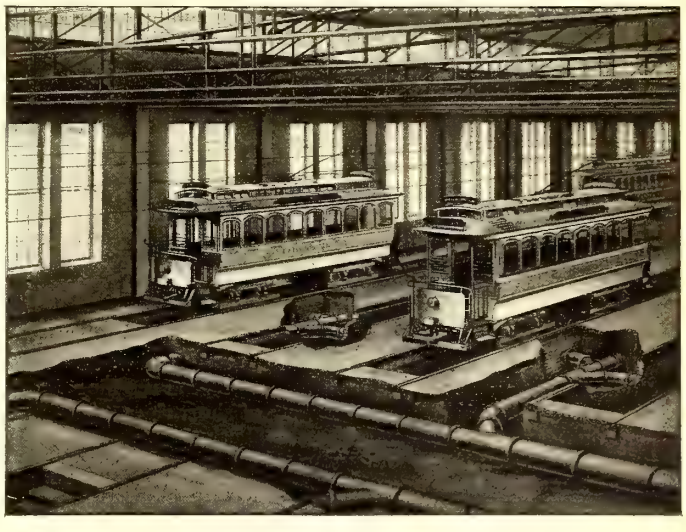
One set of bending rolls is 21 ft. in length, and is driven by an independent steam engine. Passing by the jib cranes, we come to a gang punch, an enormous machine which is capable of punching at one stroke sixty 13/16 in. holes, in ½ in. steel plate. The punches are ranged in three rows and have capacity of receiving

MAKING 40 TON LADLES

a sheet 8 ft. across. The most powerful tool, however, is a 150 ton hydraulic flanger, which has a movable bed plate 10 ft. in diameter, and which will receive plates of the same size. In this machine the upper bed is stationary, while the table is forced up by two enormous plungers, supplemented by several smaller plungers that work through openings in the bed and give a special bend to the plates as may be required. The shipping facilities of the establishment are excellent, as a siding from the Pennsylvania Railroad runs along one end of the main building, where is located a powerful steam crane, by means of which the

CONSTRUCTING A 200 FT. SELF-SUPPORTING STACK

parts or finished structures are readily loaded upon the cars. This concern has during the past year provided structural work for the power and car stations of the Dublin Tramway, of Dublin, Ireland, and more recently has made four smoke flues, each 1000 ft. in length and 12 ft. x 11 ft. sections, for the Metropolitan Street Railway Company, New York City. Among other large orders noted were the material for ten open hearth furnaces, each of 50 tons capacity, for the Alabama Steel & Ship Building Company, to be erected at Ensley, Ala. There was also noted an enormous quantity of riveted steel gas pipe, from 20 ins. to 48 ins. in diameter, designed for a plant in Everett, Mass.



The Allegheny plant is devoted chiefly to the manufacture of structural work and gasometers, and the works occupy seven acres and consist of five buildings, located on Preble Avenue. The buildings are arranged on the four sides of a square, with the power building between. These buildings are known as the receiving shed, are 52 ft. x 175 ft., and from the ends of this lead out the gasometer building, which is 42 ft. x 370 ft., and the structural department, which is 72 ft. x 306 ft. The shipping shed, which is located a little distance from and opposite the other ends of the other buildings, is 60 ft. x 260 ft. Sidings from the neighboring steam railway lead directly into the receiving and shipping sheds. In the former the material is checked up and distributed, the unloading being done by means of an electric traveling crane of 15 tons capacity. This department also included the wood-working branch, in which templates for laying out the work are made. From the receiving shed the material is delivered to the structural department, where it is first laid out from the templates, when, by means of trolley hoists and trucks, it is progressed in regular order to the punches, shears and riveting machines, of which there are a great variety, chief among which are portable air riveters. Some of these are capable of heading a rivet 1¾ ins. in diameter. In this department are five hydraulic jib cranes of enormous capacity. Here are turned out lattice columns and girders and roof structural work of every possible design.

In the manufacture of gas holders, the material is received from the shed as for the other department and progressed in regular stages through the different classes, while in this department, in addition to the punches, are a number of radial drills for making the holes in plates that are too thick for the punches. These are frequently 1¾ ins. in diameter and take corresponding rivets, for the heading of which special riveters are used. Between the main buildings and the shipping sheds is a large area of yard space in which structural work is set up and fitted before shipment, when it is taken down and advanced to the shipping shed, which is of sufficient length for receiving seven freight cars, upon which the materials are placed by means of another traveling electric crane. The company not only manufactures the materials above described, but provides and ships with the products derricks, hoists and other appliances for their erection. The power equipment consists of three engines, the largest of which is 175 h.p. These drive two air compressors of the Rand type, a pump for operating the hydraulic machines and three generators for light and power. The electric power is used for operating three traveling cranes of the Morgan manufacture of fifteen, twenty-five and thirty-five tons capacity and for stationary motors, one of which drives a line of shafting in a gasometer department. As noted above, shipments go to all parts of the world, competing in the price and quality with the reputable high grade products of the old world. In addition to the structures mentioned in this article, the company erects blast furnaces complete, including the hot blast stoves and stacks, stand pipes and towers for water works, penstocks for turbine power stations, grain elevators and miscellaneous work of all descriptions.

The business was established by James M. Riter in 1860, and up to 1873 the work was principally that of steamboat and oil tank construction. In 1873 the firm of Riter & Conley was formed. In 1898 a company was organized under the name of Riter-Conley Manufacturing Company. The affairs of the company are conducted under the direction of the following officers: Thomas B. Riter, president; W. C. Coffin, vice-president; J. S. Craig, secretary and treasurer, and Robert A. McKean, general manager.

The Heating of Car Barns

The extent to which means are being introduced for the heating of car barns is the best evidence of the advisability of maintaining within them a comfortable temperature. They are no longer to be considered as mere storage houses, for the extent to which work is carried on within them converts them rather into work rooms. The process of washing, cleaning, removing snow and ice and making repairs necessitates a tempera-

METHOD OF VENTILATING A CAR HOUSE

ture which will render such work both rapid and comfortable. In barns provided with pits the old method has been to apply the heat locally by stringing steam pipes along the sides of the pits, so as to rapidly melt such snow and ice as may be upon the running gear, and to simplify the matter of making repairs. But such an arrangement is seldom sufficient to also warm the building throughout, particularly along the walls. It is a well-recognized fact that car-house workmen can perform a much greater amount of work in the same time in a warm shop than in a cold one.

For a considerable length of time the hot air feature of the blower system has been utilized in locomotive round-houses and repair shops, the air being discharged directly into the pits, whence it rises, passing on its way through and around the running gear,

and rapidly clearing it of ice and snow. An arrangement of this character, as applied in a car barn by the B. F. Sturtevant Company, of Boston, Mass., is shown in the accompanying illustration. The air in this case is conducted through tile pipes from the central heating plant. This plant consists of a steel pipe heater, made up in sections, inclosed in a steel-plate jacket and connected with the fan, which is driven by an independent engine.

The air is conducted from the main underground pipes through branches and sub-branches to the pits, where it is discharged immediately beneath the cars. The large volume of air which is delivered is sufficient to perform the local work required, and at the same time to effectually heat the whole structure. The deflecting influence of the cars is such that they break up the vertical air currents, and spread them out more or less horizontally, so that the building is well heated at the floor level. By this system a plenum condition is maintained throughout the whole building; all pressure is outward, preventing inward leaks at crevices, and securing thorough circulation of the air. This large supply of hot air, which is a greedy absorber of moisture, keeps the building clear, and rapidly takes up the vapor arising from damp or wet cars.

Compressed Air Cars for New York

The Metropolitan Street Railway Company is making preparations to run several of its crosstown lines by compressed air, notably, the Twenty-eighth and Twenty-ninth Streets line, between the North and East Rivers. Aside from the motive power, the compressed air cars have a number of interesting features of construction, and in their framing are entirely novel. They were built by the J. G. Brill Company, of Philadelphia.

COMPRESSED AIR CAR, NEW YORK

The crosstown lines in New York City below the Harlem River are mostly short, and the traffic, except at the most crowded hours of the day, is composed largely of short rides. The type of car, therefore, to accommodate this business differs materially from that needed in any other part of the city. With compressed air as a motive power, certain changes become necessary in construction, and the result is the car shown in the accompanying engraving. The body is 22 ft. 4 ins. long. The car over the buffers measures 31 ft. 5 ins. It is 6 ft. 6 ins. wide at the sills, and 7 ft. 6 ins. wide at the posts. The platforms, which are not inclosed, are but 4 ft. long. The car stands 27¾ ins. high to the sills, giving a step 14 ins. from the head of the rail. With a low platform, this gives a 12-in. riser. The car is mounted on a No. 21-E truck, and has an 8-ft. wheel base and 30-in. wheels. The gage is standard, 4 ft. 8½ ins.

The whole center of the truck is left open to receive machinery, etc. Three compressed air cylinders, each 9½ ins. in diameter, are to be placed under both of the longitudinal seats, with which the car is fitted. The great wheel base is not a disadvantage of any importance, since these crosstown lines have a very large proportion of tangent. Some of the lines, indeed, are perfectly straight, with the exception of the curves at the switches near the ends of the lines. This feature, of course, makes the long wheel base very advantageous, in fact, because, even with a long body, the car is very steady.

The floor framing of these cars introduces a number of special features. It consists, first, of two side sills of wood, into which two end sills are mortised in the usual way. The side sills are then plated with iron on both sides. The inside plating is turned up at the ends against the end sills, and takes a firm bearing on them. A heavy plate is also put on the outside of the end sills, completely covering the ends of the side sills also. There are in all eight crossings, or cross sills, as they are sometimes termed. Six of these are of angle iron. The two nearest the ends of the car are deep plates turned up against the side sills and bolted fast. All the other crossings are of angle iron carried by malleable iron brackets, which are bolted to both angles and side sills. This form of construction gives an enormous amount of strength and stiffness. In order, however, to obtain good fastenings for the floor and for such attachments as must be necessarily connected to the bottom of the car, each one of these angle iron crossings has a 3-in. "nailing" piece attached to it, and held in place at each end by another malleable angle. These "nailing" pieces are also properly bolted to the angles. The usual diagonal struts are introduced at the ends of the car to keep the frame square.

It will be seen that in this form of construction the wood has been used where its strength can be employed to best advantage, and the metal is introduced in places where wood has naturally its greatest weakness, namely, at the joints. It must be understood that the side sills are only mortised for the timbers at the two ends, thus the whole strength of the wood is preserved. The car body, being very long and having a great overhang, requires an unusual amount of strength to support the long ends, and this strong floor frame was designed to give the required strength.

The springs under these cars were designed to give a very easy motion. The semi-elliptics were made 36 ins. long, not only giving ample support, but making galloping entirely impossible. The side bars of the truck, being under great strain, were made accordingly heavy and stiff, to carry the weight of a heavy car body and the propelling machinery.

There are four folding gates, with solid iron hood supports. The body of the car is, in general, finished according to the Metropolitan standard, the woodwork being selected white ash, and the veneer seat covered with standard Broadway carpet. The ceiling is of three-ply maple, without decoration. The trim inside is all of bronze, and the sash have metal styles. The brakes are of the Sterling pattern.

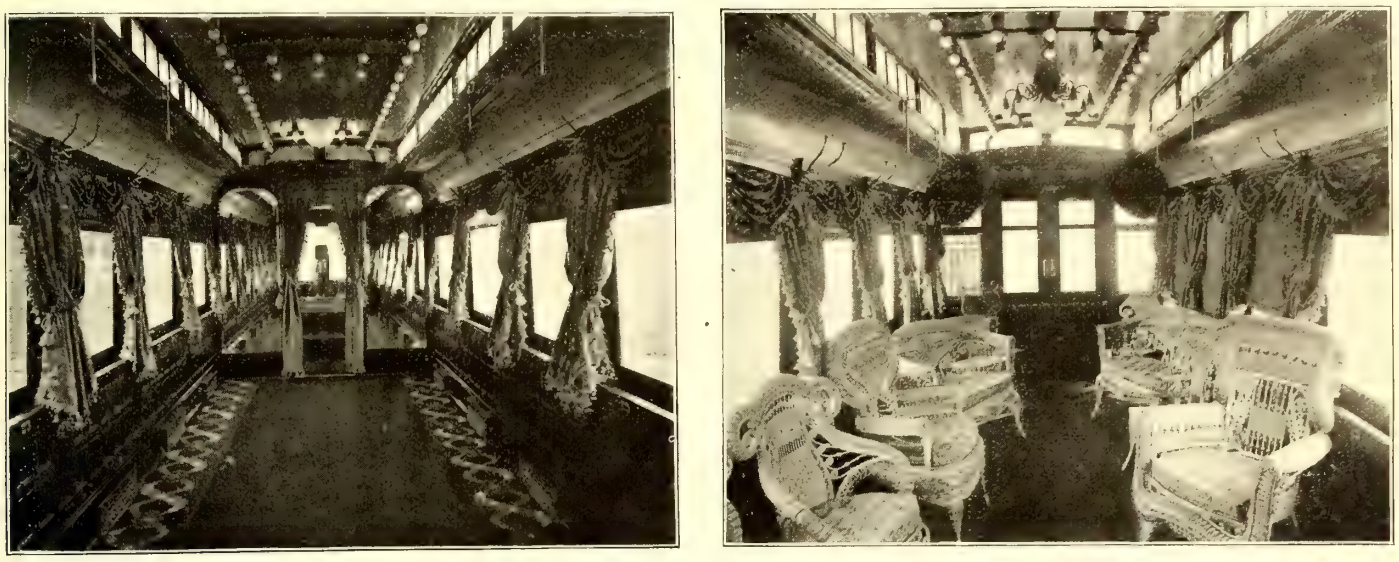
Each of the posts are provided with a push-button for signalling the conductor, and the lighting is done by three Pintsch gas lamps. The body is supported by a deep gas-pipe truss, well anchored at each end of the sills.

Insulating Compounds

The letters P. & B., under which the compounds and material manufactured by the Standard Paint Company, of New York, are issued, continue to be recognized as synonymous with preservative and roof paints, insulating tape, armature and field coil varnish and other insulations, as well as various products of rubberoid, which are manufactured by the Standard Paint Company. This company reports that its business during 1898 in electrical compounds was considerably in excess of that in any previous year since the organization of the company. The sale of this material in Europe is particularly satisfactory, and the P. & B. electrical compounds and armature and field coil varnish are rapidly attaining as high a position in the estimation of electricians there as they have in this country. The branch factory at Hamburg, Germany, has been kept busy ever since it opened at the beginning of 1898, not only in the manufacture of materials referred to above, but also in that of P. & B. preservative and roof paints, building sheathing and insulating papers and rubberoid roofing. The company also states that the orders for P. & B. insulating tape in both Europe and America have for some months past been far in excess of that in any previous time since the company began the manufacture of goods.

Handsome Parlor Car

The accompanying engravings show a director's parlor car recently constructed by the American Car Company of St. Louis for the Baltimore City Passenger Railway Company of Baltimore, Md. The car has elicited favorable criticism from quite a number of railway officials, and the following description will be of interest.



The body is of the swell and concave panel type, 30 ft. over corner posts, with 5-ft. platforms, and is mounted upon high-speed double-motor trucks. The smoking compartment is 10 ft. in length, and the ladies' parlor 20 ft. The doors leading to either compartment from the platforms are of the twin automatic type. The eight side windows are double-sashed, and glazed with beveled crystal polished plate, two windows at the center having large observation lights. Between linings on the inside the car measures 8 ft. in the clear.

The wood for the interior finish is a finely figured East Indian mahogany, known to the trade as Padouk, and was specially imported for this car. It is solid throughout, and a few beaded mouldings and delicate carvings stand out in clear-cut bold relief on the smoothly polished surface, accentuating the rich glowing amber and vermillion tints natural to this species of wood.

The interior lines of architecture are plain, modest and neatly elaborated into the colonial and empire style. The upper deck, being very broad, is recessed into a secondary dome, from which the opalescent center electroliers depend, surrounded and bordered seemingly by a myriad of translucent electric globes encased in bronze gilt husks.

The curtains are of green, silk-faced pantasote, mounted on spring rollers and Acme holding devices. The overhangings, portieres and upholstery are of a luxuriant texture in soft green tints, harmonizing nicely with the Royal Wilton floor rugs. The reed furniture of fantastic designs is stained and tinted to match the general color scheme. Two cheval mirrors are set in massive frames at the further end of the ladies' parlor.

Every convenience conducive to comfort and luxury has been admirably placed and planned. The appointments include adjustable tables for games and refreshments. A folding lavatory and ice cooler, as well as a cosy buffet closet, find place in the smokers' den. The refrigerator, supply chests and tables are carried beneath the car body, being suspended between the trucks.

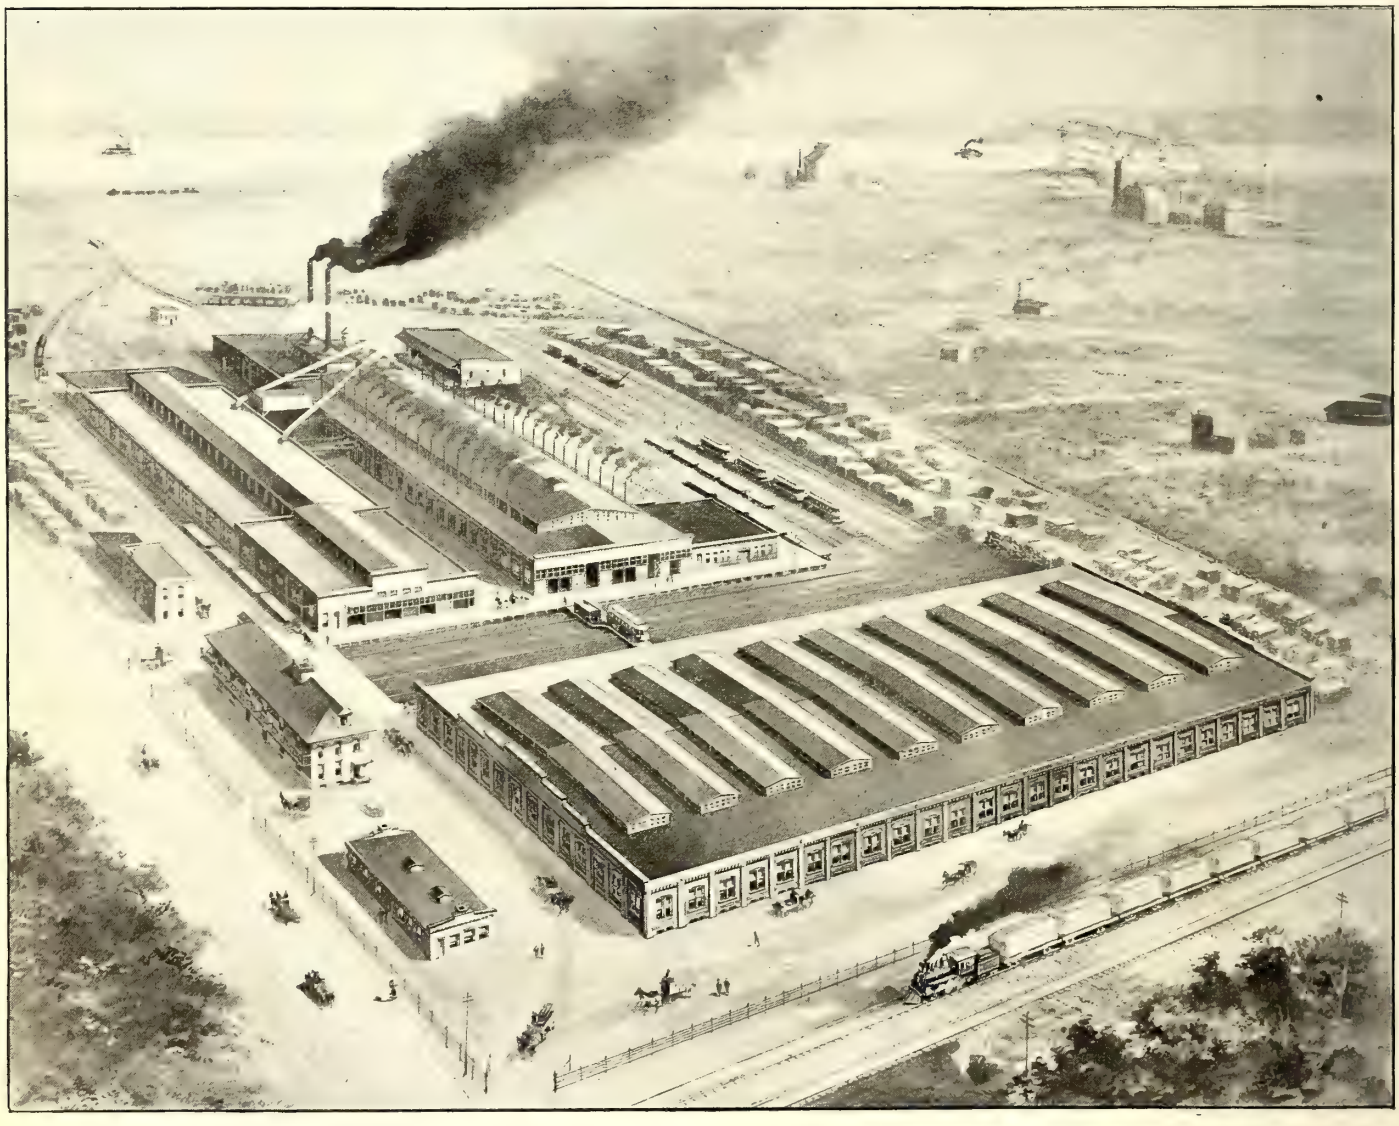
INTERIOR VIEWS OF PARLOR CAR

Twelve electric Gold car heaters are placed in the side walls, and a regulating switch turned to any of three points provides a varying degree of heat. A system of electric call bells is arranged to conveniently summon either porter or conductor, and the latter signals to his motorman by touching a push button. The other motor car accessories are of the latest and best types in use, and were specially manufactured for this car. The hardware trimmings, coat and hat hooks and parcel racks are of gold bronze. The electric headlights are 14-in. copper, silvered reflectors, incased in solid bronze frames.

The platform gates are of solid gold bronze of the grille folding type, and the dashers are capped with bronze and ornamental scroll designs. The exterior decorations of this car are in entire harmony with its interior furnishings. The color is a rich olive, the striping and ornaments gold, the lettering trim and neat. The car is called "Maryland," in honor of the state of that name.

PARLOR CAR, BALTIMORE

Car Building in St. Louis



St. Louis has long held a commanding position in the lumber market, and has been regarded as a center for all lines of industry in which lumber plays a prominent part. Its leading position in the car building industry, particularly that of street railway cars, has long been recognized, and this will now undoubtedly be increased with the new facilities for building cars possessed by the city through the completion of the new works of the St. Louis Car Company.

Ten years ago the most sanguine street railway man hardly dreamed of the coming development of the street railway industry, but the introduction of electricity has so widened the possibilities of street car service that the field to-day offers opportunities to the manufacturer almost equal to those of the steam roads. With 50,000 street cars running on some 1500 different lines in the United States, and with scores of new roads being constantly added to the list, without considering the foreign demand for this class of rolling stock, the necessity of supplying this equipment and replacing worn-out or out-grown equipment has created a competitive interest between the manufacturers, and compelled them to improve their facilities, which were considered more than ample a few years ago.

To this end the St. Louis Car Company, of St. Louis, Mo., has just completed the erection of the new plant mentioned, which is complete in all modern improvements. The works were planned and laid out by an experience born of years of car building, and incorporate every idea for the successful and economical building of street cars.

The site is on the north side of the city on the line of the St. Louis, Keokuk & Northwestern Railroad, at a point convenient to the North Broadway street cars, and covers some twenty acres of ground. The idea kept uppermost in mind in laying out the works has been to so plan every detail that each piece going into the construction of a car will be handled the least possible number of times and, during the various processes which it must undergo, will be carried the least possible distance.

The shops are equipped for turning out everything necessary in the construction of a car. In the rear and to the east of the buildings are the yards for the storing and curing of raw material. These are served with a system of stone ballasted tracks, 4 miles in length, and equipped with four electric motor engines or dummies, power being furnished by overhead electric system. The railroad company connected with the plant is not required to do any switching whatsoever, as all freight cars are moved with the electric dummies and all raw material is handled in this manner. As the various shops are covered with a network of tracks, it is possible to load the material from the yards or directly from the cars, by smaller dummies, which deliver the material to the very spot where it is required.

WORKS OF THE ST. LOUIS CAR CO., ST. LOUIS, MO.

Opening into the yards on the rear are the blacksmith and machine shops and the mill. The mill is separated lengthwise into three divisions; through the first go all heavy materials, such as sills, bottom and platform materials, through the second all heavy irregular pieces, and through the third the lightest pieces. From this shop the material goes to the cabinet shop, each part passing successively from workman to workman and from machine to machine until it reaches the further end completely finished and ready for the erecting shop. In one corner of the mill is a department for sharpening and repairing wood-working tools; one man, with the assistance of several automatic grinding machines, can keep all the shop tools in good condition.

In the blacksmith shop the conditions are similar to those in the mill. Here are lines of forges, steam hammers, presses, bolt cutters, lathes, etc., and each step forward of a piece of material brings it so much nearer to its finished condition. In one end of the

blacksmith shop is the truck department, where the St. Louis Car Company trucks are manufactured. A future article will be devoted to the advantages of these trucks, which are giving the greatest satisfaction. Adjoining the blacksmith shop is the store room; in the rear of the blacksmith shop are the engine and boiler rooms. A right and left-hand engine are coupled together, making a double engine of 750 h.p., which furnishes the motive power for the plant. There is also installed a smaller engine directly connected to an electrical generator for furnishing light and power.

In case of emergency electric motors are distributed in various parts of the mill and blacksmith shop connected with outside Commercial Electric wires, which will enable the work to go on at any time should any mishap take place in the engine room. An air compressing plant is about to be put in, and will be utilized in the construction departments, and will enable a more rapid construction than can be possibly supplied by manual labor.

The boiler room has five fire tube boilers with a capacity of 750 h.p., with a refuse from the mill that will furnish an abundance of fuel in the summer time. The small quantity of coal required in the winter time is maintained at a minium cost, St. Louis being in the center of the most abundant steam coal region in the world.

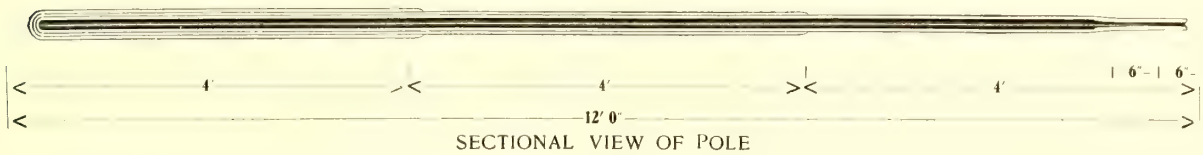
Along the eastern end of the blacksmith and mill runs a wide platform, from the western end of the erecting shop projects a corresponding one, and between these runs a traveling electric table 60 ft. long. The range of this table is the full length of the erecting shop, and it is equipped with block and tackle, and a winding drum; by its means two men can load cars, trucks, or car load of material from any part of the shops and deliver them to any other part. When cars are completed for shipment with motor attachments, they are run out of the erecting shop on to the flat car in two minutes.

The erecting shop is 300 ft. x 624 ft. This immense building is entirely under one roof and contains 55,000 sq. ft. of glass; it is 20 ft. in height, has forty tracks and a capacity for 300 cars. The construction of a car body is started upon small wooden trucks and the car is not moved until it is ready to be shipped. The eastern end of the erecting shop is reserved for the painting department, where panels, head linings, etc., that require to be painted before entering into the car, are given attention. The manufacture of car seats, which is a special feature of this company, is also carried on in a part of this large building. The painting department is equipped with all modern improvements, and equal to any set apart for that purpose. A small building to the west of the erecting shop contains the storage room for oils, varnishes, etc.; the machinery here for grinding and mixing pigments is operated by a small electric motor.

The buildings are all of brick with composition roof, are made to afford excellent ventilation, and throughout the shops are distributed 1100 incandescent and 75 arc lights.

The blacksmith and machine shops are heated with a hot air system which will raise the temperature from zero to 60 degrees in an hour. In the erecting shop, the largest single building on the place, is installed the Warren Webster exhaust steam heating system. By its use it is possible to heat the entire building with exhaust steam with an atmospheric pressure and down to 3 in. of vacuum, that in the very coldest weather a comfortable temperature can be obtained, and with the additional advantage that no dust can interfere with the painting in this shop. The system requires 50,000 ft. of 1½-in. pipe, and is one of the most improved methods of heating, and at the same time the most economical.

The general offices adjoin the shops on the west. They are large, commodious, elegantly furnished. The doors, railings, fittings, desks, chairs and every article of furniture are of mahogany and in every way modern and up to date. On the second floor of the office building is the draughting department and the photographic department. The latter is completely equipped with all modern photographic appliances, dark room, etc., and every car built is photographed. A telephone system connecting all departments with the office is one of the many convenient arrangements of the new plant.



For the purpose of delivering its products the St. Louis Car Company has one hundred 60-ft. modern flat cars, which are operated over all the railroads in the country, and are especially built and designed for this service. Within the last year these cars have been loaded with street cars for almost every important city in the United States, and the foreign shipments of the St. Louis Car Company have been to Germany, England, Ireland, Brazil and various South American ports.

Cold Drawn Seamless Steel Trolley Poles

The use of cold drawn seamless steel tubes for structural and other work has demonstrated so clearly the strength of this material that railway managers have been interested in learning the application of this material to trolley poles. The accompanying engravings show a pole of this character manufactured by the Shelby Steel Tube Company of Cleveland, Ohio. The pole is built up of three pieces of cold drawn high carbon seamless steel tubing, which are put together in the manner shown in Fig. 2, after which the surfaces are cold welded. This makes, it is claimed, a pole having a maximum amount of strength with a minimum weight, and one which will meet all requirements without accident and delay in traffic.

SEAMLESS STEEL TROLLEY POLE

SECTIONAL VIEW OF POLE

Spiral Springs

One of the oldest establishments in the United States for the manufacture of spiral springs is owned by Miller & Van Winkle, of Brooklyn, N. Y. For about thirty years this firm has made steel and steel wire springs for all purposes, and its collection of dies now includes one for almost every form of spiral spring that can possibly be required.

The springs manufactured by Miller & Van Winkle go into a large variety of industries. Among the standard forms carried in stock in all sizes are trolley springs, packing valve springs, dynamo and motor brush-holder springs, upholstering springs, machinery and electrical springs; also tempered steel wire and flat steel springs. The officials of the firm give as a reason for the steady growth and increase of their business the fact that they give extremely close attention to the purchasing of all materials that enter into the manufacture of their products, an expert being employed to do all the purchasing. The same care and watchfulness are exercised throughout the entire process of manufacture, every detail of construction and workmanship being given close consideration.

As an indication that the Miller & Van Winkle goods give satisfaction, it may be stated that their springs have been in use on the Brooklyn Bridge for a number of years, and several large contracts have also been received from the United States Government.

The Frank Ridlon Company, of Boston, has made an important addition to its force by the acquisition of Charles N. Wood, who has been elected vice-president of the company, and who will hereafter combine his business with that of the Ridlon Company. This latter will, therefore, continue the important agencies in New England which Mr. Wood has been conducting so successfully under his own name, viz., the R. D. Nuttall Company, the International Register Company, the Van Wagoner & Williams Hardware Company, the Bradford Belting Company, the Monarch Stove & Manufacturing Company, the American Electric Heating Corporation, and Wilson, Thomson & Company. It is the intention of the Ridlon Company to establish in this connection and under Mr. Wood's management, a strictly street railway supply business. It will be in a position to fill orders for all street railway supplies, and its facilities for doing repair work and rewinding armatures are the very best. For the time being Mr. Wood will continue his office at 31 State Street, but as soon as the company can obtain commodious offices, of which it has leases at 200 Summer Street, the business will be consolidated in one office.

New Attraction for Street Railway Parks

The demand made by street railway managers for new attractions at parks and pleasure resorts has led a number of companies which make a specialty of supplying attractions of this kind to devise several novel and ingenious arrangements for the coming season for attracting pleasure seekers. Among the most noticeable of these is one furnished by Paul Boyton, of Brooklyn, N. Y., who is one of the best-known inventors of amusement enterprises in this country. His latest idea is known as a "Trip Down the Rivers of the World," and bids fair to rival in popularity the "shoot the chutes," of which he is the inventor.

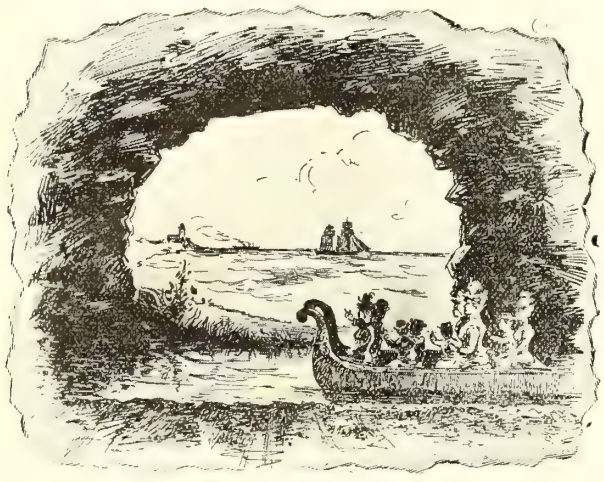


FIG. 2.—VIEW FROM CAVE

This latest attraction consists of a miniature river from 4 to 5 ft. wide and 24 ins. deep, in which is a strong current of water to carry the boats loaded with passengers for a long, cool ride through artificial tunnels, caves and rocky caverns, with openings at intervals, through which the voyagers observe the most pleasing scenery. The river way is built of wood made water-tight, so as to prevent all leakage, and can be made any length, although the best results have been obtained with a length of from 1200 to 1400 ft. The river can be built in almost any sized and shaped lot, but preferably in an oblong space about 100 ft. x 300 ft. A gentle grade is given the river bed by making one terminal about 18 ins. lower than the other. This has been found sufficient to give a fairly swift current throughout the entire length of the stream, and a small 10-h.p. gas or steam engine or electric motor-driven pump is employed at the termini to lift the water from the lower end back into the higher end. In this way the same water can be used over and over again, the only loss being from evaporation.

The boats are sent out without attendants, as it has been found that the current will take them around without any difficulty whatever, and all the employees required to operate the entire attraction are a ticket seller, ticket taker, engineer and two or three men to load the boats and take charge of them at the terminal. The boats are lifted from the lower level to the higher one on rollers. The scenic effects are secured by placing painted screens immediately in front of the openings in the wall along the river. The scenery may be varied, of course, to meet any requirements, and can be changed at intervals at slight expense. A favorite scheme is a representation of a trip down one of the principal rivers of the world, in which the prominent points of interest along each shore are seen. The impression would be, after riding in one of the rapidly moving boats, that a trip of fully a mile or more had been taken, when, as a matter of fact, the distance covered might not be more than a quarter of a mile. The accompanying diagram, Fig. 1, gives an excellent idea of the general arrangement of the river, showing the openings, with scenery screens before them. Fig. 2 shows a possible view from one of the caves.

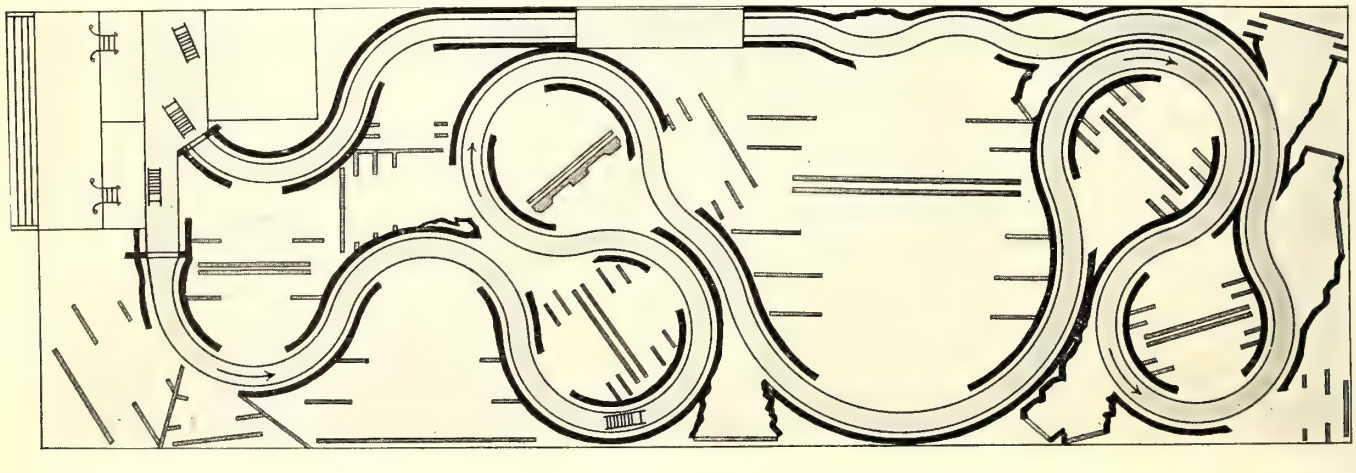

FIG. 1.—GROUND PLAN OF A SCENIC RIVER

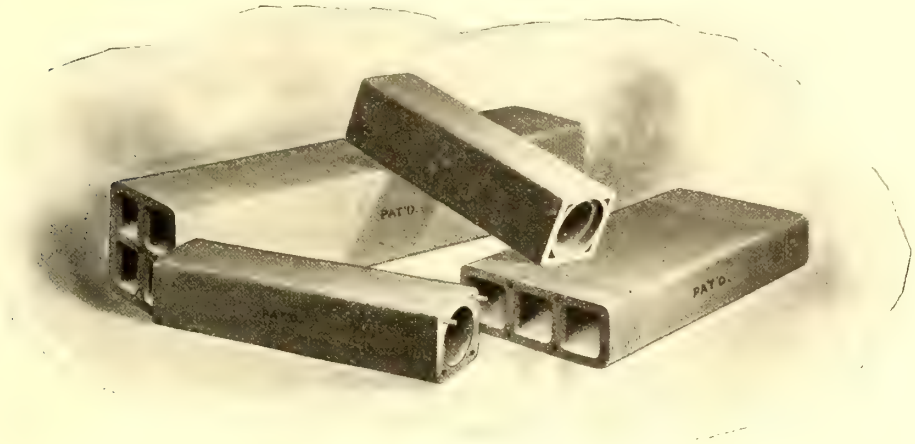
Rolled Steel Gongs

Signal gongs and conductors' bells, cold pressed from steel plate, have been extensively used for a number of years in place of gongs made from cast metal, and there seems to be an increased demand for them. The special claims made for this type of gong are that they are not liable to crack or break, and that the tone is agreeable and can be regulated to any pitch. The Pittsburgh Steel Hollow Ware Company of Allegheny, Pa., is the principal manufacturer of this type of gong, and the gongs are made in all sizes, from 3 ins. to 20 ins. in diameter. The prevailing size for street railway service, however, is 14 ins. The products of the firm embrace in addition to gongs for street railway service, locomotive trip gongs and gongs for fire apparatus. Besides this, the works turn out large quantities of circular coulters, which are sold to the manufacturers of plows and agricultural implements.

The gongs are all pressed or stamped from circular metal plates, which are purchased, already circled, from neighboring steel mills. The peculiar tools employed in the process of manufacture press the metal into shape without forming any wrinkles or kinks, and give a uniformly smooth surface. The company has recently undertaken the manufacture, by the same process, of large church bells and bells for musical chimes, the tone being regulated by the gage of the metal and the amount of carbon it contains. The works of the company are located at Cheswick, 14 miles from Pittsburgh, and occupy two buildings, the principal one of which is 75 ft. x 200 ft., the other a warehouse, which is 25 ft. x 60 ft. The tool equipment is mostly of the company's own design and manufacture, and is of such a character as to enable it to compete in price with any other dealers. The products of the works go to all parts of the world, and as noted above, the demand for these goods is constantly increasing. The works employ about thirty-five men, and have a capacity for turning out 1000 car gongs a day. The company was organized in 1892, and the works are operated under the direction of the following officers: John S. McIntosh, president; Joseph McNaugher, secretary, and J. T. Duff, superintendent.



Electric Railway in Thorn

The electrical equipment of the Thorner Strassenbahn of Thorn, Germany, which was recently installed by the Electricitäts Gesellschaft, Felix Singer & Co., of Berlin, was put in electrical operation Feb. 1. The same company has also undertaken the construction of a new electric line from Thorner to Mocker, as well as the electric lighting station for both cities, and both of these will soon be put in operation.

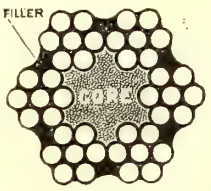
Contracts for Conduits in Baltimore

The board of awards of the city of Baltimore, upon the recommendation of the chief engineer of the electrical commission, Charles E. Phelps, Jr., recently awarded the contract for the entire electrical conduit system for the city of Baltimore to the American Vitrified Conduit Company of New York, of which C. J. Field is general manager. This contract is for several million feet of vitrified tile, multiple duct conduits, the multiple being from 2 to 16 ducts. It was let upon specifications which were very carefully prepared by Mr. Phelps, and on which bids were received for various kinds of multiple and single duct tile conduits, cement pipe, wooden and indurated fibre, etc. The system of conduits about to be installed will include provisions for all the electric light, street railway feeder, telephone, telegraph and other wires throughout the city, and the latest practice in installations of this kind in all the large cities of the country has been carefully studied, and the best points from each adopted.

In addition to this contract, the American Vitrified Conduit Company has on hand a large number of orders, some of them from the leading cities of the country, for conduits of different patterns. Among these are one for several million feet from the Narragansett Electric Lighting Company of Providence, and an order for several thousand feet from the Edison Electric Company and the Western Union Telegraph Company at New Orleans, where some of the most difficult problems in underground construction are being worked out. The same company is taking contracts for complete installation of systems, including all details, where it is desired. The accompanying engraving shows some of the ordinary types of conduits made by this company.

DIFFERENT TYPES OF CONDUITS

A Change of Name



The Falk Manufacturing Company, of Milwaukee, Wis., has decided to drop the word "manufacturing" from its title, and will hereafter be known as The Falk Company. This change is made because one of the most important parts of the company's business is that of acting as engineers and contractors in the building of street railways, so that the word manufacturing does not seem appropriate. With this change of name the company has also been making other important changes, which will result in materially enlarging its facilities for business. During the last month it has acquired the plant and business of the Western Gear Company of Milwaukee, which, as is well known, has been a large manufacturer of street railway gears and pinions. As Mr. Falk, president of the Falk Manufacturing Company, has also been president and a heavy stockholder in the Western Gear Company, the combination of interests was only natural.

The Falk Company has also purchased a large tract of ground about a mile east of its present works, upon which it will immediately begin the erection of three large buildings for steel foundry, machine and blacksmith shops. The buildings will be entirely of brick and steel, equipped in the most modern manner, with open-hearth steel furnaces, electric traveling cranes, compressed air, etc. All of the machines will be driven by the independent motor system, doing away with pulleys and shafting. The company will add to its business the manufacture of steel castings for all purposes, and will also enlarge and improve its special work department. While pushing energetically the work in its manufacturing and construction departments, the company will be even more active than heretofore in the field of cast-welding, and in efforts for improvements in that direction. As stated previously, the company will appeal from the recent decision of the United States District Court in St. Louis adverse to one of its patents, and will also vigorously defend its rights in all of its other patents.

The additions to and reorganization of the company's business mentioned above have also brought about some changes in officers. Mr. Falk and Mr. Wurster will continue as president and secretary and treasurer, respectively, while Mr. Smith, who has been general superintendent and engineer of the company, will be vice-president. Adolph Quentin, late vice-president of the Western Gear Company, will be second vice-president of the Falk Company, and Charles L. Jones, secretary of the Western Gear Company, will be assistant-secretary of the Falk Company.

Preservation of Wire Ropes

The acquiremnt of a material for treatment of the manila or jute core in the process of manufacture of wire ropes possessing pliability, lubricating and waterproof qualities, and free from destructive acid, has been diligently sought by wire-rope manufacturers. There are numerous places where wire ropes are liable to become water soaked almost immediately after installation (where not specially prepared to resist moisture), such as cable railway service, wet mines, dredging machinery, power transmission, and in many other places of exposure. The wire ropes of elevators in offices, stores, warehouses, and in general buildings sometimes show an outside corrosive effect, which too often is but suggestive of the more serious hidden internal conditions. Not infrequently the interiors of wire ropes reveal disintegrated cores and corroded wires, even where there may be but little evidence of deterioration externally.

CROSS SECTION OF ROPE

The illustration herewith presented shows application of a special material, known as "wire rope filler," by which the core is lubricated and a flexible cushion interposed between it and the strands. The filler, exuding between wires, prevents abrasive wear, seals against acid, gaseous, sulphurous or water attacks, and forms foundation on which an outside coating should speedily build. Many of the prominent wire-rope manufacturers have adopted the use of this filler on all kinds and sizes of operative wire ropes. The manufacturers of this filler also make an outside coating, termed "wire rope shield," for external protection against abrasive wear, and to completely seal against exterior attacks. A substantial increase of life is evident from the internal treatment, and furthered by the external protection. The Ironsides Company, Columbus, Ohio, manufactures these materials.

International Tramways Union

The secretary of the permanent International Tramways Union, F. Nonnenberg, of Brussels, has just issued the official report of the tenth annual convention of that association, held at Geneva in August, 1898. It is also announced that the following questions will be discussed at the next convention of the union, to be held in Paris in 1900:

1. How have urban rates of fares been changed in the last five years? Why were changes made? What are the results as affecting receipts, expenses and profits? Give total figures, and figures per car mile. Do you consider your present rates reasonable?

2. What have been the consequences of electric traction upon the operation of transformed lines, as affecting traffic, expense of operating and net profits? Give total figures and figures per car mile. State nature of your electric lines as to profile, and also special circumstances influencing results, such as duration of concession, etc.

3. What are the advantages and disadvantages of narrow and

standard gages, particularly in view of the use of powerful motors?

4. What is the arrangement and equipment of your power station? (There is inclosed a list of questions covering the station, equipment and operation in great detail.)

5. What is the best system of distributing current in extensive systems using electricity—continuous, alternating, polyphase?

6. Have you used the Falk joint? For how long? On what length and what type of roadbed have you used these joints? On what technical considerations did you adopt it? What is the cost, giving items of cost in detail? What proportion of the joints break? Why do they break? Do the number of failures vary with the season? After what time do they occur? What is the maximum length of rail you have been able to cast-weld without making special expansion joints? What else can you say on this point?

7. What progress has been made concerning accumulators, as to construction, increase of capacity, decrease of weight, duration, cost of maintenance, practical and economical application on tramways?

8. Give your experience as to the best means of heating cars. Give cost of installation, operation and maintenance of the various systems you have employed.

9. What are the advantages and disadvantages of operating branch lines as compared with main lines?

No Car Vestibules in New York

The question of the advisability of compelling the street railway companies in New York City to vestibule their cars was considered at a meeting of the Board of Aldermen on Jan. 24, 1899. The proposed ordinance, which was introduced Oct. 4 by Alderman Gledhill, provided that the front platform of every car in the City of New York "operated by electricity, cable, compressed air or any other motive power except steam and horse . . . shall be vestibuled or enclosed so that no passenger shall be permitted to ride thereon, under penalty of $25, for each violation." The ordinance was referred to the committee on railroads, who held public hearings on the subject, but no advocate appeared for the measure. The committee, therefore, at the meeting Jan. 24, rendered the following report:

REPORT.

The humane purpose of the measure is fully appreciated by the members of the committee, who are in full sympathy with our vice-president, as to the necessity of devising some means to relieve gripmen, motormen, drivers, etc., from the severe hardships of storm and weather.

We feel, however, the remedy proposed is impracticable in this city, and that if applied, life and limb of pedestrians would be in jeopardy, while truckmen and others in charge of vehicles of all kinds would be in constant peril.

We have taken from the stenographer's report, and make as part hereof, the logical argument presented by one of the counsel at our hearings, to wit:

"It is really impossible to put vestibules on cars operated in the city, because, in case of a snow-storm, rain or sleet, or storm of any kind, unless the motorman drops the front glass, it is impossible for him to see more than a few feet ahead of him; and after he has gone a mile in a storm such as I have described, it would be impossible for him to see anything outside of the glass."

. . . . "It may be true that it might be tried with success in other cities, it is equally true that it would not do for traffic in the City of New York. The congested traffic in the City of New York would not allow it, in the first place. . . . Take a snowstorm like we had last week and you would find it would be absolutely impossible for a motorman to run a car even a single block with glass up in front of him. He could not run his car even at a snail's pace without striking something. You must remember that a motorman has an awful lot to do. He has got to attend to his brake. He has got to set the car in motion. He has got to start the car and stop it. He has got to listen to the bell signals. He has to look out for parties on both sides of the street. He has got to watch the track on the surface of the street in front of him. He has got to look out for small objects on the track as well as large objects, such as trucks and carriages. He has got to be alert every minute. He has got to look out for the people standing on the sidewalks wanting to get on, and he has got to listen for the conductor's bell for people wanting to get off. He has got to look out at the corner of every street for people wishing to cross the streets. He could not possibly attend to all of these things if he was enclosed in a glass case."

Another of counsel presented the following valuable opinion:

"I have heard the statement that in other cities they have tried the vestibule with success. I know they use it in Buffalo, and I have a letter in answer to one which I wrote to the manager of the Buffalo Railroad, Mr. H. H. Littell, one of the best railroad men in this country, to whom I propounded certain questions on the subject of this proposed ordinance, to wit:

" 'Do you operate vestibule cars on your road?'

"Answer—'We have about one-fifth of our cars equipped with vestibules.'

" 'Do you consider the danger of accidents to the public using the streets is increased by the use of vestibule cars in crowded cities where the climate is cold and stormy during the winter months?'

"Answer—'We find the percentage of accidents very much greater where vestibules are used than we do where they are not. They obstruct the view of the motorman when he most needs the protection afforded by the vestibule, and he is compelled to throw open the front glass in order to see. We find that during rain, sleet and soft snow it adheres to the glass and prevents him from seeing. In such cases he is forced to open the vestibule and stand in a draft which results in severe colds and sickness.'

"In other words, Mr. Littell claims that it creates a special draft, and is liable to be an injury to the motorman. He then goes on to answer the following questions:

" 'Do you think an ordinance of this character would benefit the public, irrespective of the railroad's interests?'

"Answer—'I do not see how the public could be benefited by an ordinance requiring vestibules. On the contrary, I think that vehicles and pedestrians would be subjected to a great deal more danger from vestibuled cars that obstruct the view than from open platform cars.'

"We look at this thing in exactly the same light as Mr. Littell. I am the engineer of the Nassau Electric Railroad of Brooklyn, and I know it is not a question of expense with the company that I represent in the slightest degree. Our streets in Brooklyn are narrow, as you all know; they are crowded, and they are used by a great many vehicles. We have to run our cars on a certain schedule time in order to give any rapid transit at all; and if we were to put these vestibules on our cars, I do not see how we could make time, without running the risk of a greater number of accidents than we have now. We have accidents enough now, as everybody knows, and we certainly do not want to increase the number."

The following from "The Municipal Record and Advertiser," of Feb. 26, 1898, on the subject of vestibules, sustains fully the views heretofore quoted, and has had much weight in influencing your committee to report adversely hereon, i. e.:

"The street car vestibule is, comparatively speaking, a new product in the street railway industry; as it has only been during the last four winters that it has been used to any extent. By the laws of many States the railroads are compelled to use them, and there is also a growing sentiment among managers in favor of it, even where there are no laws compelling its use. But there are also managers who will not think of adopting the vestibule unless they are finally driven to it by the courts. . . . The serious objection is the danger of running down pedestrians and running into other vehicles.

"The vestibule is simply put on the ends of the cars as a protection to the motorman, who has to face the storm, and in consequence must, in certain weather, suffer considerably; but, if he is unprotected, he is in a position to see whatever is in front of him on the street, and can manage his car accordingly. With the vestibule, at best, he can only see in front of him, and at certain angles, at the sides, as the woodwork of the vestibule shuts off his view to a great extent. In storms and snows, just when he needs the protection, he has to open the front window and stand with his face to the storm, as of old, or his view will be entirely cut off, and accidents absolutely certain to occur. If he keeps the window closed, the snow or rain will accumulate on the glass and render the operation of the car impossible. As it is, even with his face exposed, the accident possibilities are greatly increased, as the side windows are rendered nearly useless in any kind of snowstorm. Again, in very cold weather, if the windows of the vestibules are not made double, but in single panes of glass, the different temperatures of the outside and inside surfaces of the glass will cause a frosting, or thin sheet of ice, to form on the glass, through which it is impossible to see. And even if the windows are put in double, in a snowstorm where the flakes of snow are large and damp, the snow will stick to the outer glass and impair the view of the motorman.

"This one objection, on account of the greatly increased possibilities for serious accidents to the public in general, is sufficient

to condemn the use of vestibules in climates that are subject to very cold and stormy weather. The benefit is only for the few employees of the road, but the danger is for the whole public at large. This danger has been considered by railroad men to be so great that many roads have refused to equip their cars with vestibules, even though the law demands it, and they are going to let the law take what steps it may, and then fight the question out in the courts. . . ."

The importance of this subject and the desire to afford relief to the men at the front end of our cars prompted one of our members, Alderman John T. McCall, while recently at Springfield, Mass., and at Hartford, Conn., where vestibule cars are being operated, to inquire from railroad men whether they were beneficial and practicable. The responses were in the negative and the views expressed conformed absolutely to those hereinbefore quoted.

We offer the following:

Resolved, That the committee on railroads be and it is hereby discharged from further consideration of the proposed ordinances relating to vestibules on surface railroad cars, and that the said proposed ordinance be placed on file.

The recommendation of the committee was followed by the board.

Personals

MR. H. B. WESTCOTT has been appointed general manager of the Cortland & Homer Traction Company of Cortland, N. Y.

ING. S. TIVOLI has resigned from the general managership of the tramways of Alexandria and is now engaged in the commission business in that city.

MR. H. H. LITTELL, vice-president and general manager of the Buffalo Railway Company, left Feb. 26 for a two months' trip through Mexico and California.

MR. TOLNEY W. MASON, JR., has succeeded Thos. H. Gibbon as chief engineer of the Lap Joint Railway Track Company, of New York, Mr. Gibbon's term having expired Feb. 2, 1899.

MR. W. F. D. CRANE, who for seven years has been connected with the H. W. Johns Manufacturing Company, in its electrical department, has associated himself with the Electrical Vehicle Company of New York.

MR. C. G. ADNEY, formerly assistant superintendent and chief electrician of the Northeast Electric Railway Company of Kansas City, Mo., has accepted the same position with the Ogden Electric Railway of Ogden, Utah.

MR. GEO. H. PEGRAM has been appointed chief engineer of the Manhattan Railway Company of New York, and JOHN WATERHOUSE, formerly chief engineer, has been appointed consulting engineer of the system.

MR. W. C. WEAVER has retired from the management of the Northeast Electric Railway Company of Kansas City, Mo., and has accepted a position as general manager of the Ogden Electric Railway Company of Ogden, Utah.

MR. J. F. HINES has been appointed superintendent of the Winchester Avenue Railroad Company of West Haven, Conn. Mr. Hines has been connected with this road for seven years, as foreman and inspector of the city lines.

MR. WILLIAM A. GRAUTEN, formerly chief engineer of the Hartford Street Railway Company, and later of the Middletown-Goshen Traction Company, has been appointed chief engineer of the Union Railway Company of New York.

MR. HENRY H. ARCHER has accepted a position as general manager of the Belmont Tram Company of Port au Spain, Trinidad. Mr. Archer is quite well known in the United States, having been connected with the Scranton Traction Company of Scranton, Pa., and also with the J. G. Brill Company of Philadelphia.

MR. F. L. HART, general manager of the City Passenger Railway Company of Baltimore, Md., has made a splendid record for economical and effectual management. The experts who have been examining the books of this company in the interests of the syndicate that has recently purchased the property, characterize the economical showing made as "remarkable."

MR. WM. E. BAKER has been appointed general superintendent and chief electrical engineer of the Manhattan Railway system of New York. Mr. Baker for some time has been connected with the Metropolitan Elevated of Chicago, and is therefore perfectly familiar with the engineering problems arising in the application of electricity to elevated railways.

MR. H. G. FLEMING, general manager of the Little Rock Traction & Electric Company of Little Rock, Ark., has given up that position, and will be succeeded by Mr. Walter A. Badger of Boston. Mr. Fleming voluntarily resigned for business reasons, and he was presented on his departure with a letter from the directors of the company expressing their regret that he had found it necessary to leave.

LIEUT. T. C. WOOD, president of the Ball & Wood Company of New York, and who served on the "Gloucester" under Lieutenant-Commander Wainwright during the war with Spain, has been recommended for advancement eight numbers by the board of officers appointed by the Secretary of the Navy to examine into the records of the officers of the navy who made themselves conspicuous by their bravery.

MR. ALEXANDER S. GARFIELD, consulting electrical engineer with the Compagnie Francaise Thomson-Houston, arrived in the United States late in February, and will remain here from two to three months. Among other things he will inspect and pass upon the new electric locomotives for the Orleans Railroad, now building at Schenectady by the General Electric Company, and which are to be delivered by next fall.

MR. J. CLIFTON ROBINSON of London, received a very pleasant reminder of his popularity with the employees of the London United Tramways Company, of which he is managing director, upon the silver anniversary of his marriage. A committee of the tramway men waited upon him on that occasion and presented him with an elaborately engrossed address, and Mrs. Robinson with a diamond star brooch and earrings.

MESSRS. HENRY GRAFTIO, engineer of ways of communication of the Russian Government and BRONISLAS DE MINKEVITCH, railway attaché of the Russian Government at Paris, are visiting this country to investigate the subject of the electric equipment of suburban and heavy railroads. They will visit Hartford, Baltimore, Detroit and several other cities where this class of road has reached a large development, before their return to Europe.

MR. W. F. KELLY, general superintendent of the Columbus Street Railway Company of Columbus, Ohio, delivered an interesting lecture before the Department of Economics of the Ohio State University recently upon the subject of street railways. Mr. Kelly very ably compared European and American tramway practice, showing the rapid development made in America, and also gave an account of some of the operating difficulties encountered in Columbus.

MR. W. B. BROCKWAY, in recognition of his efficient services, has been promoted to the position of secretary and auditor of the Toledo, Bowling Green & Fremont Railway Company of Toledo, Ohio. Mr. Brockway was for some years assistant secretary of this company. His energetic work in connection with the Street Railway Accountants' Association of America has made Mr. Brockway very well known throughout the street railway field, and has gained for him many friends.

MR. G. PELLISSIER, the well-known French electrical engineer, arrived in New York recently from Havana, where he has been in the interests of a French syndicate, which, with the Harvey Syndicate of New York, has recently purchased the street railway system of that city. Mr. Pellissier's last visit to this country was about a year ago, when he was on a trip to New Zealand to investigate the street railway conditions in Aukland, with a view to the electrical equipment of the system in that city.

MR. W. W. CHURCHILL has been appointed to the position of mechanical engineer of Westinghouse, Church, Kerr & Co. of Pittsburgh. Mr. Churchill has been closely associated with all of the largest engineering work of Westinghouse, Church, Kerr & Co., including the Boston terminal and Third Avenue Railway power station, and well deserves the place and title which has been given him. He is a graduate of Cornell University of the class of '89, and has been with the Westinghouse Company for nine years.

DR. LOUIS DUNCAN, long well known in engineering circles as the engineer in charge of many important electric railroad installations, including the Baltimore & Ohio Tunnel electric plant in

Baltimore, and the Third Avenue Railroad in New York (on which he is now engaged), has taken into partnership Lieut. M. K. Eyre, a graduate of the Annapolis Naval Academy, and for several years past manager of the Edison Lamp Works at Harrison, N. J., which he left to join Dr. Duncan. The new firm will be conducted under the name of Duncan & Eyre, and its principal office will be in New York city.

MR. H. F. J. PORTER of the Bethlehem Iron Company, lectured to a large audience at the 521st meeting of the Boston Society of Arts on Feb. 16. His subject was "Modern Forging," and he presented in a very interesting way, with numerous illustrations by the stereopticon, the methods in vogue at the Bethlehem works of forging such articles as hollow and solid shafts, dynamo field rings, guns, armor plate. Views were shown of the hollow shafts of the "Oregon" and of the "Brooklyn," made at these works. Defects in the old methods of forging and the steps leading to the present methods were well explained.

MR. HENRY CONANT, manager of the Boston office of Westinghouse, Church, Kerr & Co., has recently received an appointment to a much higher position in that company. He will continue to reside in Boston, but his work will be of a broader nature and will be connected with the general affairs of the concern. Mr. Conant has of late been particularly well known in connection with the execution of the large engineering contract at the Boston terminal, of which he had complete charge in both management and engineering. He is a graduate of the Massachusetts Institute of Technology, of the class of '87, and by his many years of work with Westinghouse, Church, Kerr & Co. is peculiarly well fitted for the larger duties now intrusted to him.

MAJ. RUSSELL B. HARRISON, who, at the commencement of the war with Spain, went to the front with the Seventh Army Corps, is now in Camp Columbia, and is serving as provost marshal of the Seventh Army Corps for the department of the Province of Havana. Maj. Harrison, before going to Cuba, was provost marshal of the city of Savannah, Ga., while his corps was encamped there, and he was pleasantly surprised to receive from the clerk of the council of that city, a short time ago, a set of resolutions which was passed by the council expressing the high appreciation of the people of Savannah of the thoroughly efficient manner in which he discharged the delicate and important duties of provost marshal while in charge of that city.

MR. WILLIAM A. HOUSE, president and general manager of the Baltimore Consolidated Railway Company, has been one of the most conspicuous figures in the street railway history of Baltimore, and has been more intimately connected, perhaps, with the development of the Baltimore consolidated system than any other one man. He commenced his career in 1879, with the People's Passenger Railway Company, in the capacity of general utility man, his chief occupation being to collect the fares at the end of the day from the street car fare boxes. In 1883, when the People's Passenger Railway Company was reorganized, with T. Edward Hambleton as its president, the faithful services of Mr. House were recognized, and he was made secretary and general superintendent. Under his management the system, which was operated by horses, was greatly improved, and in 1889 when the Baltimore Traction Company bought the People's Railway Company and the Citizens' line, he was made general manager of the entire property. Several additional lines of the city were absorbed, and in 1892 the work of equipping the system with electricity was begun. This work was carried out entirely under Mr. House's supervision, and the present efficient and satisfactory condition of the Consolidated Railway lines is due very largely to his engineering ability and skill.

Obituary

MR. EDWIN S. CARPENTER, assistant treasurer of the Westinghouse Electric & Manufacturing Company of Pittsburgh, Pa., died very suddenly in New York on Feb. 16.

MR. A. B. JOHNSON, father of Edward H. Johnson, president of the Sprague Electric Company of New York, died on Jan. 29 from the effects of injuries received in a runaway accident at his home in Greenwich, Conn.

MR. WM. PENN COOPER, who was probably the oldest street railway superintendent in Philadelphia, died Feb. 23, at the age of seventy-six. Mr. Cooper was superintendent of the Thirteenth & Fifteenth Streets line.

MR. JOHN H. CALLAHAN, secretary of the United Traction Company of Pittsburgh, died at his residence on Feb. 13. Mr. Callahan practiced law in Pittsburgh and Chicago until about six years ago, when he accepted a position as secretary of the Second Avenue Street Railway, which position he held until the consolidation with the United Traction Company, when he was made secretary of the entire system.

AMONG THE MANUFACTURERS

THE ELECTRICITAETS-GESELLSCHAFT, Felix Singer & Co., announce that they have moved their office to Tempelhofer Ufer 10, Berlin, S. W.

THE POWER AND MINING DEPARTMENT of the General Electric Company has now under construction twelve electric locomotives for domestic use.

W. W. BIERCE has been appointed general agent for the American Rail Joint & Manufacturing Company of Cleveland, Ohio, in the Middle Southern States, with headquarters at 1106 Hennon Building, New Orleans, La.

EUGENE MUNSELL & COMPANY, of New York and Chicago, report a very gratifying demand for their India and amber "mica," of which they make a specialty for electrical insulation. Some very large orders have been received at both their Chicago and New York addresses.

THE ELECTRICAL POWER STORAGE COMPANY, LTD., of London, has found it necessary to increase the price of all its goods 10 per cent. This increase has been necessitated by the considerable advance in the price of raw materials, especially lead, during the past few months.

HOBSON & CO., of Tatamy, Pa., are sending out an illustrated catalogue of the carts, wagons, wheels, etc., which they manufacture. The list of different types includes dumping carts for every class of service, sprinkling carts, express wagons, contractors' carts and emergency wagons.

WESTINGHOUSE, CHURCH, KERR & COMPANY, of New York and Pittsburgh, received an order from the Metropolitan Street Railway Company of New York last month for the equipment of the boilers in its new Ninety-sixth Street power station with Roney mechanical stokers.

HAROLD P. BROWN, of New York, will soon place upon the market a new tie plate plastic rail bond for rebonding roads in service and for steam roads adopting electricity. The claims made for the new bond are, conductivity equal to the rail, will last as long as the rail, improves riding of track and lengthens life of rail.

THE AMERICAN ELECTRICAL WORKS, of Providence, R. I., in commemoration of Washington's birthday, sent to its friends a handsome engraving, about 7 ins. x 9 ins., of the home of Washington at Mount Vernon. This little gift will be highly appreciated by all recipients, and it is well worth a place in any office or home.

THE VAN DORN & DUTTON COMPANY, of Cleveland, Ohio, has just received an order from the Cleveland Electric Railway Company for twenty-two trucks of its latest 99 B type. The Van Dorn & Dutton Company reports that never in its experience has it been so overcrowded with work, and all departments are running to their fullest capacity.

THE LESCHEN-MACOMBER-WHYTE COMPANY, of Chicago, Ill., has been sending to its friends a very acceptable desk calendar for 1899. The calendar for each month is printed on separate cards, which are inserted in a very suitable frame made of celluloid, prettily decorated. This company reports an excellent business in railway supplies, and it is receiving orders from companies all over the country.

THE PENCOYD IRON WORKS, of Pencoyd, Pa., have received the contract for building the elevated structure of the Boston Elevated Railway in Washington Street, Boston, and Main Street, Charlestown. This is one of the most important iron contracts let for some time, and many thousand tons of metal work will be required to complete the work. The specifications require that the work shall be completed by Oct. 1, 1899.

THE CHICAGO CITY RAILWAY COMPANY, in addition to the 100 new cars now being delivered from the Stephenson Company, will soon receive fifty from the Pullman Company, and is in its own shops rebuilding thirty of its old cars. The Moore motor truck has been adopted as standard and 165 new trucks of

this type are now being erected in the company's shops. The steps on 750 open cars are being replaced by a folding step.

THE CHASE CONSTRUCTION COMPANY, of Detroit, Mich., on account of the rapid growth of its business, has been compelled to seek larger quarters, and has removed from room 1113 to suite 1321 and 1322, Majestic Building, Detroit, where it will continue its business as general contractors. This company makes a specialty of building and equipping electric railways, central stations and municipal electric lighting plants of any capacity.

THE FIRM OF Edwin C. Jones & Co., of New York, formerly the Edwin C. Jones Company, has recently been formed by the association of Peyton C. Rogers, Henry H. Pearson, Jr., and Louis H. Roberts with Edwin C. Jones. The gentlemen first mentioned have been associated for some time with Edwin C. Jones, but have not until now been financially interested in the firm. The new company will continue to make a specialty of the purchasing and selling of high-grade bonds of all kinds.

THE CAHALL SALES DEPARTMENT, of Pittsburgh, has found it necessary, owing to the very rapid increase in the price of raw materials entering into boiler construction, to advance the prices of all boilers of its manufacture 20 per cent, to take effect March 1. This action has been delayed as long as possible, as the company hoped it could go through the season without any advance, but materials have risen so rapidly in price, and continue advancing so sharply that it announces that it is obliged to take this step in order to come out even.

ELECTRIC PUMPING.—This is the title of a very attractive pamphlet just issued by the Goulds Manufacturing Company, of Boston, Mass., which describes fully the Goulds pumping machinery adapted for use with electric motors. The different types shown include direct-connected and belt-driven apparatus for a number of different pressures, varying from extremely light work to the very heaviest pressures. Street railway companies proposing to install pumping machinery at their power stations will do well to carefully investigate the apparatus manufactured by the Goulds Company.

THE C. W. HUNT COMPANY, of New York, whose work in the developing of efficient and economical hauling and hoisting machinery is well known throughout the engineering world, has published a new catalogue devoted to the description of steam and electric hauling engines. The catalogue is well illustrated, and describes a few of the many different types of Hunt hoisting engines. The hauling machinery manufactured by this company, including the "noiseless conveyor," is also shown, and will be of interest to owners of street railway power stations where it is necessary to move coal for any considerable distance from barges or railroad cars to the boiler room.

A SUCCESSFUL CAR HEATING TEST.—The Long Car Heating Company of New York city made a very successful test of its new system of hot air heating for street cars on Jan. 27, before a number of representatives of the press, including one from the STREET RAILWAY JOURNAL. The party was taken in one of the cars of the North Jersey Traction Company from Jersey City to Newark, where an elaborate luncheon was served, after which the return trip was made. The car in which the invited guests rode was equipped with the new heating system, and although the weather was damp and chilly, the interior of the car was easily kept at a most agreeable temperature.

E. F. DEWITT & CO., of Lansingburg, N. Y., received last month an excellent testimonial to the value of their boxes through the award of an order from the Third Avenue Railroad Company, for the equipment of 160 of its new cars with the common sense sand box. One hundred of these will be equipped with four boxes each and will go on cars now being built for the Third Avenue Railroad Company by the St. Louis Car Company; the other sixty cars will be made up by combining two short cars of the company's present equipment, and these will be furnished with two boxes each. The order was given after a careful investigation of the entire subject by the officials of the Third Avenue Railroad Company.

THE ALLEN & MORRISON BRAKE SHOE & MANUFACTURING COMPANY, Fisher Building, Chicago, announces to its many friends and patrons that it has gone a step higher, and has moved its office from the fifth to the sixth floor. The brake shoes turned out by this company are making some phenomenal records, some having made 30,000 miles in heavy steam road service. Some of the company's locomotive shoes have made records of 24,900 miles. The company is just now putting a new shoe on the market, which, instead of containing chilled inserts, will have the same action through the medium of deeply chilled sections of the solid shoe. This is a tire dresser, and is meeting with much favor.

IN THE ISSUE for Feb. 1, of the "United States Health Reports," a periodical published at Washington, D. C., appears an article on "Hygienic Covering for Furniture," by A. N. Tally, Jr., M. D. This article deals with the subject of the necessity for thorough cleanliness in all articles of furniture and draping used in homes, street cars and public places generally. It also draws attention to the fact that chairs and lounges, car seats, etc., are often breeding places for bacilli of various kinds, and that therefore a hard, firm, cleanly covering for seats and furniture of all kinds is extremely desirable. It further points out that Pantasote, which is a covering manufactured by the Pantasote Company of New York, very fully fulfills all the requirements of good sanitation.

THE MICA INSULATOR COMPANY, of New York and Chicago, reports very large sales, both in the United States and in Europe. This company makes a specialty of furnishing segments manufactured from micanite for any style or type of machine, and has made some segments recently as long as 30½ ins. and 4 ins. in height. Builders of electrical apparatus will do well to have before them this company's sheet, "Insulation Manual and Data Book." It not only gives the breakdown tests of its insulations, but also contains samples of micanite. A large stock of micanite plates, cloth, tapes, paper and "Empire" and "M. I. C. compound" insulation is carried at New York and Chicago; also at the company's agencies in Cincinnati, St. Louis, San Francisco and Cleveland.

THE WESTINGHOUSE MACHINE COMPANY, of Pittsburgh, Pa., is sending out another of its very readable catalogues, this one being devoted to the Westinghouse standard engine. This type of engine is designed for those locations where the use of a simple non-condensing engine is consistent with the principles of good engineering and commercial economy, the conditions under which it is particularly economical being, of course, wherever there is a good demand for exhaust steam. Although its field is somewhat limited, yet the manufacturers state that the demand for this type is constantly increasing, and the company believes that with variable loads and light loads the Westinghouse standard is superior to the usual type of four-valve simple non-condensing engines.

THE GARTON-DANIELS ELECTRIC COMPANY, of Keokuk, Ia., has recently appointed Mayer & Englund, of 10 South Tenth Street, Philadelphia, its representatives in the Middle States territory for its line of railway lightning arresters. The Garton-Daniels catalogue for 1899, just issued, is unusually complete, and should be in the hands of every one using lightning arresters. The catalogue clearly describes the requirements of lightning arresters for all classes of service, and gives data regarding the different types of Garton arresters, and shows how these instruments have been designed to fully meet the difficulties encountered in practical operation. The last few pages are devoted to letters from customers, testifying to the perfect satisfaction given by the Garton instruments.

THE INTERNATIONAL AIR POWER COMPANY, which was organized in January with a capital of $7,000,000, as stated last month, has increased its capitalization to $8,000,000, and of this amount $600,000 is in preferred stock. This preferred stock has all been taken up and was largely oversubscribed. It is understood that the common stock will shortly be issued and placed upon the market. In addition to the works of the American Wheelock Engine Company, and the Rhode Island Locomotive Works in Providence, the company has recently purchased another large engine works. Among those interested in the International Air Power Company are Joseph Leiter of Chicago, P. A. B. Widener, George W. Elkins and Thomas Dolan of Philadelphia and J. H. Hoadley of New York.

THE ANNUAL MEETING of the Newburyport Car Manufacturing Company of Newburyport, Mass., was held Feb. 20, 1899, at the office of the company and the following officers were elected: President, E. P. Shaw; treasurer, W. F. Runnells; directors, E. P. Shaw, L. Marquand, L. W. Sargent, W. F. Runnells, all of Newburyport, and Chas. A. Haines of Melrose, Mass. The company has rebuilt its factory, which was destroyed by fire last April, and has now a complete modern plant with the latest labor saving machinery and starts once more with good prospects and several large orders. J. W. Evans, the general manager, who has been ill, is much improved and again takes an active part in

the affairs of the company. The showing made last year, considering the delay occasioned by the fire and consequent loss of orders was satisfactory and the outlook for the future promising.

THE WESTERN ELECTRICAL SUPPLY COMPANY, of St. Louis, Mo., has added some very satisfactory agencies to its street railway department, and makes the announcement that it has secured the Southwestern selling agency for the Star Brass Works of Kalamazoo, Mich., for the well-known "Kalamazoo" self oiling trolley wheel, also for the Van Dorn & Dutton Company of Cleveland, Ohio, for its gears and pinions, that have been meeting with success among the street railways throughout the country. The Western Electrical Supply Company has also secured the agency for the Sterling Varnish Company of Pittsburgh, Pa., for its well-known varnish and insulating compound. With the above agencies added to its already very complete assortment of street railway supplies, the Western Electrical Supply Company believes it can handle any street railway orders to the entire satisfaction of its customers.

THE J. G. BRILL COMPANY, of Philadelphia, has received some very interesting testimonials to the value of its metal seat-end panel. One of these is from the Mobile Light & Railway Company, the manager of which writes that about four years ago he purchased some second-hand cars of the Brill make, equipped with these panels. These cars had been in use by another company for ten or twelve years, yet they are still in good condition, while two other cars at Mobile, made by another car builder, have gone to pieces within three years, largely for the want of these malleable end seat panels. The Brill Company is also in receipt of a letter from the Chattanooga Electric Railway Company, referring to the Brill 21 E truck as the smoothest riding truck on the market, and another from a railroad official of Bristol, England, referring to a parlor car built by the Brill Company for the railway in most favorable terms.

VALUABLE COLLECTION OF RAIL SECTIONS.—The American Rail Joint & Manufacturing Company, of Cleveland, Ohio, has published its new catalogue describing the American rail joint, which is well known to street railway managers in the United States. An extremely valuable feature of this catalogue, and one which will be appreciated by street railway managers, is a collection of rail sections, which includes the shapes, makers' names and weight of every rail section manufactured by all the well-known rail manufacturing concerns in the United States, with the exception of one. The cuts are all one-fourth size, and the method of adapting the American rail joint to each section is shown. As this is probably the first time that such a complete collection of rail sections has been published in so convenient a form, the American Rail Joint & Manufacturing Company is certainly to be congratulated upon its enterprise in undertaking the work. Copies of the catalogue will be mailed by the publishers on request.

WARREN WEBSTER & COMPANY, of Camden, N. J., report the following plants in which the Webster system of steam heating has been installed: Creedmore Mining Company, Creede, Colo.; Ohio State Capital Annex, Columbus, Ohio; Washington County Court House, Washington, Pa.; Steel Pier, Atlantic City, N. J.; St. George's Hotel, Evansville, Ind.; Pennsylvania Railroad Ferry, Jersey City Terminal, N. J.; J. G. Brill Company, Philadelphia, Pa.; Pennsylvania Institute for In. of Blind, Overbrook, Pa.; Toronto Carpet Company, Toronto, Canada; Fraser & Chalmers, Chicago, Ill.; Elgin National Watch Company, Elgin, Ill.; Reliance Building, St. Louis, Mo.; Dental Snuff Mill, Lynchburg, Va.; West End Trust & Safe Deposit Company, Philadelphia, Pa.; Penobscot Chemical Fibre Company, Great Works, Maine; Consolidated Fruit Jar Company, New Brunswick, N. J.; St. Louis Club, St. Louis, Mo.; Indiana State University, Bloomington, Ind.; New York, New Haven & Hartford Railroad Company's depot, Providence, R. I., and many others.

THE JOSEPH DIXON CRUCIBLE COMPANY, of Jersey City, N. J., has received the following letter from C. D. Shepard, superintendent of the Palmer & Munson Street Railway Company, to whom the credit for this new use for graphite is due: "A lubricant of some sort must be used on the cylinders of controllers on all electric cars. Every electrician having charge of electric cars knows, or has experienced, the trouble pertaining to the use of any kind of grease or oil, by dust sticking to the cylinder contacts, thereby cutting the cylinder and making poor contact, which causes the controllers to arc, thus destroying the life of the cylinder and fingers, also making it necessary to look over the controllers at least once a week, and sometimes oftener. By the use of Dixon's No. 635 graphite this trouble can be remedied. Pure graphite being of high conductivity, and at the same time the best solid lubricant known, it has been demonstrated by practical experience that it is the only lubricant which dust will not stick to, and which will not interfere as a lubricant with making a sure contact between cylinder and fingers, giving a smooth surface on cylinder, allowing controller to be turned easily and smoothly, requiring attention only once a month."

A VERY HANDSOME PORTFOLIO.—An extremely handsome and novel portfolio is being sent out by the Crouse-Hinds Electric Company of Syracuse, N. Y., manufacturers of the Syracuse changeable electric headlight. It is made of heavy green paper and is richly embossed on the outside. Contained in the portfolio are some twenty-nine letters from street railway companies indorsing the Syracuse headlight and testifying to its good qualities, but instead of printing these indorsements in the ordinary way, the Crouse-Hinds Company has had each letter reproduced in its entirety and printed upon the same kind of paper as the originals were written upon. This has been done at a very considerable expense, and the results are very pleasing and must certainly prove very effectual. The testimonials are unusually strong and, in a number of cases, in addition to expressing satisfaction, contain orders for more headlights. The portfolio will be sent on request. The Crouse-Hinds Company reports that its factory, which was lately enlarged to twice its previous size, is already overflowing with orders. The fact that the Syracuse headlight can be changed in a moment from one end of a car to the other, or from a winter car to a summer car, thus practically doing the service of four ordinary lights, makes it extremely popular.

New Publications

The Register of Lehigh University, South Bethlehem, Pa., for year 1898-99. Paper. 220 pages. Published by Lehigh University, South Bethlehem, Pa.

The Register contains the usual announcements for the coming collegiate year, a full description of all the courses and a full list of all students at the college and also of the alumni.

Fowler's Mechanical Engineer Pocket Book, Edition of 1899. Edited by William H. Fowler. Leather. 324 pages. Illustrated. Price 1s. 8d. post free. Published by Scientific Publishing Company, Manchester, Eng.

This is one of the most reliable and valuable of the engineers' pocket books published, and contains an immense amount of well digested and carefully indexed material of use to engineers.

Map Showing Street Railway Lines in Massachusetts, Rhode Island and Connecticut. Published by Robert H. Derrah of the Boston Elevated Railway Company, Boston, Mass. Mounted on cloth. Price $15.

This map is printed in four colors and shows all existing and projected street railways in Massachusetts, Rhode Island and Connecticut, as well as the steam roads. The map is drawn to a scale of four miles to the inch. To one not familiar with the situation, a glance at this map will be most surprising, as there is hardly a corner of this territory that is not already occupied by street railway lines. According to this authority, it will soon be possible to travel from Boston or points fifty or seventy-five miles east or south of Boston by electric cars, via South Framingham, Worcester, Springfield, Mass., Hartford, New Haven and Stamford, Conn. The map will be of great value to anyone interested in the development of electric railways.

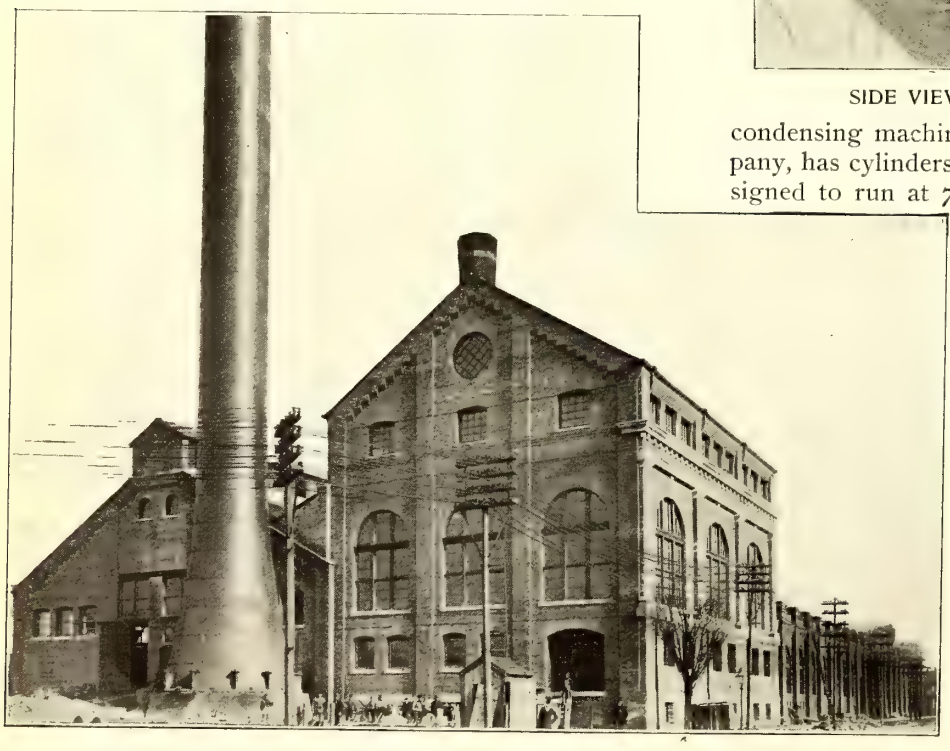
VOL. XV. NEW YORK AND CHICAGO, APRIL, 1899. No. 4.

POWER STATION AND REPAIR SHOPS OF THE CLEVELAND ELECTRIC RAILWAY COMPANY

There are very few stations in this country where it is possible to find in operation equipments that illustrate in distinct stages the evolution that electric railway power houses have undergone since the introduction of this new power for transit purposes. Such a condition exists, however, in the station of the Cleveland Electric Railway Company, generally known as the "big consolidated" company. The principal interest in the station centers in the new engine and generator, illustrated on this page. This machine stands 32 ft. high above the floor line, and is artistically designed, all the curves being graceful, while strength is not sacrificed. The engine is direct coupled to a 2400-

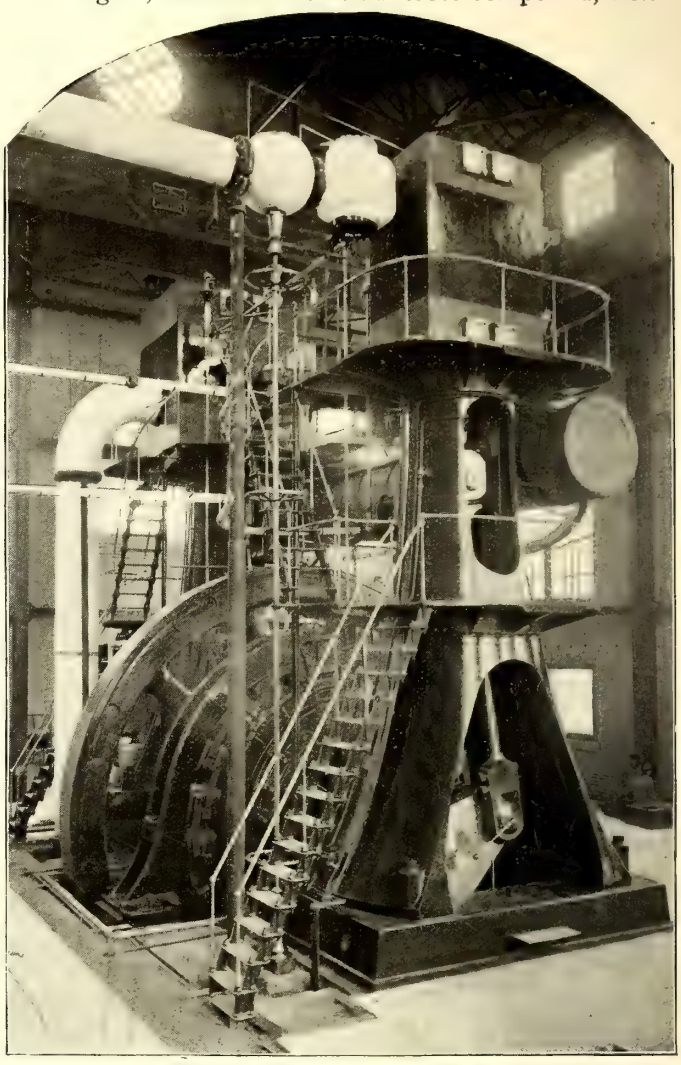


VERTICAL COMPOUND ENGINE AND 2400 KW. GENERATOR IN CLEVELAND ELECTRIC RAILWAY STATION

kw. twenty-two pole, railway generator, the armature of which is 12 ft. in diameter and 2 ft. across the face.

The generator is of the General Electric make, wound for 550 volts and 4300 amps. The magnet frame is of cast steel of highest permeability, and is heavily ribbed, to give great mechanical stiffness. It is provided with feet of large area, in order that the machine will rest firmly on the foundations. The pole pieces are of laminated sheet iron, and are rectangular in cross section. The poles are so shaped that the eddy current losses are reduced to a minimum. The spools are composed of heavy brass flanges, the body of the spool being of two thicknesses of sheet iron. The spools are thoroughly insulated by means of veneer board flanges, oiled cotton and mica. The series winding consists of copper strip, and the shunt winding of triple cotton-covered wire.

The armature spider is of such construction that all shrinkage strains are obviated. The spider is made in halves, in order to facilitate assembling on the engine shaft. The spider arms are hollow, to give the greatest strength with the given amount of material. The laminations are thoroughly insulated from one another by means of japan. The slot insulation consists of alternate layers of oiled muslin, paper and mica. The armature bars are of such a shape that the only joints occur at the commutator leads. That is, the bars have no joint at the flywheel end. The armature bars are held in position by means of wooden wedges, thus doing away with binding wire over the laminations.



The commutator shell is supported on an extension of the armature spider, to avoid any possibility of movement between the commutator spider and the armature spider. The bars are hard-drawn copper, insulated from one another and from the spider with the best grades of selected mica. The commutator is of such a size that a large number of brushes can be used. This gives low current density in the brush with attendant low heating. The brushes are supported by means of a heavy cast-iron yoke, which is operated by suitable worm gearing.

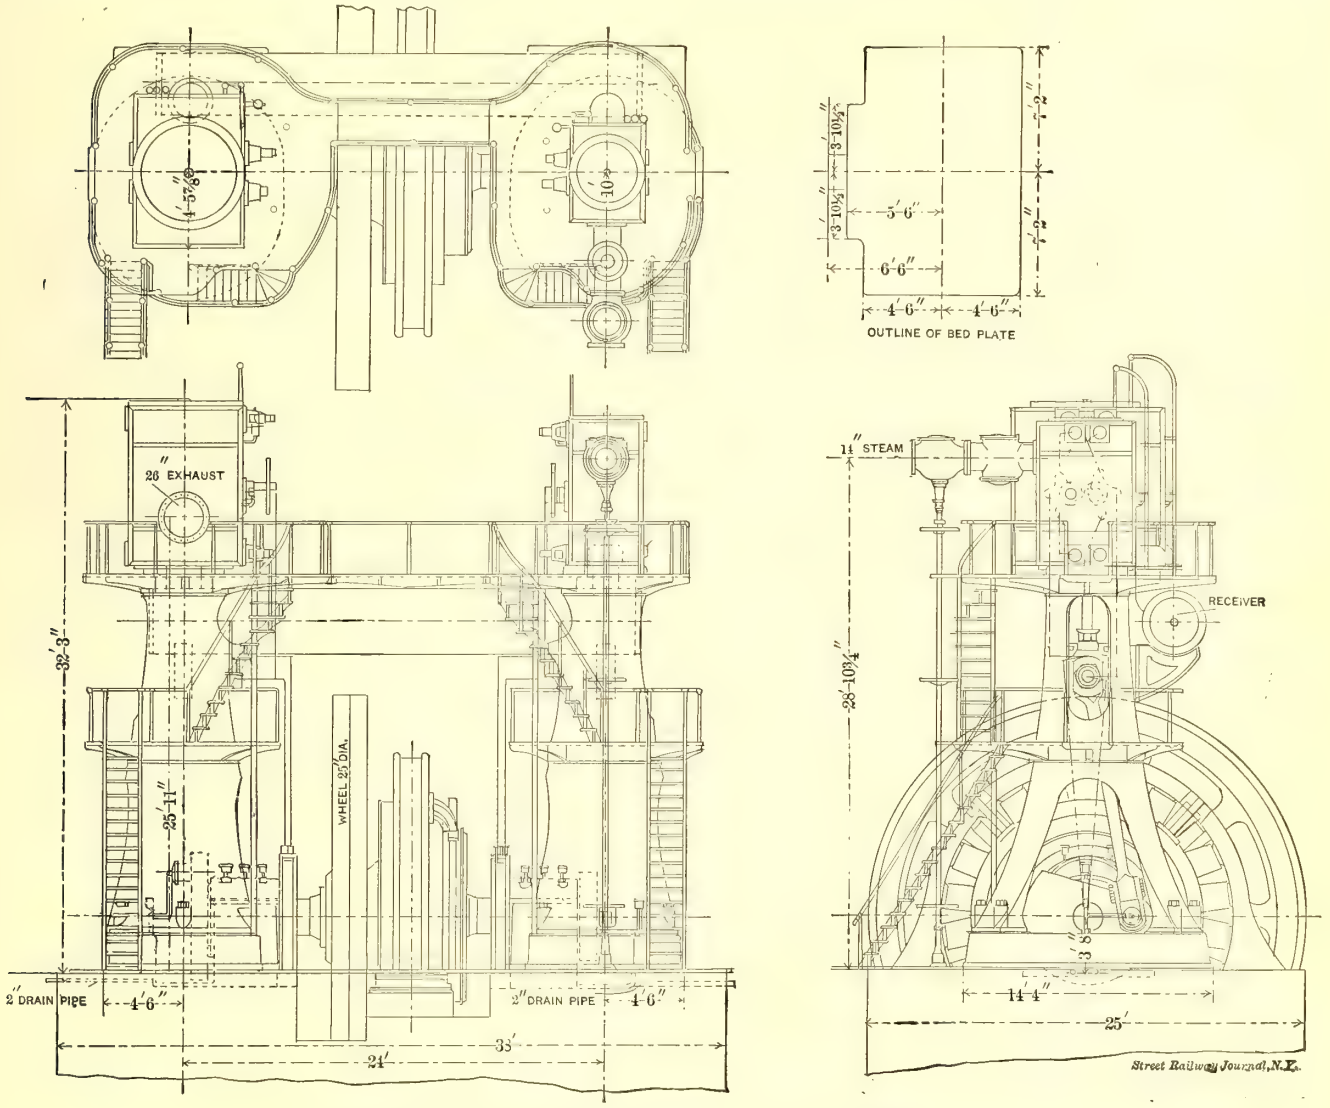
EXTERIOR OF POWER STATION

The main dimensions of the generator only are: width, 270 ins.; length along shaft, 61 ins.; diameter of shaft, 27 ins.; total weight, 180,000 lbs.

The engine, which is a vertical cross-compound, non-condensing machine, was made by the E. P. Allis Company, has cylinders 40 ins. and 68 ins. x 60 ins., and is designed to run at 75 r.p.m. with 160 lbs. initial pressure. The valves are in the cylinder heads, and a separate governor is used for operating an automatic safety stop. The main throttle valve is operated from the different platforms by means of hand wheels attached to a vertical shaft, and each cylinder is approached by steps, as shown in the illustration. The flywheel is 25 ft. in diameter and weighs 160,000 lbs. The shaft is 25 ft. long, and at the center where it carries the armature it is 26 ins. in diameter, but reduced to 24 ins. at the bearings. The bearings are 48 ins. long, and made with shells supported by ball-joint bearings, thus insuring perfect alignment.

SIDE VIEW OF ENGINE AND GENERATOR

While the engine is rated at 3500 h.p., it is capable of being worked up to nearly 5000 h.p. for short periods. The engine room is supplied with a 30-ton electric traveling crane having three motors of the railway type. This crane is carefully designed in every detail, even the forged hook of the hoist being hung in ball bearings, so that it swivels easily. The crane was designed and manufactured



by the Brown Hoisting & Conveying Machine Company, of Cleveland.

The auxiliary steam equipment consists of duplicate pumps of the Worthington manufacture, and is located in the engine room. The valves are all of Chapman manufacture. There is a complete automatic oiling system and other detailed features that embrace the very latest in power house design.

The boiler room adjoins the engine room, and both are extensions of the old plant, but at a higher level. The new boiler equipment consists of ten water-tube boilers of the B. & W. type, each rated at 264 h.p. at 30 lbs. evaporation. These boilers are arranged in batteries on each side of the boiler room floor, there being six on one side and four on the other. These are each equipped with the B. & W. type of chain grates, which are operated from a horizontal shaft above the boilers, and which in turn is actuated by special engines.

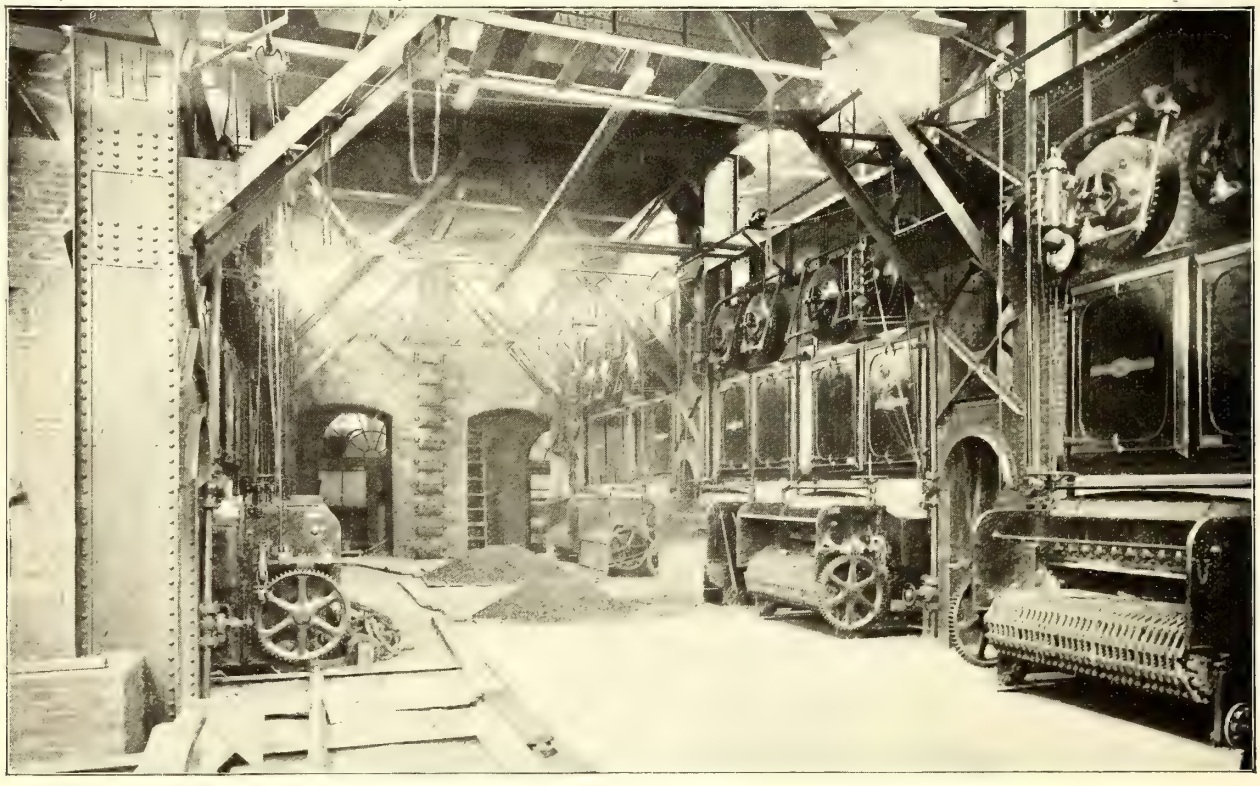
The steam piping is all of lap-welded type, and is bent in suitable curves in order to avoid as much as possible fittings, and at the same time provide for expansion. The boilers are connected by 8-in. pipes, which lead directly into a 20-in. steam header. Those from the boilers on the off side of the room pass over the area between the boilers and just below the coal bunker, when, coming alongside of the pipes from the other boilers, they bend in pairs on the same curves and are attached to the top of the steam header. The connection is made through a specially designed T, having two openings on top, in which the stop valves to the boilers are placed. The main header is supported on a steel platform built out from the walls of the station just above the back of the boiler. This is guarded by a railing, and the header, except at the center, is supported on small steel trucks, which are designed to move back and forth to accommodate expansion and contraction. In order to prevent these trucks from vibrating the weight is supported on small journals, while the surface of the rollers, which are about 3 ins. in diameter, rests on a plate, so that because of the different diameters a sort of breaking power is obtained. A 15-in. curved pipe leads out from the top of the header, and, passing through the wall, leads directly to the throttle of the high-pressure engine.

Drain pipes are attached to the valves and lead across into the bends of the steam pipes to provide for automatic drainage. From the bottom of the steam header short loops connect with a drip header, which is located beneath the main header, and from this the drip is returned to the end of the boiler with the use of any special appliances. The sections of pipe are provided with weldless soft steel flanges manufactured by the Latrobe Steel Company. These are faced and beveled to a slight taper, the greatest diameter being at the face where the pipe is flanged and peaned into a groove in the face of the flange. The pipe is then faced off so that it affords a smooth seat for the gaskets, so that the greatest pressure comes directly on the end of the pipe, all pipes from 8 ins. and upward being peaned in this manner. The feed water pipes are attached

SIDE AND END ELEVATIONS AND PLAN OF ENGINE

to the front of the boilers above the stoker in a peculiar manner, as shown, and provide for expansion, the pipes being bent to 90 degs. and a 1½-in. pipe leads down to an automatic stop check valve. The main header is ⅜ in. in thickness, and all the pipes are of standard weight, except those for feed water and blow off, which are extra heavy, to provide for corrosion.

The exhaust pipe from the low pressure side leads down and bends beneath the floor and enters the feed water heater, which is of the Goubert type.



The steam pipe leading to the pumps is provided with a check valve which automatically regulates their action. This is known as the Foster valve, and avoids the use of the ordinary type of regulating valves.

The exhaust from the high pressure cylinder is led into a cylindrical connecting chamber about 4 ft. in diameter, from which it is directed to the low pressure cylinder. This chamber, as well as all the steam piping, is thoroughly covered with magnesia heat insulation material, manufactured by the Keasby & Mattison Company, of New York, but installed by the Cleveland branch of that company.

The coal handling equipment is very complete, and consists of a steel bunker located above the boiler room, having a capacity of 11 tons to the linear foot, or a total storage capacity of about 900 tons of coal. From the bunker coal is delivered to the chain grates by chutes. The bunker is lined with brick to prevent wear. Coal is received direct from the steam railways in bottom hopper cars, and dropped into a receiving bin underneath the track, which is also brick lined, whence it is conveyed by means of a trough belt conveyer part way across the station, when it is transferred to a bucket conveyer running underneath the boiler room floor, and making the circuit along the sides and above the coal bunker. The belt conveyer is of the Robbins Company's manufacture, and the bucket conveyer of the C. W. Hunt type. Cast iron is employed for these buckets, because it is less liable to rust than rolled steel. Both are driven by independent electric motors. The bucket conveyer serves for handling the ashes as well as the coal, and these are delivered into an elevated hopper placed at one end of the room in line with the boilers, and of sufficient height to allow of trolley construction cars being run under the spout, so that the ashes are loaded direct without any shoveling. These ashes are employed along the line of the road as ballast.

The extension of the building for the accommodation of the additional equipment above described is of brick, and quite artistic in design. The engine room has a ground dimension of 55 ft. x 82 ft.; the walls are 58 ft. to the eaves, and the roof is supported by steel trusses having curved lower chords. The boiler room is 85 ft. wide, and of the same length as the engine room, but is not as high, although there is a peculiar combination of the steel structural work in both departments, as it was necessary to carry the wind strains of the engine house through to the boiler house in order to get to the ground.

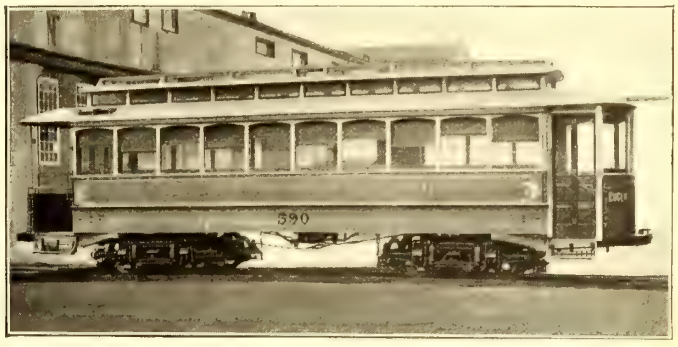
Two flues lead out from the boilers under the floor and communicate with the smoke stack, which is located against the end of the building. This is self-supporting, brick-lined and of steel. The base is bell shape, 25 ft. in diameter, and thoroughly anchored to the foundations, as shown in the illustration. The trunk of the stack is 13 ft. in diameter, and the flue is 10 ft. 6 ins. inside diameter. The total height above the base is 225 ft.

INTERIOR OF BOILER ROOM

An interesting feature should be noted in connection with this new equipment to account for the engine being run non-condensing. It is proposed to employ the exhaust steam in the evaporating appliances of a neighboring salt plant, which is located about 800 ft. from the power station, The steam will be carried in an underground conduit, suitably insulated, and delivered as above noted to the salt works under an agreement from the salt manufacturing company to pay one-half the cost of fuel required to run the station. In this connection it is interesting to note that these works have recently drilled three wells, 2000 ft. in depth, where is found a bed of salt which underlies, it is supposed, the whole city. The process of mining con-

sists in forcing a stream of water down one of the tubes of the well. This dissolves the salt, which is then forced out through another pipe. The salt is then extracted by an evaporating process.

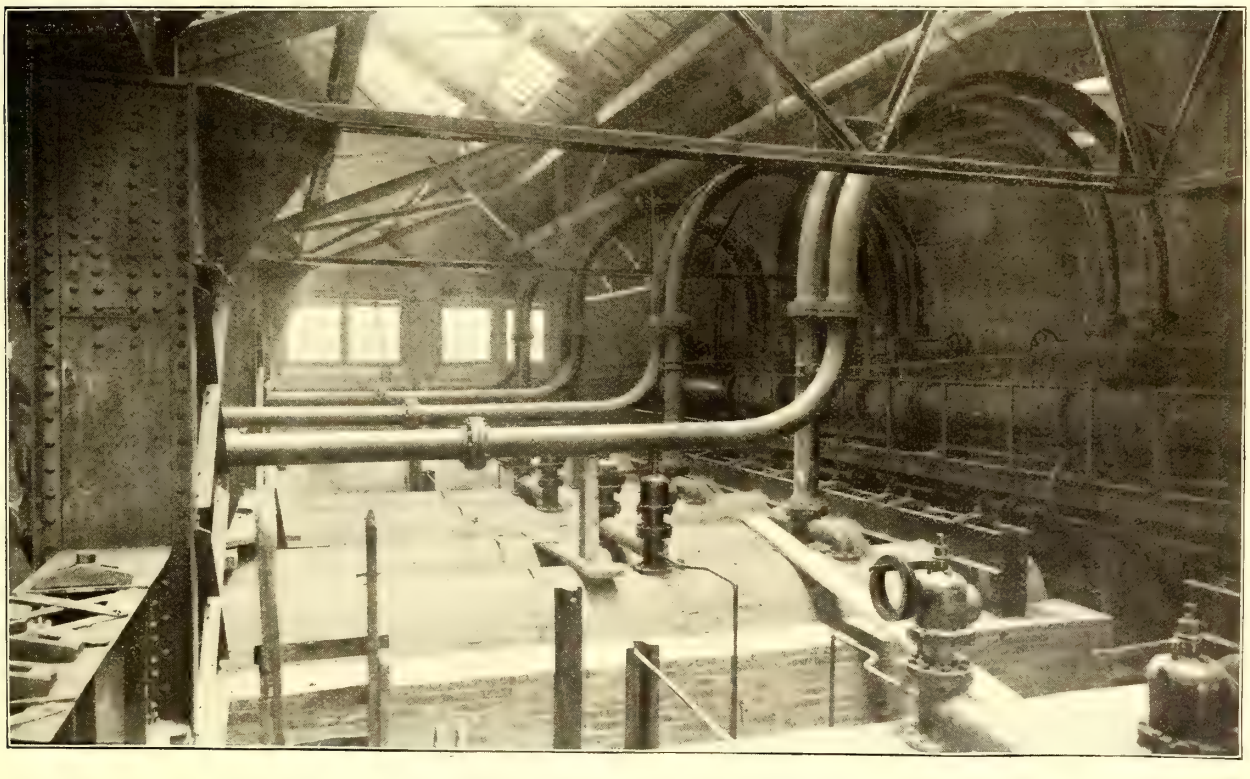
The first power equipment consisted of two high-speed 125-h.p. Armington & Sims engines, each belted to a No. 32 Edison generator. The next installation consisted of three 225-h.p. engines of the same make, each belted to two No. 32 Edison bipolar generators. The third installation introduced the jack shaft, and this was driven by three Cooper Corliss engines, each having cylinders 28 ins. x 48 ins., one being attached by belt to each end of the shaft, and the second to an intermediate pulley. From this shaft, by means of belts, seven No. 60 Edison generators are driven. The fourth step included the installation of four Cooper Corliss engines, each belted direct to a 500-kw. multipolar G. E. generator. A fifth installation consisted of an E. P. Allis Corliss engine, which drives by means of two belts from the flywheel two No. 60 Edison generators. The sixth and latest installation is the direct-coupled unit described above. All of these equipments are now in use, except the first.



The boilers of the original plant are horizontal return tubular, but are equipped with Murphy stokers. The entire output of the old station is 6500 amps. at 550 volts. There is also a supplementary station on Canal Street of 2200 amps. capacity, consisting of Ball engines and old D 62 T. H. generators, which are still in service.

The current from the new equipment is directed to a temporary switchboard near the middle of the old station, the principal features of which are an automatic circuit breaker of the capacity of 6000 amps., which is of the G. E. manufacture, and the new static meters of the same make.

The new plant was designed by E. J. Cook, the company's electrical engineer.

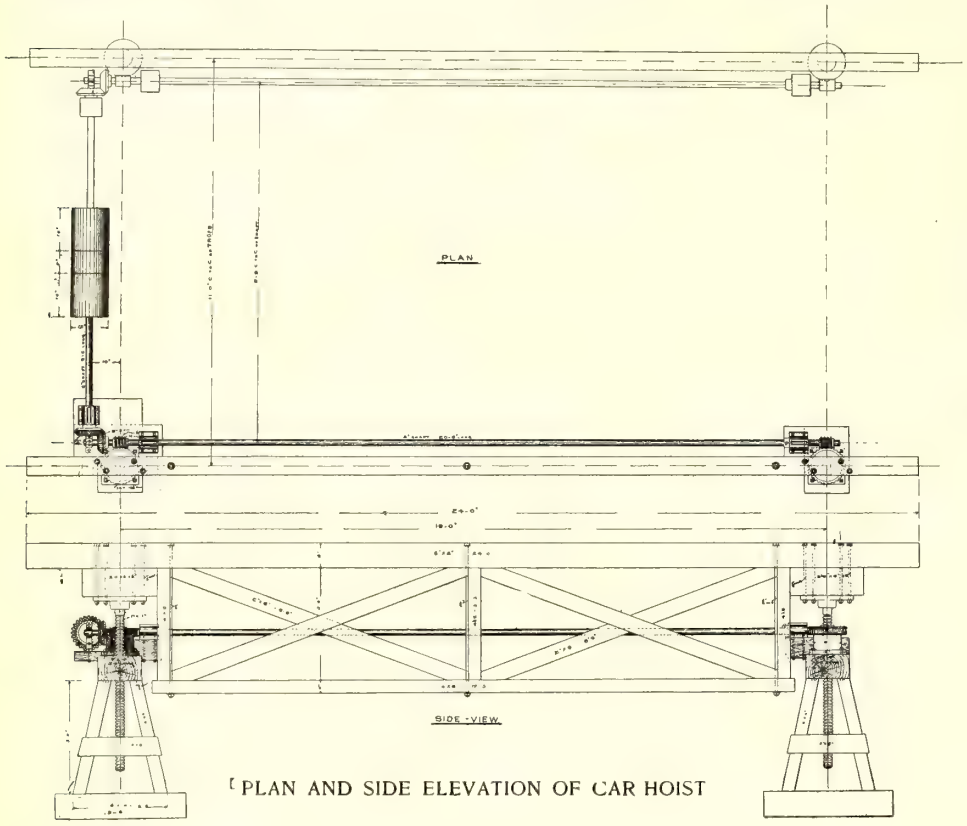


REPAIR SHOP.

The principal repair shop of the system is located at Lakeview, well on the outskirts of the city. All the repair work for the system is done here, and the large cars of two of the suburban railways of Cleveland are also brought to these shops for painting. Just at present part of the work at these shops consists in changing one of the eight-wheel high-speed cars and making it over for use as a

STANDARD CAR

funeral car. One compartment of the car is being furnished with four drop doors on the side, through which the caskets are to be loaded. The floor of the car is fitted with sunken rollers to facilitate handling of the caskets. The second compartment is designed for carrying the friends and attendants, and it is intended to run in connection with this car special funeral trains. The car is suitably designed and decorated, the exterior being black with gold trimmings. The expense of refitting this car is to be borne jointly by the two principal companies controlling the city lines, and the car is designed to run to all the principal cemeteries, of which, at present, there are six. These cars are to have the right of way, and suitable switches are being put in near the entrance gates of the cemeteries. New signs have recently been designed, which are to be carried by such cars as pass the different cemeteries.



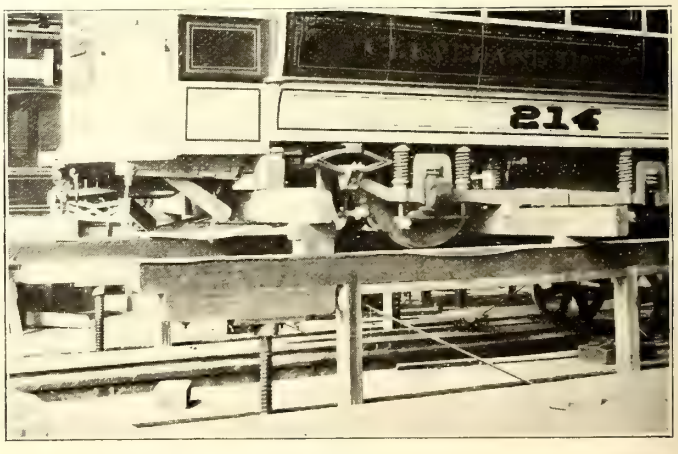
VIEW OVER BOILERS SHOWING PIPING

The company is also rebuilding a number of its six-bench open cars and making them into eight and ten-bench cars. The sills and floors will be entirely new, and

the end posts, while the old intermediate posts and the seats are retained.

The company has recently ordered 100 new eight-wheel cars. Fifty of them are to be fourteen-bench open cars, 34 ft. in length, and the others closed cars with side seats. The closed cars are to be 28 ft. over all. Six of these cars have already been built, five of them being from the John Stephenson Company and one from the J. G. Brill Works.

PLAN AND SIDE ELEVATION OF CAR HOIST



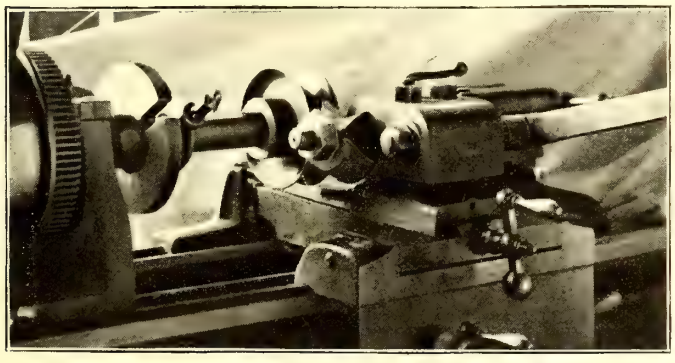
Five cars are mounted on Brill trucks and one on Peckham trucks. These cars are modeled after those employed on the Metropolitan Street Railway Company's lines in New York, and are all painted canary yellow. This is to be the standard color for all cars on the Cleveland electric system, and the present equipment is being repainted as fast as it comes into the shop. A number of box motor cars are being fitted up and equipped with two No. 49 Westinghouse motors, which will haul trailers and will be used for picnic parties, but it is the intention of the company to replace all its trains with long cars, so that within a year it is expected that the practice of running trailers will be discontinued, and the present side-door cars will also be replaced with long cars. A dozen new trucks, designed by the master mechanic and manufactured in Cleveland, but known as the Dorner truck, have recently been substituted for another truck formerly employed under the side-door cars.

The company has also recently ordered 200 new motors of the No. 49 Westinghouse type, which will replace a number of the motors now running. A number of Westinghouse No. 12 motors that formerly had center suspension have been made over in the shop for nose suspension. These motor cases have also been equipped with new armature bearings, or rather, blocks for supporting the bearings. It is now the practice of the master mechanic to cast his motor bearings, solid or cylindrical, of babbitt metal and use them without shells. When worn, the bearings are recast, and at each remelting a letter is stamped in the end of each bearing which indicates how many times the metal has been recast. After it becomes too hard for use as armature bearings, it is employed for the axle bearings, and when all the wear is out of it the metal is scrapped.

Illuminated signs are carried on all cars, one on the hood, which indicates the principal street or avenue on which the car runs, the other on the dash, which indicates the terminal point. In the closed cars the socket for the illuminated sign is on the end of the dashboard, while on the open cars it is in the middle.

Four dismantling devices are employed in the motor repair department of the shops. Each of these consists of a timber bent or truss of the same length as the car, and one is placed on each side of the repair pits. When not in use the top of these trusses comes flush with the floor, but they are designed to be elevated by means of screws, which are placed one under each end of each truss. These screws are connected together with beveled and worm gear, and are driven by an electric railway motor, so that the two trusses are lifted at the same time. By placing timbers from one to the other under the car body the car is readily lifted and held firmly in position, when the axles and motors are readily run out and a new set substituted, while necessary repairs are being made. Two of these dismantling appliances are placed near together along the same pit, so that one motor operates two. By means of a friction gear either set is operated.

Another convenient device employed in this department is an armature shifting truck, which consists of a pair of small wheels with long handles, which terminate on one side of the truck in curved hooks, the whole being so designed that the hooks may be placed under the ends of the armature shaft, when, by pressing down on the handle, the armature is lifted and can be readily rolled to any position. The repair pits are also equipped with a portable hydraulic armature removing device, which has previously been illustrated in these columns.



SIDE VIEW OF CAR HOIST

In the winding department only six men are employed for all the repair work, with the exception of the commutator repairs. These are refilled and new ones pur-

chased from some one of the armature repair companies and commutator builders in the city. All armature repair work is done by the piece, the price being fixed for every part of the armature. Coils are made and taped, and all other work done as indicated above. Piece work is found to be more satisfactory both to the company and to the employees, as each man is held responsible for his job, and if it is not satisfactory is required to do it over. A large galvanized iron oven with folding top is used for baking the armatures and coils. The heat is generated by means of a number of electric heaters of the Consolidated Company's type. Self-heating soldering irons are also employed; in these a stream of gas and compressed air is delivered to the head through suitable flexible pipes, so that no time is lost in waiting for an iron to heat.

The warehouse and storeroom to which all material is delivered is located on the second floor of the building, and is served by an elevator, by means of which the material is received and delivered. All material is dealt out on an order, which is made out by the man in charge of a piece of work. All orders are then countersigned by one of the foremen, so that not even a screw can be gotten from the storeroom without a proper order. By this means a careful record of all material is kept, and it is charged up to particular jobs. Cars are shifted between the paint shop and the other departments by means of an electric transfer table, which operates in a sunken way and takes its current from a third rail. This table is to be enlarged, and to make room for it the side wall of the paint shop is to be set back.

The iron-working department is equipped with a good complement of iron-working tools, to which has recently been added a wheel-boring mill, made by Henry Bickford, Lake Port, N. H., but was purchased from the W. H. Patterson Supply Company of Cleveland, Ohio. Among the labor saving devices in the shop is noted a turning head for turning out the groove of trolley wheels, which is automatic in action, and when set on one flange bores

LATHE FOR TURNING TROLLEY WHEELS

down the side and around the groove and up the other side without attention, so that all wheels are turned to an exact diameter.

The shop tools are operated by a 75-h.p. electric motor, which is located in one corner of the room and housed in for protection. It is the practice in the shops to prepare and press on all wheels, and for this purpose there are a hydraulic press and other suitable appliances. In connection with the repair department should be noted a wheel grinder of the Murphy type.

The affairs of the Cleveland Electric Railway Company are now under the direction of Henry Everett, president and general manager. Mr. Everett is also interested in a number of cross country lines which reach out from Cleveland, and in which department of street railroading Cleveland has until recently taken the lead.

Cast Welding Joints in New York

When the Third Avenue Railroad Company decided to change over its horse and cable lines to conduit electric construction the most careful consideration and thought were given to the subject of joints; in fact, this company's experience with joints on its cable construction had been so unsatisfactory that more attention was given to this point, perhaps, than to any other one feature. The cable track was laid in 1893 in accordance with the best engineering practice known at that time. It consisted of 7-in. 80-lb. rail laid on the concrete structure of the conduit. The rail rested upon cast-iron yokes spaced 5 ft. apart, but between these supports the concrete was packed tight under the base of the rail. The splice bars were 30 ins. in

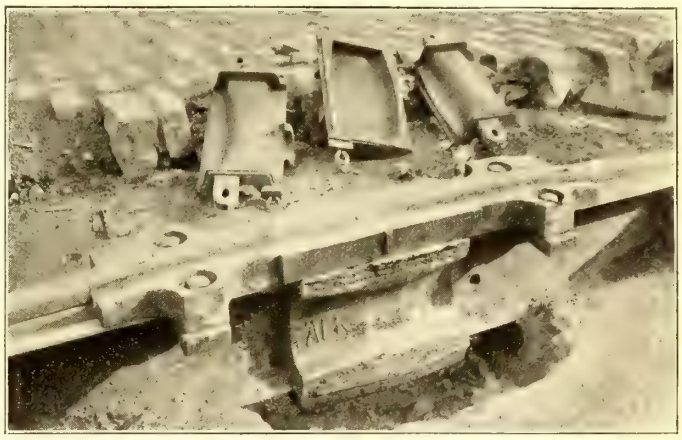


FIG. 1.—BRIDGE FOR COVERING JOINT

length and connected through the web with six $\frac{3}{4}$-in. bolts. The joints were suspended and broken. Owing, however, to the enormous traffic passing over these cable lines, this construction has not proven effectual. The joints have gone down $\frac{3}{8}$ in. in some places, and the rail itself has become badly worn, not only on the head and tram, but also underneath both, owing to the action of the splice bars. Some of the curious results of this heavy traffic on the joints and rails were described in the STREET RAILWAY JOURNAL for July, 1898

In view of this experience, and also taking into consideration that the traffic on the new electric construction will undoubtedly be heavier than it was on the cable lines, it can be seen that the problem of properly supporting the rails and joints in the new work was a most serious one. The type of conduit construction finally decided upon was shown and described in the STREET RAILWAY JOURNAL for December, 1898, and it was also there stated that the company would cast weld a large number of the joints according to the Falk system. The contract for part of this work was made some time ago, and the Falk Company has been at work for several months cast welding joints on the Amsterdam Avenue line, and also on the main line on Third Avenue. The first order was for welding over 10,000 joints, or about 65 miles of track.

In order to meet the peculiar conditions existing in New York, the Falk Company made a number of important changes and improvements in its method, a description of which will be of interest.

On a large portion of the system it was absolutely impossible to interrupt the car service for any length of time during the twenty-four hours of the day, and it was therefore necessary to devise a method of welding the joints while cars were passing over the rail. This was accomplished by means of a bridge, which is shown in Figs. 1 and 2. This bridge is carefully fitted to the rail and is se-

curely held in place by bolts. Long, tapering approaches are furnished at both ends, so that cars have no difficulty in passing over without interfering in any way with the joint underneath. The mould proper is of a new design, and consists of three main parts. These are shown upon the ground in Fig. 1, and attached in place to the joint in Fig. 2. The parts can be placed in position around the joint ready for the pouring in a very few minutes. They are held together by bolts, and in addition a small clamp is used for supporting the under piece.

Before the moulds are placed in position the ends of the rails are carefully cleaned and polished by means of a sand blast, which is also of recent design. This blast is operated by a gas engine, and with it the rails can be burnished and made absolutely clean in about a minute. The very best grade of sand obtainable is used with this machine. This blast opens the pores of the steel at the ends of the rails, thus giving a better opportunity for the welding or fusion of the cast iron and steel.

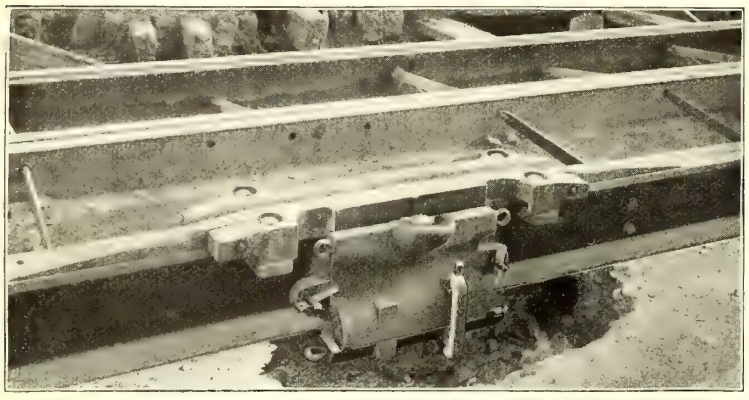

FIG. 2.—JOINT READY FOR CASTING

FIG. 3.—CUPOLA IN OPERATION

The cupola for heating the metal is illustrated in Fig. 3, and the method of pouring is shown in Fig. 4. The cupola contains a number of improvements, and is giving excellent satisfaction. The process of pouring is very simple, although quite ingenious. The ladle or pot for holding the molten metal is attached to two long rods, one of which has two branches at its end, as shown in Fig. 4. The rods are carried by means of two wooden poles, having at their centers an eye or staple, through which the rods are inserted. Five or six men are required to carry the ladle from the cupola to the joint to be welded, and four men are employed in the actual process of pouring; two to support the ladle, one to tip it, and the other to closely watch the process and regulate the flow of metal. From 200 lbs. to 205 lbs. of cast iron are poured into each joint.

The finished joint is shown in Fig. 5. After the metal has become thoroughly cooled, which occurs in a very few moments after the pouring, the bridge and mould are taken off, and the joint is carefully trimmed and smoothed with heavy files. Concrete is then thrown under the base of the joint and the ends of the rails, and carefully tamped into place so as to support the entire joint.

FIG. 4.—CASTING JOINT

In a recent interview, Mr. Robertson, superintendent of the Third Avenue Railroad Company, expressed himself as very much pleased with the results so far obtained with the Falk joint. He stated that a large number of the joints had been installed since the first of January, 1899, and since that time had been exposed to a change of temperature from 8 degs. below to 50 degs. above zero, and during this period not a single joint had broken, while the rail has kept in perfect alignment throughout the different changes of weather, although there has been no paving done of any account.

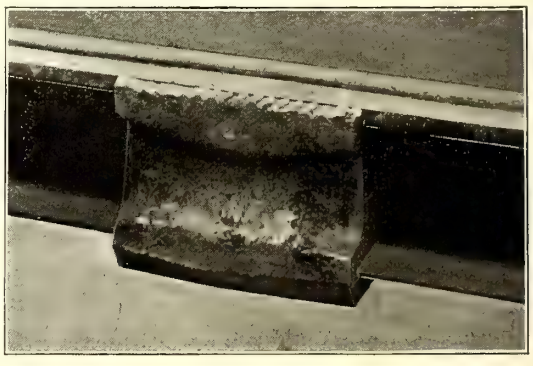

FIG. 5.—COMPLETED JOINT

The annual convention of the Southwestern Gas, Electric and Street Railway Association will be held in Austin, Tex., on April 19-21, 1899. In connection with the convention, an electric, gas, water-power, light and heating exhibition, lasting from April 19 to the 29th, will be held under the auspices of the Austin Commercial Club. Much time and labor has been expended in the effort to make this convention unusually valuable.

Electric Street Railway in Bahia

Sao Salvador de Bahia, the principal city of the Brazilian province of Bahia, is about 800 miles north-northeast of Rio de Janiero, and has a population of about 250,000 inhabitants. The city is the terminus of a number of railway lines, and possesses an enormous export trade in the many staples of the country, such as tobacco, coffee, cocoa, sugar and hides. The harbor is one of the best in America and is crowded with steam and sailing vessels of all nations. The Hamburg South American Steamship Company, the North German Lloyd, Royal Mail, Lambert & Holt and other steamship companies run regular lines to this place. A large part of the import and export trade is in the hands of German merchants.

The city, when seen from the sea by the approaching traveler, presents a beautiful panorama, consisting of the upper and lower city. The former lies for the greater part upon a long half-moon shaped plateau, rising from a narrow strip along the coast about 1 mile long and 700 ft. wide, on which is the lower city. Here is located the business district, including the warehouses of the merchants, the custom house, arsenal and railroad station of the Sao Francisco Railway, which connects the city with the interior. Further along the shore of the bay this narrow strip contracts until the base of the hills forming a plateau seems almost to meet the sea. The streets in the lower city extend parallel to the bay for a distance of about 1½ miles, when they terminate in a mountainous peninsula on which are located the rich suburban towns Bom Gosto, Roma, Boa Viagem and Itapagipe, as well as the famous Bom-Fim Church, or cathedral, the objective point of many pilgrimages on every holiday. In January, when the great Bom-Fim festival occurs, the traffic toward this cathedral is enormous, both day and night.

The upper city is situated at a height of from 200 ft. to 300 ft. above the lower city, and contains the residential quarter, being cooler, dryer and luxuriant with orange and banana orchards. Here also are the principal government buildings.

The upper and lower cities are connected by hydraulic cable inclined railways, steps for foot passengers and a few roads with an average grade of 5 per cent for vehicles.

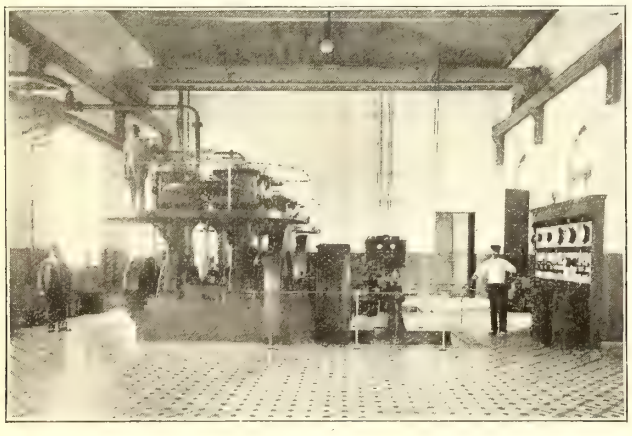
The favorable impression made by the view of the city as seen from the sea is dispelled as soon as the traveler lands in the lower city. He finds here no regularly laid out quays, no wharf cranes, such as one is accustomed to associate with the handling of merchandise, and no regular arrangement of the streets. The buildings look as if they had been erected by Indians, and the hoists for loading vessels are operated by treadmills, with negroes as motive power. A striking contrast to this conglomerate appearance is afforded by the upper city, which is laid out with beautiful streets lined by handsome villas.

VIEWS OF BAHIA ELECTRIC RAILWAY

The tramway system of Bahia consists of a single line traversing the lower city, running parallel to the sea, and extending to the outer terminus of the Itapagipe peninsula. It has a total length of 13.7 miles of track, occupying 7.7 miles of street, and is owned by the Companhia Carris Electricos, formerly the Companhia Vehiculos Economicos. When using animal power this company had considerable difficulty in taking care of its traffic, especially on Sundays and holidays, when the demand for transportation is always great. Moreover, about three years ago the stock of mules which was formerly used suffered from a severe epidemic, so that the question of electrical equipment immediately became an imperative one, and the company gave a contract for its electrical equipment to the Siemens & Halske Aktien Gesellschaft, of Berlin,

In June, 1896, the contractors began their work of electrical construction, which proved to be no easy task, on account of the heavy falls of rain which occur in South America during the tropical winter, which commences in March and extends until August, as well as the difficulty of securing intelligent and desirable labor. These difficulties were aggravated by others, including that of securing transportation of materials. In Bahia only one kind of wagon or truck is used, namely, two-wheeled carts called *carossas*. These wagons are mounted on enormous wheels and can carry at most only about 35 cu. ft. of merchandise, so that transportation is exceedingly expensive. Added to these natural drawbacks, there were others which augmented materially the difficulty of installation. The existing track on this railway was in an extremely bad condition, so that an attempt to repair it would have entailed much more labor than the laying of new track. In addition, a considerable portion of the line extended through the small streets of the lower city, already mentioned. These streets had a width of only 16 ft., and lying between the sea and the base of the hills, formed the only connection between the lower city and the populous suburbs which it was desired to reach. In this narrow space were located the warehouses of the tobacco exporting firms, which, with their *carossas*, practically blocked the street and prevented the laying of track. All efforts to do this and thus interfere with the existing order of things were naturally followed by streams of invective poured upon the tracklayers by the native truckmen, as well as frequent quarrels and disputes.

In spite of all these difficulties and the hindrance caused by them, half of the railway, the Roma-Itapagipe section, was put in operation in the early part of March, 1897, and the opening of the entire line followed on June 6, 1897. On part of the old route the existing track was used. This consists in part of chair construction, the chairs containing jaws in which the rail is held by means of a wedge. Opposite chairs are connected together by a tie rod. Besides this there are 6½ miles of new track laid with T rail, with angle plates and metal ties.



VIEWS OF BAHIA ELECTRIC RAILWAY

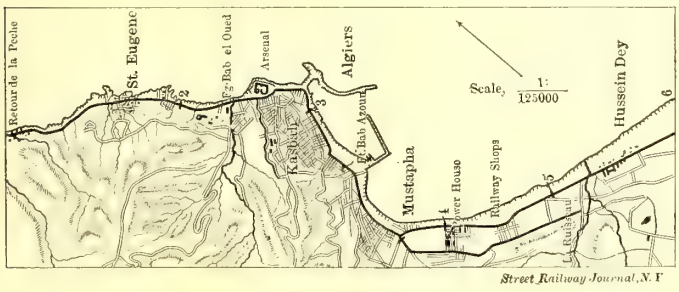
No feeders are used in the overhead system. The trolley wire is carried partly on span and partly on bracket poles, and partly on wall rosettes. The poles are set in concrete.

The power station is located about the center of the line, at Roma, and is 700 ft. from the sea. It is on the corner of two streets, is of hewn stone, and contains a stack 130 ft. high. Adjoining the power station is the car house, with room for twenty motor cars and pit room for nine cars, behind which is a storeroom and repair shop.

In the power house are two vertical compound con-

INTERIOR AND EXTERIOR OF POWER STATION

densing engines of 150 h.p. and 180 h.p., built by Burmeister & Wain, of Copenhagen, with direct-coupled type J 76 machines. The engines make 190 r.p.m., have Corliss gear, and cut-off controlled by a flywheel governor. The sea water for condensing is taken from the bay through a duplicate set of pipes, which extend 250 ft. into the sea in order to secure deep and clear water. In this distance they pass a coral reef, within which the water at ebb tide is too low, and during storm too tempestuous, to be used. The pipes terminate in a crib of wood, which is also used as a dock for the receipt of fuel.



The boilers are of the water-tube type, built by the Babcock & Wilcox Company. The feed water is taken from a spring which is near the boiler house. Both engine and boiler room have space for 300 h.p of additional equipment.

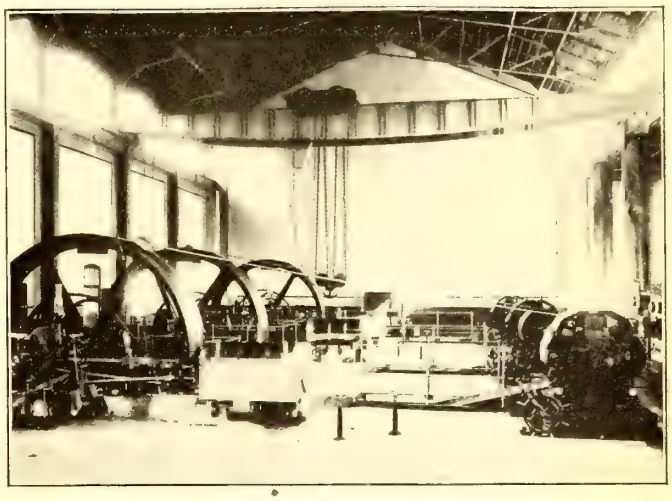
At present there are twelve motor cars, which, on account of the climate, are open. Of these ten are equipped with one 20-h.p. and two with two 15-h.p. motors. Each motor car holds twelve passengers. Experience has shown that the number of motor cars is not sufficient to carry the traffic, and orders have been placed for six additional motor cars and a third engine.

The electric system is very popular with the inhabitants, especially since none of the fears first felt in regard to the use of electric power have been realized. The European system of fares is in force, by which each passenger is given a fare receipt, which he keeps, and which is afterward inspected by a controller. The operation has been carried out with great regularity and safety, even during the continuous festival of the Bom-Fim in January, with an enormous traffic, and many encomiums were passed on the excellence of the equipment.

Electric Railway in Algiers

The Société des Chemins de Fer sur Routes d' Algérie is the title of a French company, which operates an interurban railway system in Algiers, Africa, connecting that city with a number of neighboring towns. The line, which is operated mainly by steam power, has a total length of 170 km. (107.4 miles), but in addition several important extensions are projected and in part under way, which will considerably increase the total amount of track. The government concession for this railway was given May 1, 1891, but on March 9, 1897, was so modified that the company was permitted to use electricity on that part of its system

MAP OF ALGIERS



which connects St. Eugéne, on one side of the city, with Le Ruisseau and Hussein on the other, and including the connecting link in the city itself. The contract for the necessary equipment was awarded to the Société Anonyme Electricité et Hydraulique, of Charleroi, Belgium, which, with its corresponding French company, the Société Anonyme Transmission, Transport et Traction, commenced work toward the end of 1897.

Electric operation of the line was begun commercially on Sept. 23, 1898, after considerable delay occasioned by the complete loss of the structural iron for the power station, which sank on the "Gallia" Feb. 1, 1898, while being carried to Algiers. This disaster necessitated the duplication of this part of the plant.

TRACK AND OVERHEAD CONSTRUCTION

The entire length of the sections upon which electric power has been substituted for steam power is 15.7 km. (9.7 miles). The principal line, which connects Deux-Moulins with Nouvel-Ambert, has a length of 12.3 km. (7.6 miles), and is double tracked, with the exception of a short distance near each end.

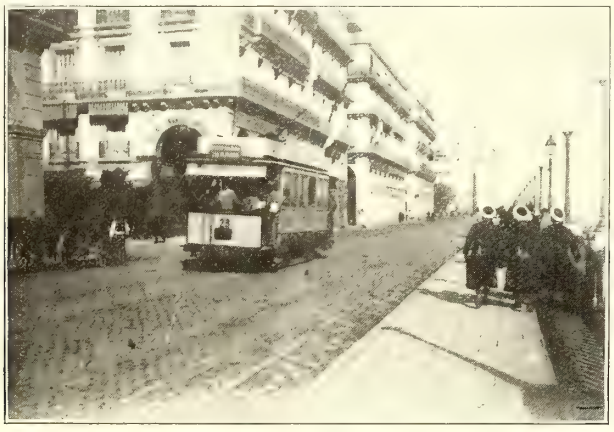
The cities of Algiers, St. Eugéne and Mustapha are located on the Bay of Algiers, the shore of which, a short distance from the water, rises rapidly, leaving a narrow band only of comparatively flat territory between the base of the hills and the sea. This circumstance confines all

INTERIOR OF STATION

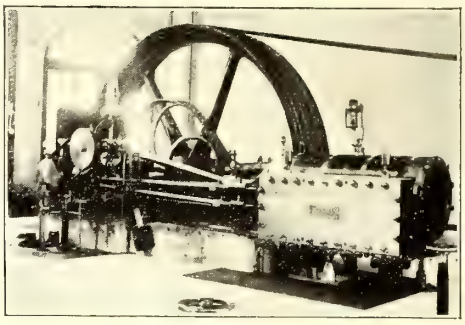
the traffic between the cities to near the coast, with the result that the new electric line enjoys an extremely large business. When formerly operated by steam, trains were run every fifteen minutes, but the headway of the electric cars is now five minutes, each car drawing a trail car.

The climatic conditions of Algeria are not particularly favorable to the operation of electric cars. In summer the prevailing winds are from the south, especially during the season of the *sirocco*, and, coming from the Sahara, are laden with a fine dust, which penetrates everything, and, getting in the journals of the cars, and, in fact, of all machines, materially shortens their life. On the other hand, in winter the country is subjected to almost continuous rains, which, falling with tropical fury, frequently convert the streets into regular rivers. As a result, the cars often have to run for a half mile or more in water half a meter (20 ins.) in depth. Again, certain parts of the track are in constant danger of being undermined by the sea during a storm. During the month of March, 1898, the rails were torn up for a distance of more than 100 meters (330 ft.), and often the spray from the waves is thrown against the electric cars.

The profile of the road does not present any remarkable features. The steepest grade is about 4 per cent for a distance of about 132 meters (425 ft.). The minimum curve radius is 28 meters (91.6 ft.).



The track in the center of the city is laid with Broca rail weighing from 36 kg. to 44 kg. per running meter (72.7 lbs. to 88.9 lbs. per yard).



The ties, which are 1 m. wide x 0.1 m. deep (39 ins. x 3.9 ins.), are of metal and spaced 2 m. (6 ft. 7 ins.) apart. They are bolted to the rails and intended to keep the gage perfectly accurate. The track is laid on a continuous bed of concrete with hydraulic cement.

Outside of the city the company uses a Vignole or T rail of 20 kg. per m. weight (40 lbs. per yard), laid on wooden ties spaced 0.8 m. (2 ft. 7 ins.) apart. The gage is 1.055 m. (3 ft. 6 ins.), and on a double-track road the distance, center to center, is 3 m. (9 ft. 11 ins.).

Each joint is bound with two copper bonds of 8 mm. diameter (No. 0 B. & S.), connected to the rail by conical bonding chucks. Every 30 m. (98 ft.) the two rails of the same track are cross connected by a wire of the same size. On certain sections of a single track where the Vignole rail is used, the conductivity of the return circuit has been increased by the use of a return conductor made up of old rails buried in the soil, and bonded in the same way as the regular track. The use of buried bare cables as return conductors has not been looked upon with favor by the engineers. The return circuit as installed has been satisfactory, and on no part of the line has any difference of potential between the rails and the earth of over 3 volts been noticed.

A map of the line is given on the preceding page. The station is located at *C*, which is 8 km. (5 miles) from one of the termini. On the entire length of the route, even where single track is used, two trolley wires are employed, of 8 mm. diameter. The overhead system is divided into six sections of about 2.5 km. (1.5 miles) each. Three of these, viz.: one to two, two to three, and five to six, are supplied with separate feeders; in the case of the first two, by 150 mm. sq. (300,000 c.m.), and in the latter, where the difficulty is less, 50 mm. sq. (100,000 c.m.). The other three sections have no feeders. In the open country the feeders are bare wire, carried on porcelain insulators, but within the city they are buried, insulated by a layer of jute and paper, saturated with asphalt and protected by a lead sheath and outside steel wire armor. In spite of the excessive heat, which in summer is sometimes as high as 38 deg. C. (110 deg. F.) in the shade, the insulation of the cables has remained in good condition. It is doubtful whether a rubber insulating cable would have given such good results under the same conditions of temperature. The length of the underground feeders is 7400 m. (24,000 ft.), and they were supplied and installed by the Société Industriele des Telephones, of Paris. Each of the six independent sections into which the overhead line is sub-divided is protected at the power station by an automatic circuit breaker, so that any short circuit on one section will not interfere with the operation of the rest of the system. The overhead line is constructed for the use of the Dickinson trolley, and the distance between the wire and the car axle in no case exceeds 2½ m. (8 ft. 3 ins.). About 9.1 km. (5.6 miles) of overhead line is span construction, the other 6.6 km. (4 miles) bracket construction. All poles, even those in the suburbs, are steel tubes.

VIEWS IN ALGIERS

POWER STATION

Owing to the difficulty in finding a convenient site large enough to accommodate the power station and car houses together they have been located at different points along the line. The station occupies an area of 1600 sq. m. (17,200 sq. ft.), of which 710 sq. m. (7630 sq. ft.) are taken by the engine room, 550 sq. m. (5910 sq. ft.) by the boiler room and coal storage bin, and 340 sq. m. (3650 sq. ft.) for the court occupied in part by the cooling plant and the base of the stack, which has a height of 45 m. (148 ft.) and an internal diameter at the top of 2 m. (6.5 ft.). In the basement under the engine room are located all the feed and steam pipes.

The boilers, to the number of six, are connected in batteries of two each, of the French or elephant (bouilleur superposé) type. The heating surface for each boiler is

100 sq. m. (1076 sq. ft.), and the grate surface is 2.56 sq. m. (27.5 sq. ft.). This type of boiler was adopted after considerable investigation, as being the best adapted to steam generation in any country like Algeria, where the greatest simplicity of construction and ease of operation and maintenance are necessarily of great importance. They maintain the steam pressure very constant in spite of rapid variation in the load. The normal evaporation is 1200 kg. (2640 lbs.) per hour per boiler. Four other boilers of the same type are being installed.

One feed pump of the Worthington type is used, with an injector installed as a reserve, each having sufficient capacity for the entire plant. The feed water is taken from a well, a sheet-iron reservoir carried under the roof of the boiler, or from a cistern with a capacity of 200 cu. m. (52,800 gals.). The normal steam pressure is 7½ atmospheres. The boilers are guaranteed to 9 atmospheres and tested to 15 atmospheres. The piping is of steel and copper, and is duplicate.

The engines are of the simple condensing type, with steam-jacketed cylinders, and the cylinder dimensions are 500 mm. x 1000 mm. (19.7 ins. x 39.4 ins.); they run at 100 r.p.m.; the steam admission for 100 h.p. is 0.04; for 200 h.p., 0.12, and for 300 h.p., 0.25. The fly-wheel has a weight of 12,000 kg. (26,400 lbs.), and the diameter of the shaft is 20 cm. (7.9 ins.).

The condensing apparatus is placed in the basement, but all valves are to be operated from the engine floor. In case of necessity the condenser can be cut out of use and the engines made to operate automatically with free exit.

The air-pumps discharge the hot water into several small hot wells constructed between the foundation pillars. From there it is taken by a small centrifugal pump operated directly by a steam engine, and pumped to a height of 12 m. (39 ft.) into a cooling tower. This apparatus is composed of 540 triangular tubes 7 m. (23 ft.) in height and surrounded by cloth. They are placed vertically in a framework of wood. The hot water, arriving at the top, is spread over these pipes, and is cooled by running slowly along the cloth. A large zinc tank catches the cooled water, which then flows into a cistern, from which it is again pumped by the condensers.

The engines are belted to three six-pole, compound wound generators of 200 kw. each, turning at 450 r.p.m. The output is 350 amps. at 575 volts.

The switchboard is of the panel type, and carries automatic circuit breakers, ammeters, etc.

ROLLING STOCK

The company has in actual service thirty motor cars and eighteen open trail cars. The motor cars contain seats for twenty passengers and room for eighteen standing passengers. The car body is divided into three compartments. The wheel-base is 1.80 m. (5 ft. 11 ins.). Each car is equipped with two 30-h.p. motors, permitting the motor car to draw two open trail cars if necessary. Fully loaded, the weight of the entire train is about 20,000 kg. (44,000 lbs.). The controllers are of the series parallel type.

CAR-HOUSES

The car-houses are situated on the line of route of the road, and adjoining them is a repair shop equipped with all tools necessary for ordinary repairs, and driven by an electric motor.

The change from steam to electric traction has been followed by a large increase in the receipts. The report of the system for the month of December, 1898, shows the following figures; coal per train-km., 2.150 kg. (7.8 lbs. per train-mile); coal, per kw.-hour at the switchboard, 2.5 kg. (5.5 lbs.).

The Breakage of Car Axles

BY J. F. THOMPSON.

Opinion among manufacturers of car wheels and axles differs as to whether iron and steel axles crystallize in service, but, taken as a whole, seems to be against the theory, or, at all events, that the cause for failures in street car axles is not due to crystallization, but to insufficient inherent strength. While this cannot be said to have been proved, the advocates of the theory of non-crystallization claim that if axles break in use and the fracture shows crystallization, that the same axles if tested before being put into service would have shown the same characteristics. It is certainly true that new axles, upon being broken, do show a crystalline structure, proving that service is not necessary to acquire it. On the other hand, a great many axles which have been in use for some time have broken suddenly where the fracture, though fresh and bright, showed no sign of crystallization.

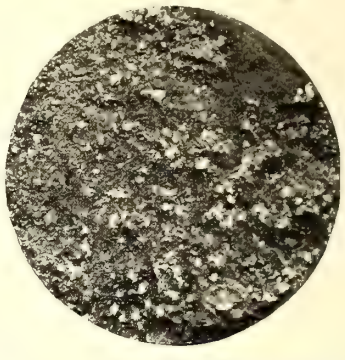
It should be remembered that the car axle, when in place under the car, with the motor attached, is practically rigid, and unlike that under steam railroad cars, because it cannot bend or take up any shock in the middle. When, therefore, an unusual strain or shock occurs, the break in the axle comes at the weakest point, which is sometimes on the

FIG. 1.—FRACTURE OF FINE STEEL AXLE

outside of the wheel next to the journal, and sometimes on the inside, according to the style of motor used. In all cases in the use of steel axles, shoulders and sharp corners should be avoided by the use of fillets as far as possible. In many cases the key-way is cut at a point so that it extends up to the inside hub of the wheel, and if the wheel is fitted to a shoulder, the axle frequently breaks at this point.

The accompanying engravings, which are full size reproductions of actual fractures of car axles, will give an idea of the appearance of the fracture of different kinds of axles. In each case the axle has been turned down somewhat to admit of breakage, so that the diameter in the engraving is not that of the original axle.

Fig. 1 shows the surface of a broken axle from an electric car. The diameter of the wheel fit was 3⅝ ins.; diameter between hubs, 3½ ins; diameter of journal, 3½ ins. The axle broke back of the hub. A piece of the axle, 15 ins. long, could not be broken under a drop hammer of 1850 lbs. falling 12 ft., although the hammer was reversed several times. It will be noticed that the grain of the steel is quite fine. The material is fair and the axle undoubtedly broke because of the shoulder at the back of the hub where the axle was turned down ⅛-in. smaller than the wheel fit. Fig. 2 is a sample of a broken motor axle from a street railway company in Pennsylvania. This axle had a 3¾-in.



wheel fit and 3-in. journal and it broke at the end of the journal next to the dust guard. It will be noticed that the grain of the metal is coarser than that shown in Fig. 1. Fig. 3 is a sample from the driving axle of a traction engine and was 4 ins. in diameter back of hub, with wheel seat turned down to $3\frac{1}{2}$ ins. This axle broke back of the wheel at the key-way, which was $\frac{1}{4}$-in. deep. The wheels were 30 ins. in diameter and the gage of track 3 ft. It will be noticed that the grain of the metal is about as coarse as that in Fig. 2.

FIG. 2.—FRACTURE OF STEEL AXLE

FIG. 4.—FRACTURE OF STEEL AXLE

FIC. 5.—FRACTURE OF HAMMERED IRON AXLE

Fig. 4 is an engraving from a photograph of a new $3\frac{3}{4}$-in. steel axle. As will be seen the grain of this metal is a little coarser than that in Fig. 1, but finer than that in Figs. 2 and 3.

Fig. 5 shows a sample of a hammered iron axle cut from a 4-in. diameter journal. It will be noticed that the fracture shows large open crystals.

It is a well known fact that iron castings will stand a better physical test a year or two after they are made than they will soon after casting. It is claimed that at the time of casting, the molecules are disarranged and that it takes time for them to readjust themselves. The evidence is all in favor of this theory, as observations show that where chilled cast iron car wheels break in service from other causes than wrecks, it is quite early in the life of the wheel. It is very rarely than an old car wheel breaks in service unless the flange or thread has become worn very thin. An examination which has been made of a large number of 33-in. steam car wheels that have been in service from fifteen to twenty years, has shown that they were tough under the wheel breaker and were free from cracks or flaws, seeming to prove that there is not only no tendency to crystallize, but that, if anything, the effect of age is to increase the structural strength of the iron. If this theory of the readjustment of molecular formation is correct as to cast iron, it would also seem reasonable to suppose that it holds true also of hammered iron or steel.

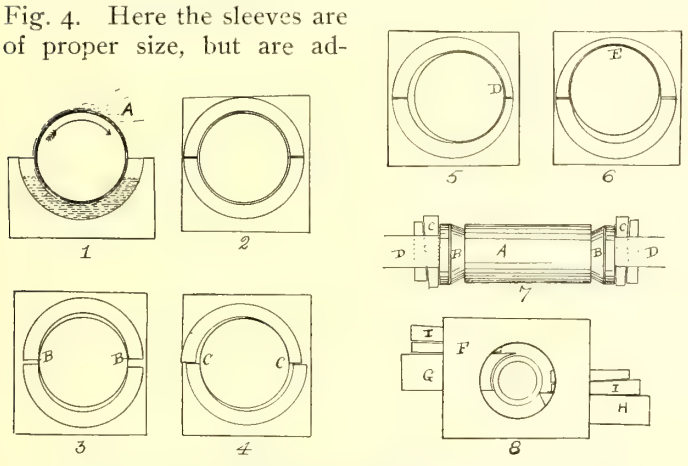
FIG. 3.—FRACTURE OF STEEL AXLE

A great deal could be written upon the importance of employing for the purpose of car axles the best material, and here, if anywhere, a "penny-wise and pound-foolish" policy will tell in the long run against the user of poor material and small axles. The most economical policy is to be generous in the size and material of axles installed, so as to avoid as much as possible any danger of breakage. The curves on electric railways are often of very short radius, and as most of the axles are driving axles, the entrance into these curves at speed may have the effect of twisting off the axle, as well as of breaking the wheel flanges. The latter form the soundest part of a wheel casting, as they are the drag or bottom side in casting, and any strain in curving where flanges generally break, sufficient to break them off, or tending to do so, must cause a severe torsion on the axles.

The axles in most common use are the hot rolled steel and cold rolled steel, both of which have shown excellent results in service. An effort has also been made to employ hammered iron, which has a number of advocates. In iron, fibre is generally considered an indication of strength, and to secure this one manufacturer builds up iron axles by placing together four or nine bars of 2-in. square iron, with a top and bottom piece $4\frac{1}{4}$ ins. x 1 in. or $6\frac{1}{4}$ ins. x 1 in., with corners chamfered to prevent the pile from being overheated. This, it is claimed, will avoid heat cracks, which are almost unavoidable when axles are made from square corner piles. The effect of this axle in use is claimed to be a freedom from breakage, but in point of wear it would probably not have as long a life as a steel axle.

Hollow steel axles have been employed to a considerable extent in steam railroad service, but outside of the third-rail roads of the New York, New Haven and Hartford Railroad have not been employed in surface electric railroading.

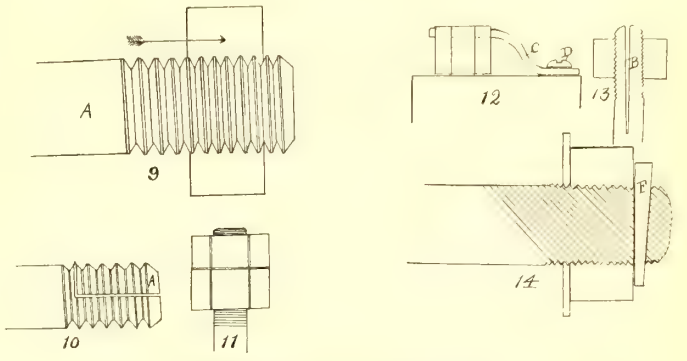
It is a common practice on some roads when pressing wheels on axles to leave them wide in the gage, making the flange run close to the rail. The object of this is to prevent the lateral play of the car as much as possible, and the practice is a good one when the tracks are kept in good condition, are straight and level and the rail joints are kept up well. But the railway manager should remember that the practice of a close working flange is severe on the axle, as the crowding of the flanges against the head of the rail has a constant tendency to bend the axle and wear the flanges. Where there is trouble from either of these two causes, theory would dictate that in pressing on the wheels, a little lateral play should be allowed between the flange and the rail. This should be especially followed on a road where a small-sized axle is in use, and where the labor and



expense of changing the sizes of axles, reboring gears and motor frame boxes and probably the motor frame between the boxes as well, would be so great as to practically prohibit any change in the size of the axle.

Lubrication of Street Railway Car Bearings

BY J. F. HOBART



If a revolving shaft is set up in a reservoir of oil after the fashion shown in Fig. 1, the shaft will take on film after film of oil until the centrifugal force begins to throw the oil off as at *A*. From three to a dozen films of oil will form, according to the conditions. This, as is known, is the theory of all journal lubrication. It is mentioned in this connection simply because the proper lubrication of street railway car bearings has often been prevented through defective mechanical factors. If the sleeves of the car journal fit the axle properly, as in Fig. 2, the oil films can form on the entire bearing surface, and friction, wear and heating are avoided. But sometimes the sleeves of the box are a little too small, so that the edges are in contact with the axle at *B B* Fig. 3, resulting in a scraping off of the oil films as fast as formed. Grinding, wearing, heating and loss of power follow. Oil loaded with grindings will soil the exterior of the box, and, as is often the case, the fault will be attributed to the non-efficiency of the lubricant. The remedy consists either in providing new sleeves of right dimensions or in turning down the small ones to right size.

Another character of defective work is represented in Fig. 4. Here the sleeves are of proper size, but are adjusted incorrectly, as the lower one is not in line with the upper. Two scraping surfaces are therefore produced at *C C*, and wearing, grinding, heating, etc., result. This evil is easily remedied by resetting the sleeves so as to have upper and lower even. The type of worn bushings, illustrated in Fig. 5 at *D*, is a familiar sight to all street railway mechanics. The flow of dirty oil, the rattling of parts, the irregularity of motion and loss of power through friction are the symptoms. Oil films may form readily enough on the contacting surfaces, but with one side of the bushings gone, as at *D*, the best lubricants obtainable cannot operate to advantage. The only remedy is to substitute new bushings or rebabbit the box, providing the box is of the kind that will permit this operation. The same remark is applicable to illustration No. 6, in which the top sleeve is worn at *E*. This is frequently noticed in car bearings, and frequently can be fixed by merely putting in a new upper sleeve, the lower one being all right.

GOOD AND DEFECTIVE BEARINGS AND METHOD OF TRUING BEARINGS

Barrel bushings often cause trouble by expanding or losing their shape through heating. Fig. 7 shows a good way to true such bearings. The bearing *A* is held by means of coned collars, *B B*, on either side. These collars are loose on the shaft *D* and are held tightly against the ends of the bearing by means of steel keys *C C*, the latter being driven into seats cut in right places in the shaft. The bearing is now in condition for truing in a lathe, as the shaft *D* can be secured in the chuck. For a cutting tool, the form shown in Fig. 8 can be used, which tool is available for truing many round shapes. The form *F* is of tool steel and is cut out at one side for the cutting tool *H*, and at the other for the straddling tool *G*. Both tools are held in place by means of keys *I I*.

METHODS OF LOCKING NUTS

So much depends upon the adjusting nuts and set bolts in street railway car journals that a brief discussion of them in this connection may be advisable. Necessarily the threads of bolts taper toward the end from which the thread was cut, and if the bolt is struck at *A*, Fig. 9, with a hammer, it will be observed that the nut, unless prevented by something, will turn a little at each blow. After several blows it will be seen that the nut has moved a little in the direction of the arrow. If the blows are continued, the nut will follow the thread and finally drop off from the end of the bolt. This tendency is overcome, of course, by tightening the nut against something, as the cap of the box, for example. Railway men have considerable trouble with loosening nuts and bolts, owing to the jar. Several ways to prevent nuts and set-screws loosening of their own accord are shown next. Fig. 10 shows a split-bolt tip. The split part *A* is cut from an ordinary bolt by means of a hack saw. The loose piece assumes the form of a wedge and will usually prevent the nut from working loose.

The two-nut, or lock-nut form, illustrated in Fig. 11, is too well known to need describing. The pivoted spring *C*, as shown in Fig. 12, has also been employed with good results. The spring is set-screwed to the cap of the box at *D*. The head of the cap-screw is grooved and the spring slipped into this groove as shown, thus preventing the screw from turning of its own accord. The divided shaft is shown in Fig. 13. The shaft is simply cut down about an inch below the seat of the nut. The sides are sprung out a little, and when the nut is in position, the expansion of the sides tends to retain the nut in place. The keyed form is shown in Fig. 14, in which the place for cutting the key-way is nicely calculated, and when the key *F* is in place the nut is firmly secured from turning off.

A recent compilation in the "Railroad Gazette" places the number of accidents of all kinds on street railways in the United States for the year 1898 at 133; persons killed, 27; persons injured, 378.

Motor-Dynamos or Accumulators

BY ALTON D. ADAMS

It has been truly shown for electric car lines long enough to make the cost of feeders prohibitive, with an ordinary per cent of loss—that an accumulator plant at the end of long feeders may be cheaper to install and operate than a small additional generating plant. Were the only choice, in cases like the above, between an accumulator plant and an additional station, the battery up to distances of 10 or 15 miles would in most instances be selected, but the fact is that a third means is at hand to produce the desired result, and in most cases will be found more desirable than either of the other two; this means is the motor generator.

The accumulator has no power to furnish an increasing pressure in compensation for line loss, and when used to maintain pressure at the end of long feeders must be placed at the point where constant pressure is desired. This isolated position of the battery involves a constant outlay for interest on real estate or rent, and for attendance, though not to the same amount in a given case as would a new generating station.

The average efficiency of the battery under working conditions can hardly be expected to exceed 85 per cent, so that the line must deliver to the battery $1. \div .85 = 1.17$ times the energy required by the car motors. The average loss in the feeders between the generating station and the battery should be decided according to the cost of copper and of power, without regard to the battery, except that the loss of energy in feeders will be somewhat greater, their size being the same, when the battery is used, as 1.17 times the watt hours must be transmitted that would be required without the battery. The drop of pressure in feeders between the station and battery must be compensated for at the station, but this drop, at its maximum, will not be so great with as without the battery, because the battery furnishes current at times of maximum demand, being charged at times of minimum demand, the result being that the average amperes flowing through the feeder is greater, but the maximum current less with the battery in use. As the battery acts at the time of maximum demand, it is an addition to station capacity, but an expensive one, as the price of a battery, plus the value of real estate on which to install it, is quite a number of times that of a dynamo of equal capacity.

A motor generator must be installed at the station so as to raise the bus bar pressure enough to compensate for the drop in the battery feeder and to charge the battery. The battery at the far end of a long feeder may be charged and discharged alternately during the entire working time of the central station each day, or it may be charged only during the time of light load and no load on the trolley, and discharged during the entire time of medium and heavy load. It is also possible to send all of the energy transmitted by feeder into the battery and draw the entire supply for the trolley wire from the battery. The plan of intermittent charge and discharge will allow the smallest battery to be used and give the highest efficiency, as the least energy will then pass through the battery, and be subject to its loss, and the battery may always be nearly charged. It should be evident from the above that a battery at the far end of a long feeder serves simply to compensate for momentary fluctuations in pressure, as it does when used in the central station, but cannot supply a pressure to make good that lost in the feeder, a motor-dynamo being necessary for this last purpose.

Taking a case where the loss is any desired per cent in the feeder on the average, with no battery in use, it is clear that the addition of a battery must lower the efficiency of transmission between power house and trolley, without saving anything in the cost of feeder, the average loss in the feeder being at least the same as without the battery, and the battery loss being added to the average feeder loss.

The above facts may be illustrated by the case of a long feeder delivering current to the trolley wire at 500 volts, and with a loss in the feeder of 20 per cent at average load, with no battery in use. Since the average loss in this feeder is 20 per cent, the pressure at the power house must be $500 \div 0.8 = 625$ volts at average load, and no battery in use.

If the maximum load on this feeder is twice the average load, the pressure loss in the feeder at maximum load will be doubled, or $(625—500) \times 2 = 250$ volts, and the pressure at power house must be $500 + 250 = 750$ volts at maximum load. Since the volts lost in the feeder and the current or amperes flowing in it are each twice as great at maximum load as at average load, the capacity of the motor-generator must be four times as great for the maximum load as for the average load. The total power or energy lost in the feeder is equal to the average loss, that is, the loss at average load, and the maximum loss simply serves to fix the capacity of motor-generator necessary.

Suppose, now, a battery is installed at the trolley end of above feeder, and so arranged that all of the energy from the power house goes into the battery, the average efficiency of battery being 85 per cent. Taking the most favorable view for the battery, suppose the average ampere load on the feeder remains the same as without the battery, and that the loss in battery is entirely made up by increased pressure at the power house. Since the battery is to deliver 500 volts to the trolley with 85 per cent efficiency, the pressure at which current is delivered to the battery must be $500 \div .85 = 582$ volts, and the pressure at the power house at average ampere load on feeder, which is the same as average ampere load without the battery, must be volts lost in feeder, plus volts lost in battery, plus volts delivered to the trolley wire, that is $125 + 82 + 500 = 707$ volts at power house. The efficiency of transmission between the power house and trolley when no battery is in use is $500 \div 625 = .8$, or 80 per cent, while when the battery is used the efficiency of transmission is $500 \div 707$, equal to 70.7 per cent.

The loss between power house and trolley without the battery in use is 125 volts, and with the battery 207 volts, so that the loss with the battery is $207 \div 125$, equal to 1.65 times as great as without the battery. If it is desired to put the same total average loss with the battery in use, that is 207 volts, into the feeder with no battery in use, the relation between the area and weight of the feeders required for the two cases may be found as follows, when A = amperes flowing through feeder at average load in each case, L = total length of feeder wire in feet, and 11 = resistance in ohms of a mil-foot of the conductor. Then the areas of the feeders will be:

$$\text{C.M.} = \frac{\text{L 11 A}}{125} \text{ and } (\text{C.M.})_1 = \frac{\text{L 11 A}}{207}$$

$$\text{Therefore C.M.} : (\text{C.M.})_1 :: \frac{\text{L 11 A}}{125} : \frac{\text{L 11 A}}{207}$$

$$\text{C. M.} \frac{\text{L 11 A}}{207} = (\text{C.M.})_1 \frac{\text{L 11 A}}{125}$$

$$\text{C.M. } (125) = (\text{C.M})_1\ 207 \qquad \frac{(\text{C.M.})_1}{\text{C.M.}} = \frac{125}{207} = .60.$$

That is, if the battery is not used in above case, and the total average loss of 207 volts that would take place in the battery and feeder combined, concentrated in the

feeder, the area and weight of feeder will be only 60 per cent of what it would be with the battery in use. Should it be desired to maintain the same loss in feeder without as with the battery, the weight of feeder will remain the same, and as the efficiency of transmission is 80 per cent without the battery and 70.7 per cent with it, the amount of power required in each case when 1000 h.p. is delivered at the trolley is with no batteries in use, 1000 ÷ .8 = 1250 h.p. delivered to the feeder at the power house, and with the batteries 1000 ÷ .707 = 1413 h.p delivered to the feeder at the power house. When batteries are used, therefore, additional power to the extent of 1413 — 1250 = 163 h.p. must be applied to the feeder, beyond what would be required without batteries. Assuming the average power to be required during 6000 hours per year and that the cost of power is 1 cent per h.p. hour, the yearly value of the additional power lost by the use of batteries is found from 6000 × 163 × .01 = $9,780.00 per year.

As the above computations are based on the assumption that all of the energy on feeder from the power house goes into the battery, and is subject to the battery loss, the results obtained will vary from the above when only a part of the energy from the power house goes into the battery and the remainder directly into the trolley wire. In case but half the energy from power house goes into the battery, the possible saving in copper and the extra cost of power above found will each be reduced one half. In order to maintain a pressure of 500 volts on the trolley wire at the end of a long feeder, a motor-generator must be used to supply the entire loss of pressure between the power house and trolley, at the maximum load, whether a battery is used or not. The capacity of the motor-generator in any case must equal the maximum current in amperes on its feeder multiplied by the maximum loss in volts between the station bus bars and the trolley wire.

In the case above taken of 125 volts lost on feeder, at average load, with no batteries, assume the maximum load twice the average load in amperes, and let A equal the amperes at average load, then the capacity of motor-generator for average load is 125 A, and at maximum load, with twice the amperes flowing in the feeder and twice the volts lost in it, the capacity of motor-generator is 2 (125) 2 A = 500 A; that is motor-generators must be four times as large as needed at average load in order to maintain pressure of trolley wire for the maximum load.

When a battery is used at the trolley end of above feeder, as assumed, the load on the feeder need not rise above the average, and if all the energy is sent from the feeder into the battery, the total loss of pressure will be 207 volts, as computed, and the capacity of motor-generator must be 207 A, the amperes being the same as with average load and no battery.

For the assumed conditions, then, the motor-generator without battery must be 500 A ÷ 207 A = 2.41 times as great as when a battery is used.

The losses in the motor-generator will be about the same whether a battery is used or not, and while a larger motor-generator is required when no battery is used, the actual energy in kw. hours furnished by the motor-generator must be greater with the battery in circuit, and the same size of feeder, since the motor-generator furnishes the total loss, which is greater with the battery in use.

It should be held clearly in mind that the total loss for either system is the loss of *average load*, and though the loss fluctuates more between its highest and lowest point, so as to require a larger motor-generator without batteries than with them, the system without batteries has a smaller *average loss*, and is more efficient or else requires a smaller feeder.

Portable Electric Stone Crusher

A rapid and economical method of stone ballasting track has been in use for some time on the lines of the Scranton Railway Company, Pa. The method involves the handling of the stone only once by the use of a portable crusher. The general arrangement of the crushing and distributing car is shown in the accompanying engraving.

An ordinary single-truck freight car is equipped with a trolley pole, stone crusher and three No. 3, 30-h.p Westinghouse motors—two to operate the car and one to drive the crusher, to which it is connected by a 6-in. rubber belt. The car is loaded with stone from the quarry, and is then run to the point of the track which it is desired to ballast, the track having previously been left with exposed ties. The crusher is then set in operation by means of the stationary motor, and the pieces of stone fed into the jaws of the crusher, the broken stone dropping into place between the ties as the car proceeds slowly. The capacity of the car is 6 cu. yds. of stone, and that of the crusher is 50 cu. yds. in 10 hours. The crusher will receive stone 8 in. x 14 in. The weight of the crusher alone is 7000 lbs. After the car has passed the stone is raked into place and tamped under the ties by hand.

PORTABLE ELECTRIC STONE CRUSHER—SCRANTON

Changes in Washington, D. C.

Announcement has been made that the stock of the Metropolitan Railroad Company and the Columbia Railway Company of Washington has been sold to a syndicate organized for the purpose of effecting a consolidation of the electric lighting plants of the District of Columbia, the gas companies of Washington and Georgetown, and all the street railway lines in Washington.

It is understood the price paid for the Metropolitan property was in the neighborhood of $4,000,000, and for the Columbia about $1,000,000. It is understood the capital stock of the new combination will be not less than $25,000,000.

LETTERS AND HINTS FROM PRACTICAL MEN

Notes on the Standard Rules and Regulations as Reported by the A. S. R. A. Committee, III

Schenectady Railway Company,
Schenectady, N. Y., March 19, 1899.

Editors Street Railway Journal:

Continuing the comparison and analysis of the "Standard Rules and Regulations" of the A. S. R. A. committee, we wish to know:

Sixth.—Are they free from contradictions either within themselves or with one another? They are.

Seventh.—Are they in accordance with general usage, experience and observation? This point has already been discussed in the previous article (under the third head) and several instances given where they were *not*. There are one or two instances that need a more extended discussion, and the first and most important of these is the matter of "Bell Signals."

The matter of signals between the conductor and the man who runs the car (as he is called the "motorman" in the rules under discussion we will call him that) is an important one in a general set of rules, and if only one thing were made "standard" that one thing should be the bell signals. To a conductor or motorman who serves for any length of time on a road or roads where similar signals were used, they become a language to him; "two bells" are not two separate and distinct strokes on the signal bell—they are the words "go ahead" as plainly as if spoken by human voice, and when, for any reason, he has to work under another system of signals they are more confusing to him than a command in an unknown tongue.

To the traveling public, also, the ordinary and most-used signals become a like language, very often influencing their actions while boarding, moving around on, or leaving a car. Twice within the writer's knowledge has an unfamiliar signal nearly caused an accident to a passenger hearing and misunderstanding it. It may be urged in regard to the employee that a proper training of a few weeks under the new signals would eliminate the old ones from his memory, but the difficulty is that the long observation of certain signals becomes *more* than a memory; it becomes almost an *instinct*, and takes a long time to supplant with a new system. In a case which occurred under the writer's observation, a motorman who had been trained under "one bell, stop at next regular stopping point," was running on a road where "one bell" meant "stop instantly." He had been in training over two months under the new signals and yet, at a critical instant, when "one bell" had been given him as a signal he involuntarily obeyed the old signal, did not stop instantly, and had a bad collision. The same is true of the conductor—upon seeing the need of a certain action to be performed by the motorman his hand will involuntarily give the signal most familiar to him *at that moment*. To a lesser extent this principle is also true of the other traffic employees and of the traveling public, and illustrates the need of a standard and universal system of signals on all surface railways using bell signals.

It may be urged that to have a full and complete set of signals that can be used on any road is as impossible as to formulate a set of complete rules for the same. Such a complete set of signals is not necessary; all that is necessary is a set of signals for the "traffic messages" (between the conductor and the driver of the car or train) that are common to all surface roads. Special messages, due to peculiarities of the driving apparatus or to local conditions of track, traffic, or rules, can easily be added in each case—as will be shown later.

These standard signals should be easy to learn and ring, should be as simple as possible, and—if it is possible to do so—should be so arranged that awkwardly or incorrectly given they do not cause delays, complications nor accidents. Those requiring instant action should be the very simplest and quickest to give and receive, while those requiring action not so prompt may be more elaborate, and those demanding attention should be in the nature of alarms. At the same time there are a few signals like "two bells—go ahead," "three bells—come back," that are standard and universal, and will have to be recognized and left unchanged even if they somewhat disarrange the order and conditions as just noted.

The actual number of general "traffic messages" necessary to be used between the conductor and motorman is not very great, and can be easily covered with one, two, three or four taps of the signal bell, or with a few repetitions or combinations of these numbers. To find out what is really necessary in the number of these signals, let us see what are the necessary general messages between these two employees.

The car being stopped, the conductor may require the motorman

1. To start it forward.
2. To hold it stopped until some other than the regular starting signal is given.
3. To start it backward.

The car being in motion, he may require the motorman

4. To stop it instantly.
5. To stop it at some pre-determined point.
6. To get ready for a stop (*i. e.*, to shut off motive power or to slow down).

The car being either stopped or in motion, he may require the motorman

7. To come to his assistance.
8. *Not* to stop for passengers desiring to ride.

There are, therefore, at the most, only eight general signals necessary from conductor to motorman—three for use when car is stopped or stopping, three when car is in mo or is just starting, and two at any time. Four distinct signals—such as one, two, three or four taps of the bell, with a repetition of one of them as an alarm signal, will cover the whole ground. As already stated, two of these signals are already in universal use and must be considered standard, and there is *one* that is not standard but should positively be made so, that is the signal for "Stop instantly." Under the "bell signal rules" of the committee we find this given as "three taps of the signal bell while car is running." This is the practice of a number of street railways, many of them quite large ones, but nevertheless it is *not* a universal one, *nor is it the correct one*. It is an undisputed fact that it is necessary on any and every surface street railway to have a signal that will stop the car as quickly as possible; it is as undisputed a fact that on all such roads such a signal is liable to be a danger or emergency signal. It should, therefore, be the signal that is the simplest and quickest to give and to understand, that can be given in any emergency by any one within reach of the signal cord, that will be given correctly and in full, even if the signal apparatus is broken in giving it—and the only signal fulfilling this and all necessary conditions is that of "one bell"—or one tap of the motorman's, driver's or gripman's bell. Any other number or combination or repetition of numbers, given under the excitement of an impending or happening accident may be wrongly given, may be given so rapidly as to confuse or mislead the hearer, or may be misunderstood even if given correctly; but the single "*clang*"

gives no chance for mistake on the part of the giver, nor for misconception nor misunderstanding on the part of the receiver. In time of danger a convulsive and almost instinctive clutch at the bell-cord will give the desired signal —even if it breaks the apparatus—where the more elaborate and unnecessary "three taps" could not be given, completed nor understood.

It has been urged that on surface railways having fixed stopping points the use of "one bell" as a signal for stopping instantly would make many unnecessary stops during rush hours or at other times when the cars were so crowded that the conductor was not easily "get-at-able" by a passenger inside the car, as such passenger would be very liable to give "one bell' when his—or her—desire was only to have the car stop at its next regular stopping place. This is true, and until the new signals were thoroughly standard such a thing would very probably happen, but its frequent occurrence could be easily prevented in many ways, and as the proper signal became better known it would gradually cease. In any event, its occurrence could only cause delay; under no circumstances could it—on a well-managed road—cause an accident.

Therefore, with the above signals fixed, the others arrange themselves very quickly, and the necessary general signals from the conductor to the motorman would be as follows:

(1) One bell, while car is stopped, "Do not start until some other signal than 'two bells' is given."

(2) One bell, while car is running, "Stop instantly."

(3) Two bells, while car is stopped or directly after one bell or three bells have been given, "Go ahead."

(4) Two bells, while car is running, "Get ready for a quick stop."

(5) Three bells, while car is stopped, "Back car."

(6) Three bells, while car is running, "Stop at next regular stopping place."

(7) Four bells, at any time, "Do not stop to take on any passengers."

(8) A succession of quick single taps, or a continuous ringing of the bell, "Come to me instantly."

From the motorman to the conductor the same signals will need to have a different meaning, and from the fact that the same signal cannot be used for two different messages (depending on whether the car is stopped or moving), the signals will have to be a little more complex than those from the conductor to the motorman.

The motorman may desire the conductor

1. To come to him instantly.

2. To put on the rear brake or some other safety or car-holding or car-stopping device.

3. To shut off the motive power.

Or he may wish to inform the conductor

4. That he desires to back the car.

5. That the motive power is cut off from him.

6. That uncollected fares are on the front platform, or have entered car by front door.

7. That some switch, signal, or safety device, known to the conductor and operated by him, is not set or properly arranged.

There are, therefore, at the most, only seven necessary general messages from the motorman to the conductor, and, as stated, these have to be made up of not only single signals of one, two, three, or four taps of the bell, but also of repetitions and combinations of them. With these facts in view the necessary general signals from motorman to conductor would seem to be as follows, at any time and whether car is stopped or stopping, running or just started:

(1) One bell, "Come to me instantly."

(2) A succession of single taps or a continuous ringing of the bell, "Put on rear brakes (or any other safety or stopping or holding device)."

(3) Two bells, "Uncollected fare or fares on front platform, or have entered car by front door." This signal to be followed by slower single taps, giving the number of such fares.

(4) A succession of two bells, or double taps, thus: — — — — — —, "Motive power cut off from me."

(5) Three bells, "I wish to back the car."

(6) A succession of three bells, thus: — — — — — — — — —, "Switch or signal or safety device on line or track not set or not operating."

(7) Four bells, "Shut off motive power."

Any special or local signals can be added to the above lists by additional number of taps, or by other combinations of them than those used above.

The signals as suggested above are the result of a long course of inquiry and observation on this point and are believed to be simple, easy to learn, to ring and to understand. There is a good reason for each one, and for the arrangement as a whole, and the writer would be glad to have them studied and criticised.

No attempt has been made to deal with the signals made by the alarm, or foot-gong, as signals should never be made between the conductor and motorman in this way except in a case where the signal bell or bells are broken so that they cannot be used, and with a double system of bells on each car and with a few feet of bell cord, with "patent splicers" in the locker, there is absolutely no occasion for this to occur. The specific reason for not using the foot-gong as a signal between conductor and motorman is that the sound of the gong is liable to be so overpowered by outside noises as to be inaudible to persons on the car, and the strokes on the gong are also liable, if heard, to be confused with those of other cars passing, thus leading to confusion, mistakes and accidents. Outside its use as an instrument of warning and alarm, the gong should be used only as a signal to a car behind, in front, or passing; as an acknowledgement by the motorman of the receipt of the conductor's signals, and to ask permission of the conductors to start the car. For the first of these purposes there is no need of any general or standard set of signals, the use of the gong for this purpose will be entirely local and special, and can therefore be arranged by each road for itself. For the second of these purposes the use of the gong should be insisted upon, and should be made part of the general rule for "signals," as follows:

"He (the motorman) will always acknowledge the receipt of all signals from the conductor by repeating them *at once* on his gong, and *exactly as received by him.*"

This not only gives the conductor the opportunity to know that his signal has been received and correctly understood, but it lessens the chance of careless mistakes on the part of the motorman—such as receiving and understanding one signal and putting into effect another one—by making him repeat the signal himself and thus bring it more clearly to his own attention. It also calls the attention of a car or of vehicles or of pedestrians in front of the car to the signals and enables them to take advantage of it in crossing, not crossing, or getting off the car track. In case, also, that the motorman receives from the conductor a signal that it is impossible to obey, or that he *knows* is wrong, the reiteration of it on the gong will be the best and speediest method of calling the attention of the conductor to his mistake. For the third of these purposes—that of asking the conductor for permission to start, when for any reason the motorman has stopped without a signal—a part of the general rule for "signals" should be made to apply to it, as follows:

"If for any reason the motorman has stopped the car

without a signal from the conductor to do so or if the car has been stopped on signal from the conductor, and the motorman may desire for any reason to move the car, he must *in no case* start it until he has asked permission of the conductor to do so by ringing on his own gong the signal he desires, and *has received that signal from the conductor*."

The committee has given duplicate rules on this subject (No. 18 for conductors and motormen, and No. 12 for motormen), but has not included in either the matter of asking for the signal by the alarm-gong. With the gong used for these three purposes, the alarm and warning signals should be limited to a succession of rapid single strokes for an alarm warning, a succession of slow single strokes when running in a crowded or narrow street, or when turning a corner, and a combination signal, such as —— ——— for a cross-street warning.

Rule No. 10 for motormen reads—"Signals: Before reaching a curve the conductor will signal you by ringing your bell twice to go ahead if he has the trolley cord in his hand. Should you fail to receive the signal ring the conductor's bell twice. If you fail to get the go-ahead signal, stop your car until you do."

In the first place, the caption of the rule is misleading and incorrect, as its subject is "curves," and it has less to do with "signals" than many others of the rules not so headed. In the next place, there is absolutely no use for such a rule. The "right of way" around curves has been defined in a preceding rule, so it cannot be for that purpose that this rule has been framed. If it is on account of the fact that the overhead work on curves is in such bad shape that it necessitates the conductor hanging on to the trolley cord before the car can proceed around it, the sooner such road discharges its line boss and gets one that will build curves that *can* be run, the better. A rule is no substitute for proper and correct work, and in such a case it is a patch on top of a patch! If the object of the rule is to have the car stop at every curve in order to prevent a collision at the end of it, such object is an unnecessary one for a general rule. *All* curves are not dangerous, even on any one road all curves are seldom dangerous ones. Where curves on any road are dangerous, it will be the special province of that road to make its own special rules for the occasion—no general rule must try to *explicitly* cover local conditions.

Eighth.—Are they reasonable?

Ninth.—Are they just and equitable?

These two heads will be considered together, as most of the rules coming under one come also under the other.

The eleventh paragraph under "General Requirements" states that "All employees should make a deposit of at least ten dollars for the badge furnished them and twenty dollars for cost of uniform." If the idea is to reimburse the employer for the loss, destruction or injury of the badge, the exaction of a ten-dollar deposit for an article worth from fifty cents to a dollar and a half is scarcely reasonable, and is certainly neither just nor equitable. If the idea is to make the sum a *penal* one, it is still less reasonable, as any amount beyond the value of the article could not be collected by law, and its retention by the employer should certainly be resisted by the employee. The just and reasonable method is to make the amount of the deposit the exact cost to the employer of the articles entrusted to the care and used on the person of the employee —such as the badge or badges, the uniform buttons, punch, tickets, transfers, book of rules, etc. Anything further than this is unwise, unjust and unreasonable. Street railways fight tooth and nail against "exemplary damages" when applied to themselves; they should not, therefore, make a precedent by trying to apply them to their own employees.

As to the deposit for uniforms, the language of the rule does not show explicitly whether the committee believes in the railway furnishing the uniform or not. If the former is the case the idea is a mistaken one, as it is now the feeling of both officers and employees of street railways that the employees should always own their own uniforms. Leaving aside the fact that the province of street railways is the carrying of passengers, mail or freight, and not the running of second-hand clothes shops, no employee with any self respect likes to be forced to wear the second-hand and perhaps misfit uniform of another and mayhap dirty predecessor. Every trade necessitates an investment of some sort—of time or tools or materials—on the part of the person learning it, and the investment made by the conductor or motorman is the time given to learn the trade *and* the uniform. For the benefit of itself the employer has the right to require that the uniforms in use *are uniform*, and therefore it should prescribe their exact material and makeup. For the benefit of both itself and its employees, it should make certain that such materials and makeup are the very best for the purpose, and furnished at as low a cost as is possible under such conditions. This having been done, it has the right to insist that the seller of the uniforms be made secure in the payment for them and without responsibility to itself; therefore it has the right to exact a deposit of the exact cost of such uniform, and to pay the seller such cost, thus making certain the fact of payment. Further than this it cannot go in reason and justice, and further than this it owes the employee two other duties in the matter of uniform—*one* is, *not* to require the investment by the employee in a uniform until that employee's situation with the employer is an assured one; and the *other* is, *not* to make the uniform so odd in makeup or material that it cannot be used as "plain clothes" by the substitution of plain buttons and the taking off of the lace or bullion. In speaking of the uniform the cap is, of course, not included; its cost is inconsiderable; it is the one very distinctive feature of the uniform—in fact, in a crowded car it and the cap-badge are the only "outward and visible signs" of the employee—and it can therefore be made as distinctive as the taste of the employer may suggest, without reference to its private use and without financial injustice to the employee.

The single paragraph under "Receivers" and Rule No. 1 under "General Rules for Conductors and Motormen" shows that the committee does not believe in the Biblical maxim as to serving two masters—this point will be touched on later.

Rule No. 8 under same states that "in case of sickness word must be sent to starter at depot by special messenger. No telephone or telegraph messages will be accepted." There are several very minor reasons why this latter condition may be necessary, but they are so minor that the unreasonableness and injustice of the rule as a whole—and especially of a general rule—are apparent at once. The rule should be as follows: "Rule No. —; Absence from Duty.—No conductor or motorman will be excused from duty except his name is posted on the excused list, or except in cases of personal sickness, or of severe sickness or misfortune or death in the family, or for other *unavoidable* cause. In *any* event, he must send word to the starter in such manner as to reach him at least —— minutes before his time of going on duty, and before he goes on duty again he must file with ———————— a written statement of the cause of his absence and be excused by the starter."

This makes the matter a reasonable and equitable one. Under the rule presented by the committee an employee

may have his house burning or burned, his wife in the throes of childbirth or a child at the point of death, he may be drawn as a coroner's juror, detained as a witness, or locked up on a mistaken charge, and, under the rule, he will not be excused from duty. If he is personally sick he must hire a "special messenger" and send "word"—not a written excuse—by him, and all is well. It is true that this may cost him from twenty-five cents to a dollar, whereas a message by a relative, a friend, a fellow-employee, or by a neighbor's telephone would cost him nothing—but that is a small matter to a man who is sick or in trouble, and who is earning from a dollar and a half to three dollars a day.

Under the rule as suggested certain specific reasons and one general one are allowed as an excuse for absence without leave. The employee has, however, a duty to perform toward the employer, viz.: to notify him of his forthcoming absence in time to enable that employer to obtain and place a temporary substitute to perform his duties, and this duty of the employee *must* be fulfilled, but the manner of fulfilling it should not be made onerous nor unreasonable. To prevent undue advantage being taken by the employee of the allowances for absences he is required to present to a specific official a personally written and signed reason for his absence, this specific official to judge of the validity of his excuse, to verify it in case of doubt, to allow him to return to his duties in case he believes it to be bona fide, or to reprimand, suspend or otherwise punish him in case the excuse is not sufficient, valid nor true. The employer is protected in his rights and dues, the employee is treated reasonably and justly.

(To be Continued.)

Formula for Train Resistance

London, March 4, 1899.

Editors Street Railway Journal:

The article in the February number of the Street Railway Journal on Mr. Lundie's new general formula for train resistance seems to call for some remarks from those interested in this subject.

Mr. Lundie's formula is characterized by two marked departures from existing formulæ. It says (1) that the first power of the speed only is involved, and (2) that for equal speeds the resistance involves a term varying inversely as the weight of the train.

With respect to the first; such a radical departure from the present method of estimating train resistance should be substantiated by full accounts of the experiments by which such results are obtained, so that it may be possible to follow the steps by which the conclusion is arrived at. Mr. Lundie gives two sets of plotted results, (a) twelve points being the average of results on a 21-ton car," and (b) ten points, being a "series of actual results, 82-ton train." One would have to know how the different experiments were made, and what governed the selection of the observations by which the twelve points (a) were obtained, before accepting this "average" as the basis for a "straight line" law, especially since the (b) series of observations do not agree with a straight line law, and indicate a law involving a higher power of speed than the first.

Mr. Lundie may have unpublished results which confirm his opinion, but those observations which appear in the figure referred to in the article do not all "cluster around straight line curves," and do not therefore justify the conclusion of the existence of a "straight line" law. In fact the (b) series of observations in Fig. 1 confirm the results of previous investigators, that a higher power of the speed than the first is involved. Those interested in this subject should examine the speed curves obtained by Messrs. Curtiss and Pond, and published in the "Street Railway Review" of July, 1896. These gentlemen made a series of experiments on the Buffalo & Niagara Falls Electric Railway by the "coasting" method, identical with that employed by Mr. Lundie.

With respect to (2), the article refers to Mr. Lundie's experiments on trains of different *weights*, without saying how the trains in question were made up. It would seem that the trains were made up of one, two, three, four and five cars, weighing about 20 tons each. If this were so, the resistance opposed by the air to the passage of the different trains would have an important bearing on the results.

Probably the most reliable experiments that have been made on the subject of the resistance offered by the air to the motion of trains are those made by Professor Goss of Purdue University, and published in recent numbers of the technical journals, *e. g.*, in the "Electrical Review" (London), of Oct. 7 last. According to Professor Goss, the resistances offered by the air to the motion of trains made up of one, two, three, four and five cars is proportional to the numbers 12, 13, 15, 17 and 19 respectively, for equal speeds, and varies with the square of the speed when the speed varies. Hence the resistance in pounds *per ton* is much less for long, and, therefore, for heavy, trains than for short, and, therefore, light, trains. Thus, in trains made up of one, two, three, four and five passenger cars, each 33 ft. long, and weighing 20 tons each, the resistances per ton at 20 miles per hour are 2.4, 1.2, 1.0, 0.8 and 0.7 pounds respectively. If similar calculations were made at other speeds we should find that the longer, and, therefore, the heavier, train had the smaller resistance per pound at all speeds.

It would appear, then, that if Mr. Lundie's experiments were made with trains made up of different numbers of similar cars, like those alluded to, there would be a difference of nearly 2 lbs. per ton between a 20 and a 100-ton train at 20 miles an hour in favor of the heavy train. It is difficult, therefore, to avoid the conclusion that the difference in the resistances found by Mr. Lundie for trains of different weights at equal speeds is not altogether due to the difference in weight, but mainly to the varying air resistance.

Speaking generally, it would seem that the second power of the speed is involved, at least for air resistance, and that for equal speeds the variable depends on the size and the number of the cars more than on their weight.

Chas. A. Carus-Wilson.

The following letter is from the chief engineer of a well-known steam railroad company:

Feb. 27, 1899.

Editors Street Railway Journal:

I have read Mr. Lundie's formula very carefully, and, while it seems plausible, I am not prepared to say that I think it will give a correct train resistance in all cases. I have had so much practical experience with tests for train resistance that I have about given up any hope of a general formula which will cover all cases. I do not doubt that Mr. Lundie's formula is correct so far as trains coasting is concerned, but I doubt very much if it will apply to the general and very varying conditions under which different railroads must operate. I know of one case of a test train where a consolidation engine, weighing about 120,000 lbs., was given its maximum loading over a

long grade of nearly 4 miles, which averaged practically 1 per cent for the entire distance. I have not the figures with me to show just how many tons or how many cars were hauled in each case, but in the first case we took out the heaviest loaded cars we could find, and we will say that the engine hauled 700 tons in sixteen cars. Then we began to take off some of the heavily loaded cars, substituting more cars with lighter loads, and found that the engine would not haul as many tons as it did with the heavily loaded train. Then, in the place of the light loads, we substituted empties, and we found that the engine hauled a still lighter load. This went on until we had reduced the train loading to nearly 600 tons; but when we came to take off all the loads and put on all empties we found that the engine would haul more than 700 tons. Now, this only applies in that one case, and I never saw it in any other; and it is just such things as this, which I have never been able to explain, and for which I have never seen any satisfactory explanation, that makes me doubt any general formula for train resistance. The conditions vary so much on the different railroads for curves, for grades, for wind and for many other things, that I believe each railroad, and, further than that, that each railroad division has got to work out its own train resistance from practical trials in order to arrive at anything satisfactory.

Chief Engineer.

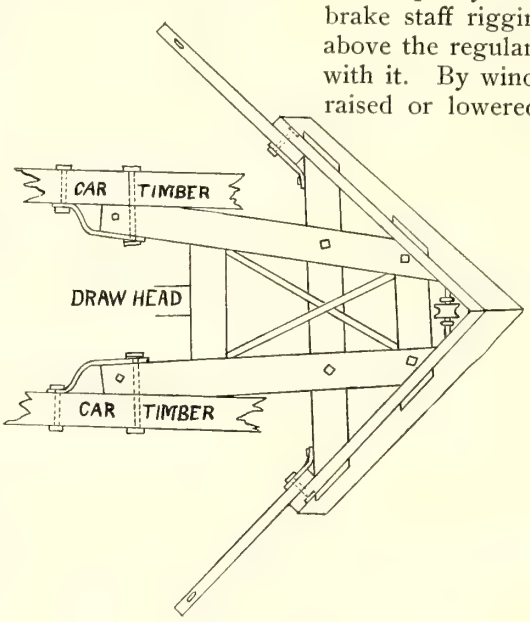

FIG. 1.—PLAN OF PLOW

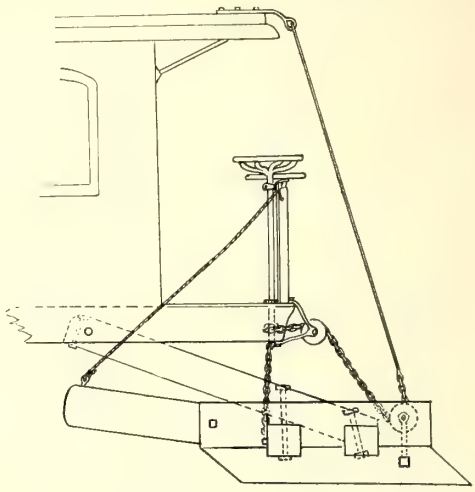

FIG. 2.—SIDE ELEVATION OF PLOW

A Cheaply Constructed Snow-Plow

New Paltz and Walkill Valley Railroad Co.,
New Paltz, Ulster County, N. Y.,
Feb. 21, 1899.

Editors Street Railway Journal:

Our homemade snow plow did such good work in opening up our road after the blizzard of Feb. 13 and 14, and was so simply and cheaply constructed that I believe the idea will appeal to other suburban electric road superintendents.

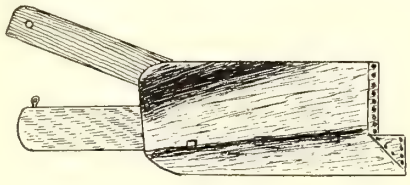

FIG. 3.—PLOW COMPLETE

The sides of the plow are made of 3 in. x 10 in. oak planks, two planks high, the lower planks sloping out, as shown in Fig. 1. The sides are 6 ft. long, and form an angle of 90 degs. at the nose. They are braced by two 6-in. x 8-in. yellow pine timbers (old ties). The back brace is provided with angle irons (not shown), which help hold the bottom side planks in place; two other ties were used for the arms, which are rigidly secured to the plow as shown. On these arms the plow is pivoted to the car body timbers. A header across the arms is so placed as to bear against the drawhead of the car, and thus take part of the pushing strain.

The hood of the car is braced by a pipe from the door header to the end of the plank, which runs the entire length of the car, on which the trolley bases are fastened, Fig. 2. At the end of this plank is secured a rod, which runs to the nose of the plow, where it is attached to a chain, which chain leads around a pulley at the nose and over a second pulley extended from the car platform to an extra brake staff rigging. The wheel of this staff is elevated above the regular brake staff wheel, so as not to conflict with it. By winding or unwinding this staff the plow is raised or lowered with ease. By this arrangement the nose rises faster than the back, which I find not a bad fault, as, when running, if the nose clears an obstacle the back portion will ride up over it.

The wings are of 3-in. x 10-in. oak, 4 ft. long, and are raised by ropes. They do good work in snow up to 3 ft., as they may be raised at an angle and slope the bank, but are not used in 5-ft. or 6-ft. banks.

PLOW IN USE

Fig. 3 shows the plow completed. The sides are covered with $\frac{1}{8}$-in. sheet steel 3 ft. high (made from an old smoke flue). The sheets were shaped by placing them on the track and running one of our 22-ton cars over them. The back upper corners are turned over, and are braced to the arms of the plow. A plow was placed on each end of one of our freight cars, which is equipped with four Westinghouse No. 49 35-h.p. motors and Christensen

air brake. This car was then loaded with 15 tons of railroad iron, and with it we had no trouble in running through snowbanks 5 ft. and 6 ft. high. Our road runs along a side bank nearly its entire length, and we had a continuous drift from 3 ft. to 6 ft. high. The plow opened up the whole road, except a portion in New Paltz, where we have a girder rail on which we could not get traction, and so had to dig this portion open. The rest of the road was of T rail, steam road construction. The accompanying photograph shows one of the largest banks the plow went through, without using a shovel. I estimate this plow saved our company $1,000 during this storm.

E. E. Hawkins, Superintendent.

Armature Hoists and Jacks

Montreal Island Belt Line Railway,
Montreal, Feb. 20, 1899.

Editors Street Railway Journal:

I inclose sketches of two very handy appliances used on our road. Fig. 1 consists simply of a pair of light wheels on which is mounted a frame carrying a chain hoist. This machine is used over the pit in handling motors, armatures, etc., or in transferring motors from one pit or track to another. This takes the place of an overhead crane or derrick. Fig. 2 is a hydraulic pump, and is somewhat similar to a pump described in your columns some time ago. It consists of a lower table mounted on four flat wheels, and an upper rising table lifted by an ordinary hydraulic pump. At each corner of the lower table is a 1½-in. pipe, which slides inside a 2-in. pipe on the corresponding corner of the upper table, keeping the two in line, and making the table very steady. The pump should have a lift of 2½ ft. The tables are of wood, and the entire machine is home made, excepting the jack. I may say that the jack is removable and can be used for jacking cars or any purpose. The wheels of the hoist are flat, so that no rails are required, and any pit can be served. The machine shown in Fig. 2 is all that is needed for the general handling of such motors as the G. E. 1000. With Fig. 1 and Fig. 2 together the G. E. 800 style of motor is easily manipulated.

In shops that are not provided with the necessary cranes, etc., these two contrivances will be found to make a very cheap and good substitute. C. H. W.

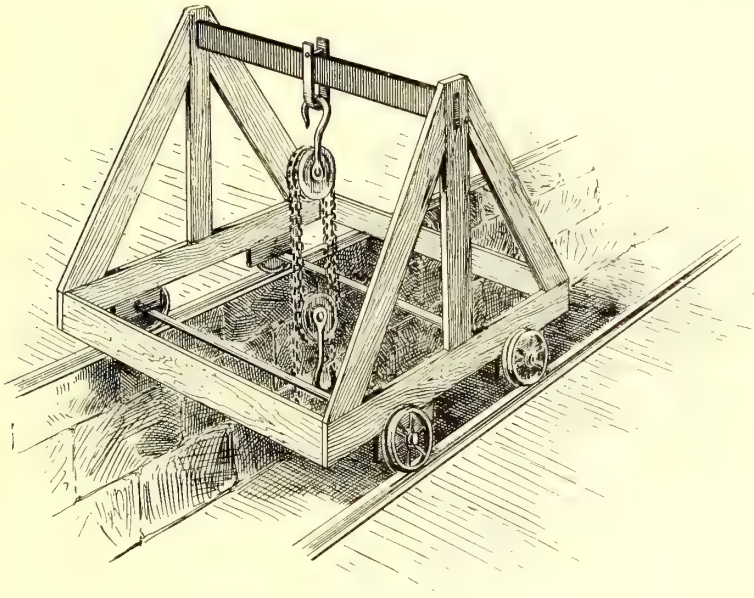

FIG. 1.—PIT HOIST

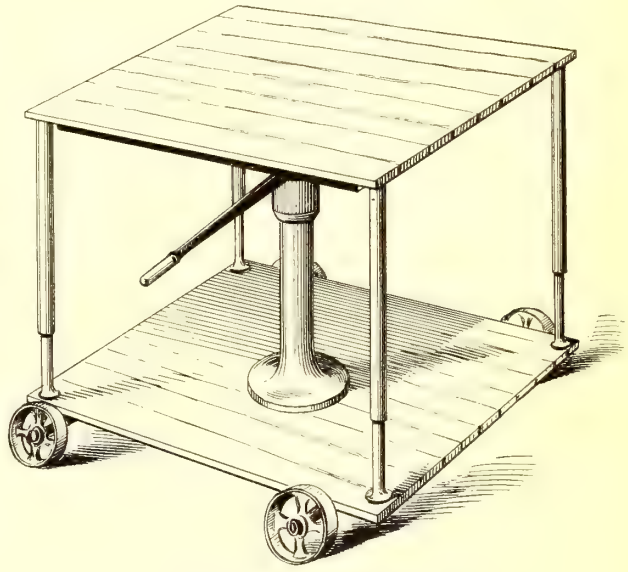

FIG. 2.—PIT JACK

The Man Behind the Controller

Philadelphia, March 6, 1899.

Editors Street Railway Journal:

Observing people who ride frequently in trolley cars have, no doubt, often wondered why there should be such great difference in the motion of different cars running on the same tracks. Sometimes, for example, a car glides along so smoothly that newspapers may be read with ease and passengers may enter and leave the cars without being jostled. At other times the same car (it may be) seems to be possessed with a spirit of evil, causing it to behave in a most erratic and incomprehensible manner, stopping with a violent jerk and starting with a sudden jump. The effect upon the unfortunate passengers, at least those hanging on to the straps, of this alternate jumping and jerking is most unpleasant, and often ludicrous to the observer who may have secured a seat. What is the cause of this strange misbehavior on the part of the otherwise admirable and usually tractable trolley car?

On one of the main lines of the system in a city which is, perhaps, more completely equipped with trolleys than any other—at least in the number of miles of tracks, which occupy nearly every street—there are two motormen, one of whom usually follows immediately after the other, but they do not always have the same cars; yet, constant riders on the road have learned by experience that a car operated by one of the motormen always glides along, in winter or summer, so smoothly that the skimming motion is positively pleasurable, while a car operated by the other motorman often reminds one in its actions of the famous "Swedish Movement Cure Apparatus." From daily observation of these facts it would appear that the difference in behavior of the cars, operated by the same electric force, is due to the difference in degree of skill of the motormen; in other words, the "personal equation" is a more important factor in the manipulation of these modern conveyances than is generally supposed. A well-known mechanical engineer has stated that the increased wear and tear upon the rolling stock, due to sudden and often needless application of brakes, and the waste of electrical energy by unskilled or nervous motormen, sometimes equals, if it does not exceed, the amount of wages paid to the skilled man.

By the aid of a little "inertia indicator," which may be carried in the pocket and rested on the window-sill of a

car, some interesting tests have been quietly made during the past few months without the knowledge of the motormen—or even of the company—which will go far to substantiate these statements when they shall have been compiled into tabular form.

It is a remarkable fact that in almost all large business corporations there appears to be a certain lack of close attention to small details such as this, and it has often happened, therefore, that economies and improvements which should naturally have suggested themselves to those most familiar with the business, have come from outsiders whose very unfamiliarity with the details seems to aid them, in that they are apparently more observant of such minor defects. As an illustration, a single case may be mentioned here.

Some time ago a daily commuter on a suburban steam railroad wrote a somewhat humorous communication to a newspaper calling attention to the annoyance caused to passengers by the constant slamming of the car doors by conductors and brakemen in cold weather. Nearly two years before that time he had expressed the same views politely in a communication to the proper official of the company without any notice having been taken thereof. Recently, however, several of the cars on this road have been equipped with silent air-cushion springs on the doors to the great delight of the passengers.

The conclusion to which this somewhat discursive note points is, that it would, doubtless, pay every large corporation catering to public patronage to employ some person (perhaps a bright woman) simply to examine into these "little things" and to see that every practicable improvement looking to the comfort and convenience of the patrons should be adopted. It is, in fact, largely owing to the introduction of many such little conveniences for shoppers that the modern department store owes its great financial success. A. E. O.

Electrical Resistance of Rails

Kioto Traction Company,
Kioto, Japan, Jan. 16, 1899.

Editors Street Railway Journal:

Your December issue contains a paper by Mr. A. B. Herrick on "Some Fallacies Regarding Electrolysis," which I have carefully read over with great interest.

In this paper he has tabulated some electrical resistances of different iron pipes and rails, of which those of rails are very useful to me, as well as to those who use their track as return circuit. However, I have noticed that his resistances of rails are greatly at variance with those which I have calculated to show a fair average.

I mention here my results in ohm per 1000 ft.

A 45. lb. rail	0.01104	ohm and single track of			45. lb. rails	0.00552	ohm
A 50. lb. rail	0.00993	"	"	"	50. lb. rails	0.00497	"
A 60. lb. rail	0.00828	"	"	"	60. lb. rails	0.00414	"
A 70. lb. rail	0.00709	"	"	"	70. lb. rails	0.00355	"
A 80. lb. rail	0.00621	"	"	"	80. lb. rails	0.00311	"
A 90. lb. rail	0.00552	"	"	"	90. lb. rails	0.00276	"

Mr. Herrick's resistance of single rail somewhat resembles that of corresponding single track, calculated by me, or, in other words, his resistance is only a half of mine.

When, several years ago, Mr. J. H. Vail read a paper on "The Importance of Complete Metallic Circuit for Electric Railways" before the National Electric Light Association (see the Street Railway Journal for March, 1894), he gave the following table:

	56 POUND RAIL.		70 POUND RAIL.	
	One Rail.	Single Track of Two Rails.	One Rail.	Single Track of Two Rails.
Area in sq. inches	5.4874	10.9748	6.8593	13.7186
Equal in area to circle whose diameter is in inches	2.642	3.735	2.95	5.90
Equivalent in cir. mils to	6,980,000	13,960,000	8,702,500	17,405,000
Resistance per foot B. A. units	.00000845	.00000422	.00000679	.00000339
Equivalent to copper resistance in cir. mils	1,175,000	2,350,000	1,463,000	2,926,000
Equivalent to copper rod whose diameter is	1.13	1.533	1.21	1.71
Safe carrying capacity of iron reckoned at ⅓ that of copper in amperes	390	780	488	976

NOTE.—In the above statement the areas of rails have been determined by use of the planimeter. The ampere capacity of iron has been based upon the most reliable data obtainable. The resistance of iron is taken as 5.63 times that of copper.

This table coincides quite closely with my results. These differences, though of only minor importance to the subject of Mr. Herrick's paper, are never negligible when investigating track resistance and conditions of rail bond, etc. I should like to hear from him as to how he got his results and to learn whose figures are the most reliable.

Ichiro Goto, E. E.

Mr. Herrick's Reply

The following is Mr. Herrick's reply to this letter:

New York, March 25, 1899.

Editors Street Railway Journal:

In answer to Mr. Ichiro Goto's communication I have to thank him for calling my attention to the omission made in transcribing this table. The resistances given are for 1000 ft. of single track, so for single rail resistance the value would have to be one-half that given. There are a great many values given for rail resistances, but no observers have as yet considered the element of temperature. A good steel rail has a temperature coefficient of about 0.48 per cent for each degree of centigrade rise.

The following values have been given for 90-lb. single rail for 1000 ft. in ohms:

Bell	.00666
Goto	.00552
McTigh	.00660
Vail	.00528
Herrick	.00521

The composition of the rail plays a very important part in this resistance. Generally speaking, an increase in carbon is accompanied by an increase in electrical resistance, but by a decrease in the temperature coefficient.

Albert B. Herrick.

Repair Records in Chicago

In June, 1897, G. W. Knox, electrical engineer of the Chicago City Railway Company, instituted a system for carefully checking and recording all cases of trouble with the electrical equipment on the cars of the road with which he is connected. The records of these electrical troubles are sent in by the conductors and motormen on whose cars the breakdowns occur, and Mr. Knox carefully investigates and verifies these reports by consultation with the barn foreman and repair men. The records are kept separately for each car house, of which there are four, and the electrical engineer is thus able to tell not only the different kinds of troubles that occur and the most common ones, but is also able to tell the relative efficiency of the different car houses in keeping their equipments in good repair. The following tables contain the records for the entire system only, and not for the different barns separately.

In Table No. 1 is shown the total number of each kind

of trouble with electrical equipments reported for the year ending Dec. 31, 1898, and also the percentage of each kind of complaint to the total number of all complaints reported:

Table No. 1—Repairs to Electrical Equipments.

	Total Number Cases Reported.	Per Cent Each Kind Repairs to Total Electrical Equipm't Repairs.
Repairs to Armatures	217	24.6
" Controllers	50	5.7
" Lights	24	2.7
" Wires	119	13.5
" Brush Holders	196	22.2
" Rheostats	12	1.4
" Miscellaneous	40	4.6
" Trolleys	193	21.9
" Fields	27	3.1
" Lightning Arresters	3	.3
Total Repairs to Car Equipments	881	100.0

Average number of cars operated 351.9.

Table No. II—Armature Repairs.

Nature of Repair.	Type A.		Type B.		Type C.		Type D.		Total Each Kind Armature Repairs.	Per Cent Each Kind Armature Repairs to Total Armature Repairs.

Number of years motors have been in use	6	2½	4	3	....
H.p. of motors	25	25	30	25	....

New Construction in New Orleans

The New Orleans & Carrollton Railroad Company, which has recently purchased all the property and franchises of the Canal & Claiborne Railroad Company, is contemplating some important extensions to its system, including not only additions to its power stations, but also to its mileage and rolling stock. During the last month this company has placed, through its engineers, Mesrs. Ford, Bacon & Davis, orders for sixty G. E. 1000 double-motor equipments, an 850-kw. General Electric generator, a 1275-h.p. Allis-Corliss cross compound condensing engine with Allis condenser, and track and special work for 15 miles of track. The latter will probably be the heaviest T-rail construction ever laid for electric railway service.

The rail, which is of the A. S. C. E. section, 5¾ ins. high, will weigh 100 lbs. to the yard, and will be supplied by the Pennsylvania Steel Company, in 60-ft. lengths. A departure from usual New Orleans practice will be made in this track construction, which will consist of creosoted-plank flooring, supporting crushed stone ballast, upon which will be laid the 100-lb. rails on 6 in. x 8 in. x 8 ft. creosoted ties. The T rail special work will be supplied by the Pennsylvania Steel Company, and the girder rail special work by the Lorain Steel Company.

This company is about to order sixty new cars and 1000 h.p. of boilers. The generating apparatus will be installed in the Claiborne power station, and a double-track extension will be laid to connect the terminus of the Tulane avenue line with the terminus of the Carrollton line, thus making a loop or belt line between the two systems back of the city.

New Association in Virginia

A State association of prominent street railway and electrical men was recently formed in Virginia, and will be known as the Virginia Street Railway & Electrical Association. Its avowed object is the acquisition of experimental, statistical and scientific knowledge relating to the construction, equipment and operation of street railways and electric plants, and the diffusion of this knowledge among the members of the association, with a view to promoting the street railway and electric interests, improving the service and reducing its cost; the establishment of a spirit of fraternity among the members of the association by social intercourse, and the encouragement of cordial and friendly relations between its members and the public. The constitution provides for an associate membership consisting of manufacturers and dealers in street railway and electrical supplies, engineers and contractors, etc. The officers of the association are: President, R. D. Apperson, Staunton; vice-president, E. R. Williams, Richmond; secretary and treasurer, H. P. Woodson, Lynchburg; executive committee, R. D. Apperson, Staunton; R. L. Williams, Norfolk; D. W. Flickwir, Roanoke; H. P. Woodson, Lynchburg; E. R. Williams, Richmond. The next meeting of the association will be held at Richmond May 16, 1899.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL, *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Havemeyer Building, 26 Cortlandt St., New York.

Notice of Removal

On April 15 the offices of the Street Railway Publishing Company will be moved from 26 Cortlandt Street to 120 LIBERTY STREET, New York. Our new offices occupy half of the eleventh floor of the Beard Building, which is in the center of the "Electrical District" of lower New York city, and is very conveniently located as regards the Sixth and Ninth Avenue elevated lines, the surface railways and all the North River ferries. As in the past, we shall be glad to have our subscribers and friends use our office as their headquarters during any visit to New York. Remember the new address, 120 LIBERTY ST.

The "automobile" has, almost in a day, emerged from comparative obscurity to a position of the utmost importance in the world of transportation. Until the past year, far more interest has been taken in automobile work abroad than in America, but now "operations," both in stocks and in physical accomplishments, are on the largest scale. Electric vehicle companies and compressed air "autotruck" companies, parent and territorial, have been formed in New York and several of the principal American cities, and capital is rushing into these new fields with ardor and enthusiasm. Disappointments may be in store for over-sanguine investors, but at the foundation of the automobile industry lies the indisputable fact that the horse power thus sought to be displaced is intrinsically costly to a degree such that almost any form of mechanical motive power, even if not theoretically high in efficiency, should show an advantage over horses warranting initial and subsequent expenditures for experimentation. In other words, it is quite probable that the pioneers in this industry will make enough money, even with imperfect apparatus in original installations, to purchase the new and better equipment of later days with further profit.

The possibilities of automobile work, particularly in the line of cabs, omnibuses, carriages, etc., should be regarded by street railway managers with close attention, if not with concern. Electric cabs in New York have become instantly popular and are in constant and pressing demand, the supply being so far totally inadequate for the requirements. Electric cabs will do double the daily mileage of horse cabs. They are under perfect control, running smoothly and silently through the streets, and weaving in and out among vehicles far more easily and with greater saving of time in blockades than can be done where horses are used, and it has been proven possible to equip these cabs with batteries small in compass, but powerful enough to propel the cab for from 20 to 25 miles. Fresh batteries can be placed in cabs within three or four minutes, and a new lease of life secured. Finally, the assumed advantage of electricity over horses has been, as usual, divided between the operator and the public, so that the public is getting a service far superior to the old and at a lower price. What has not been so far demonstrated, however, is the actual amount of this advantage over horses. No figures have yet been given out as to operating expenses of the cab service, and in the nature of things, some elements of these expenses cannot be known for a year or two to come. Depreciation of the batteries is one of these uncertain elements of expense, and the cost of maintaining the heavy and expensive pneumatic tires is another. But, all drawbacks and uncertainties aside, it seems probable enough that initial difficulties will be overcome and the industry will develop into a profitable one. Street railway companies will do well to investigate the financial opportunities afforded by a local electric cab service with a view to making such a service a part of a complete city transportation system under their control. One of the principal advantages of this action would be found in the possibility of greatly increasing the load factor of street railway power stations by operating them at their full capacity during the lighter hours of the day, using the surplus power for charging batteries for the cab system. By this means the cost of electric power per kw.-hour output can be greatly reduced, while a transportation profit far exceeding the power profit ought also to be possible.

The economical distribution of railway current over long distances can be effected by boosters, accumulators, or the use of polyphase apparatus, and with the increase in the number of long distance lines the question of determining which of the three methods is the most economical, under a given set of conditions, is an important one. Elsewhere in this issue a careful summary of the relative advantages of continuous current distribution from a number of separate stations and that of alternating current distribution from one central station is carefully considered by Mr. Parshall. The particular system studied is that of the city of Glasgow, but the same principles can be applied, with certain important modifications, to properties elsewhere. The relative cost of installation and maintenance is carefully considered, but the problem in Glasgow, as will be seen from Mr. Parshall's treatment of the subject, was largely affected by the determination to keep the potential drop on the return circuit within a maximum of $3\frac{1}{2}$ volts, or one-half that allowed by the British Board of Trade. This restricted the distribution from any one station to a maximum of $\frac{1}{2}$-mile radius, and as this limitation does not exist in the United States, and as the cost of labor and apparatus is somewhat different, the conclusion reached by Mr. Parshall would not apply directly to installations in America. In an article by another writer in this issue, the relative advantages of motor dynamos or accumulators is considered, from the standpoint of efficiency. The writer assumes the use of both methods of boosting under similar conditions, and then draws a comparison between the relative first cost and operating charges of the rotating booster and the accumulator booster. The increasing use of accumulators shows, however, that relative efficiency is not the only criterion for judging this problem, but that the effect of the battery in increasing the load factor, thus reducing the necessary station capacity for a given load, is a most important consideration. It will be remembered that an increase in the load factor with the same output not only reduces the first cost of installation, but also raises the mechanical efficiency of the station by making the load more steady, and thus rendering it possible to operate the engines more continuously at the point of maximum economy. In this connection we might say that the relative efficiency of station apparatus, operating under different load factors, with the highly varying momentary fluctuating loads which exist in electric railway stations, has never been so thoroughly discussed as many of the other problems in electric railroading. We hope in an early issue of the Journal to publish some statistics on this subject, taken from actual practice, and think that they will throw considerable light upon the subject of the possible economy of railway power stations.

The selection of schedules for high speed city transportation service is not, and should never be a mere matter of guess work, or be regarded as one of the incidental problems. It is, on the contrary, *the one great problem of the installation,* in comparison with which all others, including those of the details of the electrical equipment, are entirely subordinate. In order to operate any given property at a given frequency and a given schedule speed, a certain investment is required and certain operating expenses will be incurred. In a given range of possible schedule speeds, as, for example, 10 miles to 20 miles per hour, there will be maximum and minimum investments and maximum and minimum operating charges. The most careful detailed estimates, covering both investment and operation, should be made by trained engineers specially delegated for this work, and from their calculations when presented to the managers should be selected the schedules best adapted for the traffic conditions. Without such investigation, the electrical equipment of a high speed transportation line is a leap in the dark, and if as a result of insufficient study of the problem presented, a schedule speed be selected lower than what is economically possible to obtain, the disaster is private as well as public, and is likely to be accompanied with the most serious consequences in the matter of profits, particularly if a shrewd and far sighted competition exists, able to take advantage of all mistakes.

The New York Rapid Transit Proposition

The citizens of New York have reason to regard with almost complete satisfaction the proposition just made to the Rapid Transit Commission (given in full on page 230 of this issue) by counsel representing the Metropolitan Street Railway interests. For nearly a decade the problem of rapid transit in New York has engaged the close and anxious attention of the many able citizens on the commission, but their efforts have until now been fruitless, owing to causes more or less beyond their control, and New Yorkers had almost come to despair of any tangible results to their labors.

In the letter transmitting this proposition to the Rapid Transit Board, it is clearly pointed out that the reason why capital has not hitherto responded to the long continued invitation of the city to take the risk of constructing an underground road, is that there is not sufficient probability that such a road could be profitably operated without surface collecting and distributing facilities. These facilities the Metropolitan Street Railway Company alone has, and is therefore enabled to make a proposition which cannot be duplicated by any other transportation agency, or by individual capital. It is also made clear that the real obstacle to rapid transit lies in the congested district in the lower part of the city, and by localizing traffic in the streets of this district and putting all through or longer-distance business into the tunnel, the streets may be relieved of much of their burden, and better transit even on the surface may be secured.

It is hard to speak of a plan of this broad and far reaching character without enthusiasm. The "Metropolitan Syndicate" has given to the people of New York, in the last few years, many evidences of largeness of conception, breadth of view and generosity of action—qualities which, when found in any group of individuals dealing with questions of intense public interest, always bring about the greatest possible benefits to a community. This new proof of the ability and acumen with which transportation matters can be handled by those who understand thoroughly the financial and operating possibilities, is now superadded to the old. Who, in noting the halting and irresolute way in which such problems are dealt with in other cities of the world, can say that New York is not indeed fortunate

in having in its service private capital which, while always and necessarily seeking profits for itself, has, at the same time, so broad and generous a confidence that the people will respond almost immediately to the increase and perfection of transportation facilities, as to warrant enormous present outlays, upon which the more or less remote future must be called upon for dividends?

From an operating standpoint, the keynote of the entire plan lies in the specification of a ten-cent fare for express service, and from the public standpoint, the justice and wisdom of granting this concession cannot be for a moment denied, for not only are the express trains, as defined in the proposition, to be run at schedule speeds of from 20 to 30 miles an hour, which is extremely costly work, but it will always be within the option of the intending passenger to choose a five-cent fare ride over the same distance as that covered by express trains, and at an average speed which will doubtless be at least one-third greater than are the present Manhattan schedules. Moreover, the total traffic will be better distributed between express and local trains than is the case on the New York elevated roads at present, since those who can better afford to pay the higher price for "first-class" service may do so and leave better accommodations in the local trains for those who must use the latter perforce; and finally, the express train passenger has the privilege of using the surface cars, without additional charge, for reaching his very door.

It is now a part of the settled policy of the State of New York as expressed by general legislation to grant street railway franchises for twenty-five years only. It is obviously impossible to impose any such conditions upon an enormously costly enterprise of this character, and we feel that inasmuch as the Metropolitan Street Railway franchises are in themselves practically perpetual, having been granted many years ago before the passage of the general legislation just referred to, and inasmuch as almost the entire value of the proposition depends upon the surface connections with the Metropolitan Street Railway Company, the demand on the part of the latter for a perpetual franchise is not unwarranted, and will be favored even by those who are ordinarily opposed on principle to grants of this general character. The *quid pro quo* offered to the city is worth some sacrifice to obtain, and no alternative offer of equal advantage from other parties is a possibility. New York has sighed for rapid transit through so many years, that now when it is actually within reach on an equitable basis, it is inconceivable that it should be rejected on more or less theoretical grounds.

One other feature of the proposition, that of securing to the tunnel company and its lessees the right to use and lease what are practically subway rights, has excited comment and a little adverse criticism on the part of the press. It would be absurd to refuse this right, however, not only because by placing pipes, wires, etc., in a tunnel of this character, the best interests of the city are served; not only because the transportation profits, pure and simple, are problematical, as has been shown by the reluctance of capital to make to the city any proposition for the building of such a tunnel line, and therefore collateral profits should be permitted when not interfering with the city's best interests; but also because the financial interests which are making this rapid transit proposition to the city are owners of practically all the high tension subway rights so far given in the city, and have presumably a further right to construct new subways irrespective of that to be conferred upon the tunnel company.

The many complicated and important engineering problems which will be raised in this new transportation in New York city will be of widespread interest to the engineering public. The press of New York has done no more than justice in saying of the management of the Metropolitan Street Railway Company that the general public knows how well and quickly it carries through its work, and the fact that, doubtless after most careful estimates by its engineers, it is proposed to complete the four-track tunnel south of 104th Street, together with the three-track west side branch north of that street, in thirty-six months from the time that the franchises are perfected, is a commentary upon the possibilities which lie in thorough organization for the accomplishment of a given end. It is evident that there will be work in New York city for all who want it within the next few years.

The new rapid transit plans for New York city leave the present elevated railway system in a peculiar position. Hitherto its principal claim upon traffic has been its ability to carry passengers over the longer distances in the city with a decided time saving. Now its aggressive rival, the Metropolitan Street Railway Company, proposes to enter into competition with it for this class of traffic on a basis which can hardly fail to be effective. It cannot hope to run express trains on its elevated structure as rapidly as the underground express trains, it cannot hope to run its local trains faster than the underground locals, and it will have no collecting or distributing agencies on the surface unless it should acquire, or be acquired by the Third Avenue Railroad Company. It will still carry passengers, and many millions of them, and it still has its future destiny measurably within its own hands, though within far narrower limitations than ever before, but consummate wisdom and ability and a complete change of attitude toward the public will be necessary if even moderate financial success is to be attained. It has as competitors those who believe that more money is to be earned by increasing gross receipts than by reducing operating expenses, and to this end the best possible service of the public is none too good. If, as has been reported, it is not the intention of the Manhattan Company to greatly increase its present schedule speeds when electricity is adopted, but to depend more upon making a saving in operating expenses upon but slightly faster schedules, the Manhattan Company is out of the race and will remain so. If, on the contrary, it will wisely determine to give to the people of New York an elevated railway service such as has never before been seen in any city, there is some chance that a large proportion of the city travelers will prefer a ride in the air to the "hole in the ground."

Announcement was made last month of the incorporation at Trenton of the Consolidated Street Car Company with a capital of $18,000,000. It is said to be the combination of a number of the principal builders of street cars in the United States, and seems to be a confirmation of the rumors, which have been persistent during the last few months, that several of the builders of street railway cars were contemplating a general consolidation. The names of the companies whose properties will be acquired by the new corporation have not yet been made public.

Gross Receipts Per Capita and Per Mile of Track in the Principal American Cities

The accompanying table has been carefully compiled, with a view to showing the comparative patronage by the peoples of the principal cities of the United States of their street railway systems. The table covers the population served, the miles of track, the gross receipts, the gross receipts per mile of track, and the gross receipts per capita served.

NAME OF CITY.	Street Railway Systems. Population Served.	Number Included.	Miles of Track.	Gross Receipts.	Gross Receipts Per Mile Track	Gross Receipts Per Capita.
New York City—						
Manhattan and Bronx.				$	$	$
Elevated Lines	2,156,000	1	109	9,183,542	84,252	4.26
Surface Lines		8	368	16,044,332	43,597	7.44
Total		9	477	25,227,874	52,910	11.70
Brooklyn.						
Elevated Lines *f*	1,197,000	3	75	2,481,730	33,090	2.07

a Including suburbs reached by street railway lines whose gross receipts are given. *b* Estimated. *c* Principal system. *d* Population partly estimated. *e* Comprising populations of twenty-one cities and towns tributary to the cities of Lynn and Boston. *f* Including receipts, mileage, etc., of New York and Brooklyn Bridge.

It is most difficult to obtain reliable figures of the population between census years, and the accuracy of those found in this table is by no means guaranteed. They are, in most instances, given on the authority of the Mayors of the different cities, and are usually based on some form of local census taken for police, school, or taxation purposes. Judging from past experiences, however, it is more than probable that next year's national census will show that these estimates are somewhat too high in many, if not in most instances. They are, however, the best figures obtainable at the moment.

Where a city street railway system can be isolated from its suburban connections, the population of the city alone and the mileage and receipts of the city system are given. In many cases, however, city lines operate in the suburbs also, and wherever this occurs the population of the suburban cities and townships connected by street railway lines with the principal city, together with the mileage and receipts of all suburban lines distinct from the central system, are also included. The number of street railway systems included in the group of cities is given in the third column.

"Miles of track" means total track mileage, counting one mile of double track as two of single, and including sidings, turnouts, etc.

"Gross receipts" means in nearly every instance receipts from passengers only, but occasionally it has been found impossible to separate the passenger receipts from the receipts from operation, which are slightly greater than the passenger receipts.

As street railway mileage and receipts are both theoretically functions of population, the cities and groups contained in this table have been arranged in the order of their population, the largest city of all, New York, being first in the list. By this means the peculiarities and apparent inconsistencies of the statistical results are quite clearly brought out ready for explanation.

The largest gross receipts per capita are obtained by the street railway systems in the following cities and groups:

	Population.	Gross receipts per capita.
San Francisco	350,000	$13.83
New York (Manhattan and Bronx)	2,156,000	11.70
Boston (and immediate suburbs)	788,000	11.56
Greater New York	3,546,000	10.44
Eastern Massachusetts	1,250,000	9.86
Kansas City (principal system)	200,000	9.72
Philadelphia	1,197,000	9.19
New York (Brooklyn Borough)	1,250,000	9.16
St. Louis	675,000	8.65
Pittsburg-Allegheny	528,000	8.24
Eastern New Jersey	603,000	8.07
Chicago	1,875,000	8.06

The largest gross receipts per mile of track are shown by the systems in the following cities and groups:

New York (Manhattan and the Bronx)	$52,910
New York (complete)	33,199
Boston	26,091
Philadelphia	23,663
New York (Brooklyn Borough)	22,597
St. Louis	19,324
San Francisco	17,733
Montreal	15,792
Eastern New Jersey	10,216

Strange to say, New York city, though by far the largest in the country, does not lead the list in point of gross receipts per capita, but this honor is reserved for San Francisco, which shows $13.83 percapita, as against $10.14 for Manhattan and the Bronx. On investigation it is seen that San Francisco has a very heavy density of traffic as compared with other cities of about the same size, but has a much greater mileage in proportion to its population than has New York. It is evident that the people of San Francisco are liberal in their patron-

age of the street railway system, and it is also a fact that while the traffic density in Greater New York is very large, there are immense areas of comparatively unsettled territory still to be served by street railways, and in spite of the great traffic density on the existing lines ($33,199 per mile of track), especially in the boroughs of Manhattan and the Bronx ($52,910 per mile of track), much more mileage is needed in Greater New York, and the city transportation systems are destined to show much larger gross receipts per capita.

In the boroughs of Manhattan and the Bronx, New York city, the elevated lines obtained (during the year ending June 30, 1898,) 35.4 per cent of the total traffic, leaving the remainder to the surface lines; in the same financial year the elevated lines of Brooklyn carried but 22.5 per cent of the total traffic. In both instances the returns for the present year now being made will doubtless show a considerable diminution of the percentage obtained by the elevated railways, with increasing competition from the surface lines. In Chicago the elevated lines are obtaining 31.5 per cent of the total traffic, a decidedly good result considering the different conditions under which they are working.

The seventy cities and towns of the "Eastern Massachusetts group" are earning as a whole $9.86 per capita, an extremely large figure considering the extent of territory covered and the excellent service given by competing steam railway suburban lines in this territory. It will be seen, however, by comparing the figures of this group with those of Philadelphia, which has a population almost exactly equaling that of "Eastern Massachusetts," that these large gross receipts per capita are due to the immense mileage in the area, and not to density of traffic on that mileage, the results per mile of track being for "Eastern Massachusetts" but $13,793, as against $23,663 in Philadelphia, and the track mileage being nearly double that of Philadelphia. It is almost equally remarkable that metropolitan Boston, which includes the city proper and about a dozen cities and towns immediately surrounding it, should have larger gross receipts per capita than Philadelphia, but as a matter of fact the territory contained within Philadelphia city limits is not greatly different in character from that of Boston suburbs, except that there are no such large population centers in the former as are found, for example, in Cambridge, Somerville, etc., in the latter.

The great manufacturing district which contains Pittsburgh, Allegheny and many small townships, has almost exactly the same population as is found in Cleveland and suburbs, but the character of the district is far different, nearly all the manufacturing interests being in and about the city proper of Cleveland, while in the Pittsburgh district they are scattered over the entire area of the group. The Cleveland suburbs are largely residential in character, and are situated at considerable distances from the city. For these reasons it is not surprising that in the Pittsburgh district the street railways should earn $8.24, as against $6.51 in the Cleveland district. San Francisco, New Orleans, Washington and Denver are earning considerably more per capita than Detroit, Milwaukee, Providence, Louisville, Montreal, Indianapolis and Rochester, cities of approximately equivalent sizes. Some of the reasons why San Francisco shows its remarkable earnings have already been given; another is the conformation of the city, which is peninsular in character, with the business district at one end of the peninsula and the residential and pleasuring sections far removed therefrom. Toledo stands out among nearly all the cities of its size as having large receipts per capita, but its receipts per mile of track are not extraordinary.

The effects of overbuilding of track are seen in the low receipts per mile found in Detroit, Rochester, Syracuse and Atlanta, and the smallest receipts per capita in the entire list are obtained by the street railway systems of Fall River, Scranton and Syracuse.

Rapid Transit in Dense Centers of Population

BY JOHN LUNDIE

The following important maxim has been well borne out by repeated experience—"Increase of good transportation facilities will carry with it its own traffic in a populous district."

An instance of the truth of this maxim might readily be appreciated by a study of the suburban traffic of the Illinois Central Railroad Company at Chicago. The southern part of the city of Chicago has within recent years been practically honeycombed by electric street car lines. In addition, the South Side Elevated Railroad has also been an important factor in seeking South Side traffic. Both the street car lines serving the territory near Lake Michigan and the elevated road have given remarkably good service, and as a result have obtained a traffic commensurate therewith. Notwithstanding, however, this apparent inroad on territory served by the Illinois Central Railroad, the suburban traffic of this road has continued to show a healthy increase. The reason for this has been that the management of the road has been alive to the exigencies of the situation, and has given a service at all times second to none. This by way of illustration of the above maxim.

In contrast to development of traffic by increase of good transportation facilities there could readily be pointed out numerous instances of loss in traffic by transportation companies through neglecting to recognize the needs, if not the rights, of the traveling public, by the short-sighted policy of restricting transportation facilities on the slightest indication of traffic being diverted to other channels, intending thereby to reduce expense so as to make a good financial showing in spite of the reduction of traffic.

Transportation service and traffic are mutually interdependent. Primarily, a service ought to be suited to a known or expected traffic, and thereafter the service ought to be conducted in such a manner as to seek and hold the appreciation of its patrons. Then the traffic will react on the service, and will justify its continued improvement by healthy increase.

Short-haul and long-haul traffic are only comparative terms; but whether the terms be applied to traffic on a trunk line or to that within the comparatively short distances covered by rapid transit lines in or near a great city, the principles governing the handling of short and long-haul traffic remain practically the same. Passenger traffic in a great city naturally follows the lines of least resistance. Thus, a passenger going only a short distance will almost invariably prefer even a comparatively slow, frequent street car service to that of an elevated road. Reluctance to undertaking the effort of climbing an elevated railroad stair, or the effort involved in consulting a timetable and waiting for a train, readily explain why short-haul traffic naturally becomes tributary to street car systems, even though private right of way systems may seem equally convenient.

From the standpoint of a transportation company the value of a service is its ultimate net revenue. This, however, is wholly dependent on the traffic which it is able to secure from the traveling public.

From the standpoint of the traveling public the induce-

ment to use any service is dependent, primarily, upon four principal conditions, viz.—*fare, frequency, comfort* and *speed*.

Comparing, for example, the street car lines and the elevated lines in New York City, it is at once noted that they have corresponding elements of fare and frequency. The element of comfort (which is an important one) might be said to be in favor of the elevated, but this is offset by the objection to stair climbing. Thus, it would appear that the elevated service has no advantage whatever over the street car service in the elements of fare, frequency, or comfort; so that there remains only the element of speed in its favor. Unfortunately, especially at times of heaviest travel—morning and evening—the speed of the elevated trains is so reduced as to tell severely against patronage which would otherwise belong to the service without question.

Were there only a few distinct centers of traffic distribution within the territory served by the elevated roads in New York City, so-called "express" service might secure and retain long-haul traffic. The centers of distribution, however, are practically scattered along the whole lengths of the lines.

"Express service" is only a relative term. As a matter of fact, all elevated service might be designated as "express" when compared with that of street cars. Stations on such lines are, or become, centers of distribution, and if the traveling public is distributed along a given length of the line with fair uniformity, the mistake must not be made of cutting out frequent stops without due justification; otherwise, the street car service will attract an undue proportion of longer haul traffic on the principle of its being the direction of the least effort to the passenger.

In seeking an advanced solution of the rapid transit problem in New York, it is to be feared that the question of competition between transportation companies is apt to unduly govern progress. The maxim before quoted as to "increase of good transportation facilities carrying with it its own traffic in a populous district" would be found to be a more certain guide to success in considering the interests of both the transportation companies and the public, than by simply watching "the other fellow" and trying to do just a little better than he is doing.

Street car service and high speed service ought to be complementary instead of antagonistic, and whether the lines are owned by different corporations or by the same, there ought to be but one policy, viz., that of offering unquestioned transportation facilities on both classes of service. It being understood that elevated or similar service is essentially for the handling of comparatively long-haul traffic, such service to be successful must cater to the appreciation of its patrons. It may be said broadly that the only excuse for the existence of an elevated structure is the possibilities which it presents for high speed. Such possibilities do not exist with street cars. It is thus apparent that speed is the one prerogative of the elevated lines, or of lines having a private right of way, and it is by virtue of this element of speed that such services may expect to retain or increase the traffic naturally tributary to them.

Rapid transit is the most important element in the building up of a residence territory comparatively remote from a business center. Were the owners of property in an outlying district the owners of a railroad they could not afford to do otherwise than adopt the highest practicable rate of speed on the line, as, by so doing, the values of property would be thereby increased, approximately in proportion to the speed, seeing that outlying points would thus be virtually brought just so much nearer to the business center.

There is naturally a physical limit to the speed which can be made over any line, with given station distances, gradients, curvature, or other restrictions to free running, whether such restrictions be natural or arbitrary. A change of motive power is not by any means *per se* a panacea for the loss of traffic by express lines of transportation which have lost the right to the term express, unless such change of motive power should conduce to improved service. Thus, to operate elevated lines electrically on the schedule rates of running existing with steam operation might be rather an apparent than a real economy, and might readily illustrate the remark heretofore made as to attempting to recoup lost traffic by reduction in expense, instead of by improvement of the service. Operation electrically, after the novelty of the thing had worn off, could not of itself be expected to increase traffic. Speed is the one element of paramount importance which should place the express lines where they ought to stand, as most important factors in the necessary transportation facilities radiating around a great center of population.

In seeking to reach a decision as to motive power a consideration of variations in speed is all-important The expression "schedule speed" is apt to be rather confusing, unless the points between which the run referred to is made are stated. In considering the subject of variation in speeds it is well to bear in mind some simple definitions, which, while seemingly perfectly understood, are sometimes confused one with another.

Schedule speed may be defined as the average rate of running between any two points, obtained by dividing the total distance by the difference in time between that of starting from one point and that of arriving at the other, inclusive of all intermediate stops.

Average running speed is, of course, somewhat higher than schedule speed, and is obtained by dividing the total distance by the difference in time between that of starting from one point and that of arriving at the other, deducting the time consumed in all station stops.

Maximum speed is the greatest speed attained between any two successive stops, and for the same average running speed may vary within very wide limits.

The two extremes in performing any given average running speed are—

1. Accelerating up to the point of braking.

2. Accelerating as rapidly as possible to something above the average speed, and then either coasting, or practically holding this speed to the point of braking.

In the first case it is evident that the maximum speed must be very much higher than that in the second case, in order that the total distance may be covered in the same time. Thus, it is necessary to make a careful study of variations in speed in the performance of any given schedule, as on such variations depend—

(*a*) The necessary weight on the driving wheels required to give sufficient adhesion for acceleration.

(*b*) The power and capacity of the necessary motor equipments.

(*c*) The total energy to perform the movement.

In the case of the first method mentioned, viz., accelerating up to the point of braking, in making a given distance in a given time, the least powerful motors are required, but, on the other hand, the maximum amount of energy is used in performing the service.

In the case of the second method, viz., accelerating as rapidly as possible to something above the average speed, and then either coasting or practically holding this speed to the point of braking, the most powerful motors are required, but the minimum amount of energy is used. Thus, the consideration of the advisable acceleration to be given to trains in performing a given service is

governed, in a great measure, on the one hand by the capacity of motor equipments required to perform the service, which increases as the acceleration becomes greater; and, on the other hand, by the amount of energy required to make the run, which increases as the acceleration becomes less.

The first cost and subsequent operating expense of motors and power stations are not, however, the only factors of expense which vary with speed and method of train movement. For a given starting schedule on any line, *i. e.*, for given train intervals and given numbers of cars per train, the net car mileage on the line will simply be the total number of cars started multiplied by the length of the round trip. This is independent altogether of the speed which the trains make, as the number of cars passing a given point in a given time remains constant. As the speed is increased the same train schedule can be performed with a smaller number of cars; and while the car mileage remains the same the net car hours (being the net car mileage divided by the schedule speed) will vary inversely as the schedule speed.

As the wages of motormen and trainmen are practically on a time basis, it is evident that as the speed is increased these elements of cost of train operation will diminish in inverse proportion. This also is true with such elements as train lighting and heating. Cost of regulation and other matters also require careful consideration.

It will thus be seen that in order to reach a satisfactory decision as to improved service along modern lines, there are many elements to be considered, even before that of so-called motive power itself is taken up, and, in fact, the purely electrical engineering problems involved in a change of motive power are but one element in the economics of train movement calculated to serve given or prospective traffic requirements.

The management of any transportation enterprise of this character will naturally ask the following questions:

What object is to be attained by making a change in transportation methods?

What is to be the influence on revenue by making changes in a service?

What are such changes going to cost for varying conditions of service?

What is it going to cost to operate under the varying conditions of service suggested?

Satisfactory answers to these questions will involve a full knowledge of the whole range of possibilities of high speed operation. With this information before those whose money is to be spent, a decision can readily be reached as to advisable changes from a politic or an economic standpoint. On the other hand, the mere assumption that electric operation of a service, however applied, will solve the rapid transit problem, might, if carried out under certain conditions, be wofully disappointing.

The New York City Rapid Transit Proposition of the Metropolitan Street Railway Company

For several years past the Board of Rapid Transit Railroad Commissioners appointed by the Governor of the State of New York to consider the burning question of rapid transit on Manhattan Island have labored faithfully, though without result, for the accomplishment of the purpose for which the board was created. Their last proposition was that the city of New York should itself construct a tunnel and lease the right to operate it to private capital for a term of years, by which means it was hoped that through the city's excellent credit the fixed charges might be kept at a minimum. This proposition failing, others were made to the Manhattan Railway Company, looking to the extension and increase of facilities of the elevated railway system, but the Manhattan Company refused to accept the plans and suggestions of the commission, and again failure was met.

On March 27 the Rapid Transit Commissioners received from the counsel of the syndicate which owns a controlling interest in the Metropolitan Street Railway Company the following remarkable proposition:

To the Board of Rapid Transit Railroad Commissioners:

Gentlemen—We are authorized to make the following proposal in behalf of clients interested in the Metropolitan Street Railway Company:

They are willing to organize a new corporation, hereinafter called the Tunnel Company, which shall agree with satisfactory guarantees of performance to build with private capital and maintain and operate the underground rapid transit road on the route and plans of the commission, with some possible modifications in detail, as to space for stations, places of access, width of tunnel, etc., which may be suggested by engineers and approved by your board, and upon the following terms:

1. The road to be constructed in two sections.

(*a*) The first section, from the southern terminus to a point between Fort George and the ship canal, to be constructed immediately, the work to be commenced within three months and to be completed within thirty-six months after the right is acquired.

(*b*) The second section to comprise the remainder of the entire route on both branches, to be commenced as soon as the net earnings from the operation of the railroad upon the first section shall be sufficient to pay 5 per cent upon the actual cost of construction and equipment, and to be completed within twenty-four months thereafter.

Reasonable provision to be included in the contract for extensions of time in case of litigation or other delay for which the Tunnel Company is not responsible.

2. The railroad to be operated in connection with the Metropolitan Street Railway and to be leased to the Metropolitan Street Railway Company in perpetuity, or for a term practically equivalent thereto, for a rental to the Tunnel Company of 5 per cent upon the actual cost of construction and equipment.

3. The fare on all cars or trains, except those hereinafter described as express, to be five cents. This to include all cars or trains run on the outside tracks. All passengers carried for five cents to be entitled to be carried over the surface lines of the Metropolitan Street Railway Company for an additional three cents. Conversely, all passengers over the surface lines of the Metropolitan Street Railway to be entitled to be carried over the tunnel road on cars and trains, other than express, for a fare of three cents in addition to the present surface railway fare.

Such carriage of passengers over the joint lines of the Metropolitan Street Railway Company and the new road to be by continuous car passage as well as by transfers, unless it shall be determined that the running of the same cars on both roads would unduly interfere with the capacity or speed of the tunnel road.

Track connections with the surface lines for the continuous passage of cars to be made (or special transfer stations to be established):

(*a*) At or near Thirty-second Street for the Lexington Avenue, Second Avenue and Thirty-fourth Street and Long Island Ferry lines by bringing in tracks from those lines through private property to be purchased by the Tunnel Company between Thirty-second and Thirty-third Streets and Fourth and Lexington Avenues.

(*b*) At or near Forty-second Street for the Madison Avenue line.

(*c*) At or near Fifty-ninth Street for the Eighth Avenue line and the Fifty-ninth Street crosstown line.

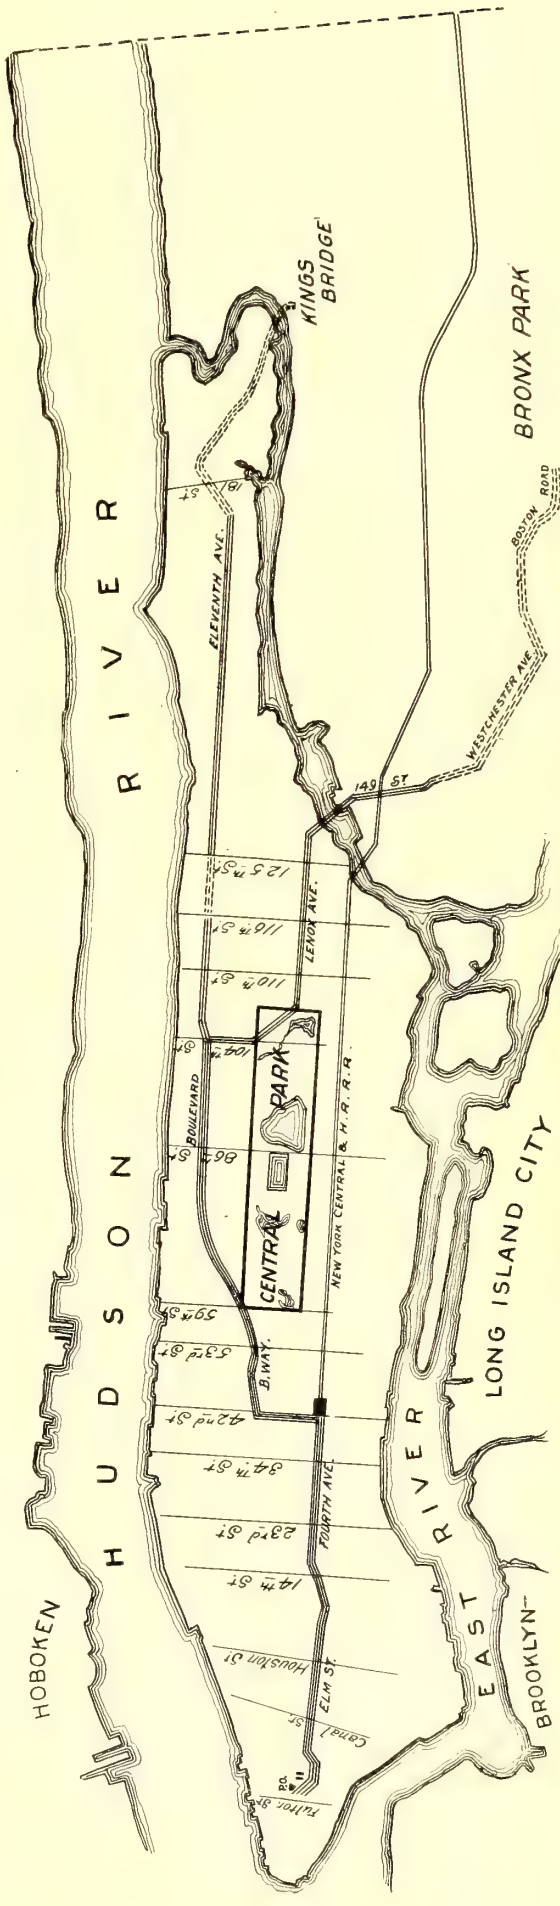
(*d*) At or near Fifty-fifth Street for the Columbus Avenue line and the Boulevard and Amsterdam Avenue line.

Special provision is to be made for delivery of passengers to and taking passengers from the lines of the steam railroads using the Grand Central railroad station at Forty-second Street, and joint traffic arrangements to be made with the New York & Harlem, New York & New Haven and New York Central (provided those companies consent) for carriage of passengers between all points on their lines within the city limits and the southern terminus of the new road.

4. Express trains to be run on the tracks marked as express tracks on your plans, and upon them the fare to be ten cents, provided that the passengers upon all such trains shall be entitled to be transferred to and carried on all other cars or trains on the new road without payment of any additional fare; and to be transferred to and carried upon all connecting lines of the Metropolitan Street Surface Railway without the payment of any additional fare; and that passengers on all other cars and trains on the tunnel road shall be entitled to be transferred to such express trains on the payment of five cents additional fare; and that passengers on all connecting surface lines of the Metropolitan Street Railway shall be entitled to be transferred to and carried on said express trains on the payment of five cents in addition to the present street surface railway fare.

No train to be deemed an express train except one which is scheduled to run and, barring accidents, does customarily run, over its entire route below Ninety-sixth Street at the rate of 20 miles an hour, and for at least two miles below Forty-second Street at the rate of 30 miles an hour.

5. Provision to be made for a third track on both the eastern and western branches above Ninety-sixth Street, so that express trains may be run down in the morning and up in the evening over the entire road.



6. The new company to be entitled to use the side galleries and other spaces in the tunnel not necessary for railroad purposes for any wires, tubes or conductors authorized by law, belonging either to itself or others, and to receive to its own use any rentals which may be derived therefrom.

7. The city to receive as compensation, in addition to the services rendered and in lieu of all other charges upon the franchise granted hereunder, an annual rental equal to 5 per cent on the gross receipts from the operation of the new road; provided that whenever any such payment shall leave the receipts insufficient to pay the rental of 5 per cent on cost of construction and the operating expenses, including taxes, the percentage to be paid shall be abated accordingly.

8. The real and personal property forming part of said railway to be exempt from taxes until it pays 5 per cent, as provided in section 15 of the rapid transit act, with the amendments proposed by the commission in the bill now pending before the Legislature.

9. Adequate station room to be given under City Hall Park, without interfering with the surface, except for access from the street and park, which is to be given by sufficient stairways. Similar provision to be made for underground stations, and sufficient access from the open spaces at the junctions of Broadway with Seventh and Eighth and Columbus and Amsterdam Avenues.

In all matters not covered by the present construction plans, such as crossings and connections with surface lines, not heretofore contemplated by these plans, the construction to conform to the requirements of the commission's engineers in all matters relating to the public safety or to the use of any portion of the streets, avenues or public

Underground sections are shown by solid lines, viaduct sections by dotted lines.

PROPOSED ROUTE OF RAPID TRANSIT RAILWAY, NEW YORK

places of the city. All sewers, pipes or other sub-surface structures now in the streets, and which may be interfered with by the construction of the tunnel, to be relocated and provided for at the expense of the Tunnel Company, in accordance with your plans and to your satisfaction.

10. The cost of construction to be deemed to include the cost of all private property purchased for connections, stations, etc., and a fair proportion of the costs of any power houses, machinery, or other plant constructed or acquired for the joint operation of the new road and the surface roads of the Metropolitan Street Railway Company, the expenses of organizations, plans and contracts and interest during construction. The accounts, vouchers, and payrolls showing the cost of construction and the earnings of the new road to be at all times open to your inspection.

11. The earnings of the new road to be ascertained by taking all the fares received for the separate business of that road and by an equal division between the new road and the Metropolitan surface road upon all joint business. In case any difference should arise between the Tunnel Company or the Metropolitan Street Railway Company and your board, or the city of New York, under the contract, the question to be submitted to the determination of three arbitrators, one to be selected by yourselves, one by the Metropolitan Street Railway Company, and the third chosen by the two so selected.

This proposal is subject to the approval of the stockholders of the Metropolitan Street Railway Company in the manner provided by law. Very respectfully,

Root, Howard, Winthrop & Stimson.
Jay & Chandler.

New York, March 27.

Accompanying this memorandum was the following letter of explanation giving the company's reasons for making the offer:

POSITION OF THE METROPOLITAN EXPLAINED

Alexander E. Orr, Esq., President Board of Rapid Transit Railroad Commissioners:

Dear Sir—We inclose a memorandum of the terms upon which gentlemen interested in the Metropolitan Street Railway Company will undertake to form a corporation to construct the underground rapid transit railroad, on the route and plans proposed by you, and to provide for its maintenance and operation in connection with the Metropolitan Street Railway system. The memorandum has been submitted to the Metropolitan Street Railway directors and has their approval.

You will perceive that the plan contemplates the construction of the road by private capital, and giving transportation on it without any additional charge beyond the cost of transportation, to all passengers on the Metropolitan system of roads, which now extends through about 250 miles of streets, and carries about 900,000 passengers daily. The only exception to this practically free use of the tunnel road would be in the case of express trains, running for long distances without stops, and therefore without the short-haul business, from which alone the profits of street railroads are now made, and running at a high rate of speed, which necessitates greater headway and fewer trains, and therefore smaller returns. As to this class of business a fare is stipulated, which would be practically a fare of five cents for the use of the tunnel road, added to the fare of five cents upon which the same passengers would be entitled to travel over the surface lines.

The regular fare provided for passengers not desiring to use the surface roads is five cents.

This plan results from the following considerations, suggested to our clients by their experience in street railroad transportation in New York:

1. That the reason why capital has not responded to the long-continued invitation of the city to take the risk of constructing an underground road is that there is not sufficient probability that such a road, in view of its great cost, could be operated profitably on an independent basis as a trunk line without branches or feeders.

2. That such a road, without any means of collecting and distributing passengers over surface lines, would afford only very partial and unsatisfactory facilities to the people of the city, most of whom would either be obliged to walk long distances to reach the stations, or pay double fares on independent surface lines.

3. That since the introduction of the underground system of electric traction, the real obstacle to rapid transit is to be found in the congested condition of the streets in the lower part of the city, and that if the same electric cars now used, or similar cars connecting with them, could be propelled swiftly through a tunnel from Harlem to the City Hall, the tunnel road being used as a trunk line, while the surface roads are used for local traffic and the collection and distribution of passengers for the trunk line, real rapid transit would be attained.

4. That while the tunnel road itself would afford to the most northerly districts of the city the convenience they have so long sought, its combination with the surface roads would give much needed relief to the great population extending from Forty-second Street to Harlem, and especially to the residents between the line of the Central Park and East River, who would otherwise receive little benefit from the new road.

5. That the close connection of the underground road from the City Hall to Forty-second Street with the New York Central, New York & Harlem and New York & New Haven Road at that point would, in effect, make a rapid transit route from the City Hall to every point within the city limits on the four lines of the railroad companies mentioned.

6. That the increase of business which would result from the increase of facilities thus afforded would probably justify the assumption of a burden by the Metropolitan Company for the construction of the new road, which would be altogether beyond the possibility of profitable investment if the road were to be built and operated independently; and that the Metropolitan Company could probably operate the new road more economically and effectively than any independent company, and might thus make a profit where such another company would fail.

7. That the special facilities which the Metropolitan Company now has as lessee of the New York & Harlem's right to the Fourth Avenue tunnel between Thirty-fourth and Forty-second Streets, and through owning or controlling large tracts of land immediately available for use, and especially in the possession of plant for the production of power, containing provisions for large increase of future requirements, and which it has been engaged for years in construction, put that company in such a position that it can have a rapid transit road in actual operation long before that would be possible for any one else, even if any one else were now willing to undertake it.

It is now several years since the people of this State adopted a new policy regarding city railroads by repealing the statutes which prohibited, and passing laws which favored, the consolidation of street railways on condition that greater facilities should be afforded to the public in the way of transportation over the combined lines without additional fares. The result of the new policy in this city as compared with the former system of numerous inde-

pendent lines presents a most remarkable exhibit of public benefit. The Metropolitan Company is now carrying upon transfers for which no payment is made, over lines which would, under the old system, have been entitled to two separate fares, about 400,000 passengers daily. The money which would be paid by the people of the city for this service, which they now get for nothing, would, if the old system still continued and the people received the same service, amount to over $7,000,000 annually. The average fare paid to the Metropolitan Company for each single ride, such as would have been given for five cents under the old system, is now but three and one-half cents per passenger. What this means to the business of the city, in the convenience of access to its stores for the purposes of trade, in the freedom of its working people as to the selection of their homes without being tied down to the immediate locality where their work is to be done, in the equalization of rents and in the convenience to the public generally, it is impossible to estimate. The plan which we propose is but a continuance of the same wise policy.

We are satisfied that this offer presents to the people of the city advantages superior to any plan hitherto suggested and fully commensurate with any benefits to be derived by the new company or by the Metropolitan Street Railway Company, and that it will produce for New York a system of urban transportation far better than that now existing in any great city of the world. The difficulties and risks involved are such that no one can safely assume them without popular support, and we make the offer in the belief that the people of the city of New York will regard the arrangement proposed as fair and advantageous to them, and will be ready to give it their genuine approval and support. Very respectfully,

Root, Howard, Winthrop & Stimson.
Jay & Chandler.

H. H. Vreeland, the president of the Metropolitan Street Railway Company, said the proposition is the final word of the company on the subject.

"This is the second proposition we have made to the Rapid Transit Commission," he said, "and our letter to them contains our final decision in regard to the plan of an underground rapid transit tunnel. On our part the case is closed, and we are waiting for the verdict. There cannot be any haggling over the proposition, so far as we are concerned, for we have examined the whole project in all its details, and have decided exactly what we are able to do. This has been embodied in the communications to the Rapid Transit Commission, and our conclusions and offer are before them to accept or reject. The proposition before them is final.

"The details of our plan are fully explained in the letters to the board. If our offer is accepted, we shall endeavor to use the tunnel for the through traffic first, and for as much local traffic as can be accommodated in it without interrupting or delaying the express traffic. Whether there will be any objection to the grant of the franchise in perpetuity I cannot predict, but if the matter is considered practically a person must see that it would be ridiculous to ask us to risk so great an amount of money on a short leasehold."

Asked if the control of the rapid transit tunnel by the Metropolitan Company would not lead to the absorption by that company of all lines of other companies in the boroughs of Manhattan and the Bronx (including the elevated system), Mr. Vreeland said: "I believe that eventually all of the railway transportation lines on Manhattan Island will be under the control of one company. It may be the Metropolitan Street Railway Company, or it may be some other company. It seems to me that conditions and circumstances are tending in the direction of concentration of control. If there is to be a perfect system of passenger transportation on this island such as the people want, it naturally must be under one management. Of course, I cannot foretell what is going to happen years hence, and know of no definite plans beyond the fact that the Metropolitan Company stands ready to carry out its proposition to construct and operate the tunnel.

"Is it not significant that in all the years that underground rapid transit has been discussed here in New York no combination of capitalists has been able to figure out financial success in the project? It is the Metropolitan Company's peculiar position that enables it to undertake this great work with hope of financial success. We already have 228 miles of surface lines in operation, and each succeeding year the pressure of traffic is increasing. At certain hours of the day we are unable to carry all of the people who want to ride. It is by making the proposed rapid transit tunnel a part of our system—the trunk line, if you please—that we are able to see a profit in its construction and operation.

"The tunnel road will undoubtedly relieve the surface lines of practically all the long-haul traffic, thereby enabling us to carry all of the short-trip passengers on our surface lines at all hours of the day. At the present rate of increase in traffic, the relief thus afforded by the tunnel will, two or three years hence, be an actual necessity. You can readily see, therefore, that the operation of a great trunk line tunnel, with express and local trains, in connection with our otherwise far-reaching system, would naturally lead to the control of the passenger transportation facilities of this island by one concern."

President Vreeland said that if the franchise for constructing the tunnel was given to the Metropolitan Company, he thought that cars could be run through at least one section of the tunnel within two years from the time of beginning work. "I do not mean," he said, "that we would build the tunnel a section at a time, for we should begin the work at several different points and push it as expeditiously as possible all along the line. But in case one section should be completed before the others, it would not be necessary for the completion of the whole tunnel to begin the running of cars. There is where one great advantage of the Metropolitan Company as the constructor of this tunnel is manifested. We have sufficient electrical power to enable us to operate cars in any part of the tunnel just as soon as a section can be opened. For instance, should the sections between the City Hall and Thirty-second Street be completed before the sections further up town, we could make a physical connection between the tunnel and our Lexington Avenue line and run cars through the tunnel and over the surface lines from City Hall to Harlem.

"The Metropolitan Street Railway Company owns the block bounded by Fourth and Lexington Avenues and Thirty-second and Thirty-third Streets. The grade of Lexington Avenue is so far below that of Fourth Avenue that, by an easy incline, connection between the surface line and the tunnel could be made at this point. So you see that the people of New York would be able to enjoy the advantages of partial underground rapid transit without waiting until the entire tunnel is finished. In most cases, as different sections of the tunnel were completed, they could be operated in a similar manner.

"As has already been stated, the transfer system as it now prevails on the Metropolitan lines would be applied to the tunnel, with the exception that three cents additional fare would be charged for each transfer to and from the tunnel. This extra charge we feel bound to make in order

to get a profit out of the operation of the tunnel. On all local trains in the tunnel, however, the fare will be five cents. I do not believe that any reasonable objection can be urged against our charging extra for the fast express train service in the tunnel."

Mr. Vreeland reiterated that work would probably be begun in the construction of the tunnel within three months after the details of the franchise have been closed up by the contracting parties. He said: "We know just what kind of ground we have got to cut through, and just how many feet of rock must be blasted. All of this information has been ascertained by competent engineers, and the data and specifications on which to proceed with the work are at hand."

RAPID TRANSIT BOARD MEETS

The Board of Rapid Transit Commissioners held a special meeting March 29, at noon, in the rooms of the Chamber of Commerce, for the purpose of considering the proposed memorial to the Legislature and the amendments to the rapid transit bill, which the proposition to build the underground road by means of private capital has made necessary.

The commission considered very fully the proposed memorial and amendments, and took such action as will result in the placing of both before the Legislature by the evening of March 30. After the discussion of the memorial, the following resolution was offered by Mayor Van Wyck:

Resolved, That it is the sense of this board that it is in the public interest that, in addition to the powers already possessed by the board, the Legislature should grant to the board the power to contract for the construction and operation of the Rapid Transit Railroad by private capital.

This resolution was unanimously adopted.

Mr.Starin then offered a resolution that the president and secretary be authorized to execute the proposed memorial as drafted in behalf of, and under the seal of, the board, and to forward the same to both houses of the Legislature. This motion was also carried.

Proposed New Subway in Boston

A new subway, beginning approximately at the Boston end of the Harvard Bridge and extending along the water front back of the Beacon Street houses, up under Beacon Hill to Scollay Square, with convenient entrances and exits, has been proposed by Mayor Quincy of that city in a hearing before the State legislative committee on metropolitan affairs.

Such a subway would cost about $2,500,000, and would do away with the necessity of running surface cars on Marlboro Street to accommodate the people of the Back Bay. With a surface line on Boylston Street and a subway along the southerly shore of the Charles River, the residents of that section bounded by Arlington Street, Boylston Street, Massachusetts Avenue and the Charles would have ample facilities for reaching the business portion of the city. More than that, the proposed subway would entirely relieve the congestion which now exists in and about the present subway.

Into the new tunnel would be sent the electric cars which come across the Harvard Bridge from Cambridge, and also those from Newton, Brighton and Allston, which now run down Beacon Street to Massachusetts Avenue, where they go on the same track used by the Cambridge cars. Every one of these cars, under the conditions which now exist, continues its course down Boylston Street and into the subway at the Public Garden. All these cars could be run in the new subway. Thus the old one would be relieved of more than half of its burden.

There would be no longer any agitation for the replacing of car tracks on Tremont Street. Such a step would not be necessary.

The construction of this subway is but one, although it may be in some ways the most important, feature of a plan for the improvement of the south bank of the Charles River. The subway would not have been suggested if it had not been for the esplanade which is to be built back of the houses which face on Beacon Street. Under that esplanade the subway will be.

This esplanade has been for a long time contemplated. Last year a bill providing for the construction of such a plat was presented to the Legislature. This measure, which provided for the erection of a new river wall 40 ft. north of the present wall, and for the filling in of the space between the two walls, was advocated by Mayor Quincy, assented to by the adjacent landowners, who were to pay about one-half the cost, and approved by the harbor and land commissioners. But the Legislature of 1898 referred the bill to the next General Court, the Legislature of this year. Mayor Quincy now proposes to build the esplanade 75 ft. wide, and under it to construct the subway.

Blood's Formula for Train Resistance

Owing to a typographical error which occurred in the article by Mr. Blood, on train resistance, in the last issue of the Journal, after the page was read by the editors, the exponent n of the speed M in the third term of Mr. Blood's general formula, was omitted, although the formula is correctly given later on, when a value is selected for n. The correct reading for Mr. Blood's general formula is, therefore, as follows:

$$R = B + W M + A\frac{M^n}{T}$$

Where

R = resistance.
M = speed.
T = weight of train.
B = journal coefficient.
W = wheel and rail coefficient.
A = air resistance coefficient.
n = exponent of air factor, which should be determined by experiment.

So the smaller companies, while they may not be quite as extensive as some of the more prominent ones of this association, certainly are just as wide and broad in their possibilities of growth and development as any that are now recorded upon our roster.—From address at the Atlanta, Ga., Convention, 1894.

From these comparisons, we see that with the lives assumed, cypress will cost 48 per cent more than creosoted timber. Oak will cost 92 per cent more than creosoted timber. Pine will cost 111 per cent more than creosoted timber.—From paper read at the Montreal Convention, 1895.

Sans Souci Park, Chicago

Chicago has a grand system of public parks, large and small, located in all parts of the city, and with a connecting system of boulevards which is the pride of every resident. The large parks are all situated advantageously to the street railway companies, and it is doubtless that this fact has heretofore deterred the street railway companies from creating amusement resorts such as have been established in other cities.

Sans Souci Park, which is now in preparation, is the first amusement resort of any magnitude in Chicago which has for its object the stimulation of street railway traffic. It is located on the Wabash Avenue line of the Chicago City Railway and well out toward its terminus. The Sixty-first Street electric line of the Chicago City passes along one side of the park, and the Alley L and Illinois Central are within a block. The park and buildings will cover the entire block, extending east from Cottage Grove to Langley Avenue between Sixtieth and Sixty-first Streets. This location will be remembered as being at the southeast corner of Washington Park, and at the entrance of the Midway, which is now one of the most popular boulevards of the city. In summer the surrounding drives are filled with bicycles and carriages. It is doubtful if there exists within the city limits a better available location for a street railway park.

FIG. 1.—FLOWER VASE PARTLY COMPLETED

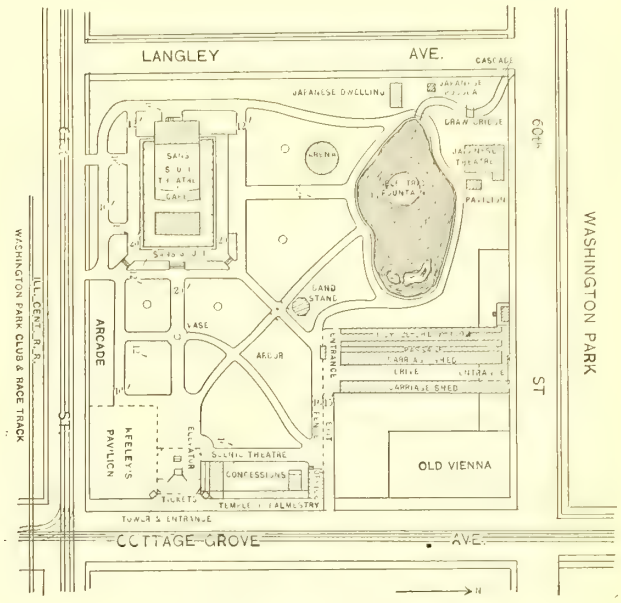


FIG. 2.—PLAN OF PARK

The park is square, with an inclosed area of nearly ten acres. The buildings and rubbish which occupied the ground were all removed, except "Old Vienna," itself a summer resort, which stands on one corner; the lease to the present occupants of "Old Vienna" has yet two years to run, after which the building will be removed and the park extended over the space occupied.

The park has been laid out with fine walks, the general arrangement of which, with entrances, buildings, etc., is shown on the diagram Fig. 2. The lawns, which are now covered with a heavy coating of manure, will soon be sodded. There were originally no trees on the ground, but a goodly number have already been transplanted. A strong high fence will surround the park, and a small admission fee is to be charged.

The principal attractions will be the Sans Souci open-air theater and café and the electric fountain. The pavil-

FIG. 3.—THEATER BUILDING AND BAND STAND

ion, or theater building (Fig. 3), is an attractive two-story frame structure, painted white, except the roof, which is of red tile. The extreme dimensions of the building are 145 ft. x 180 ft. In the eastern end the lower floor will be occupied by a buffet, 50 ft. x 70 ft., and directly over

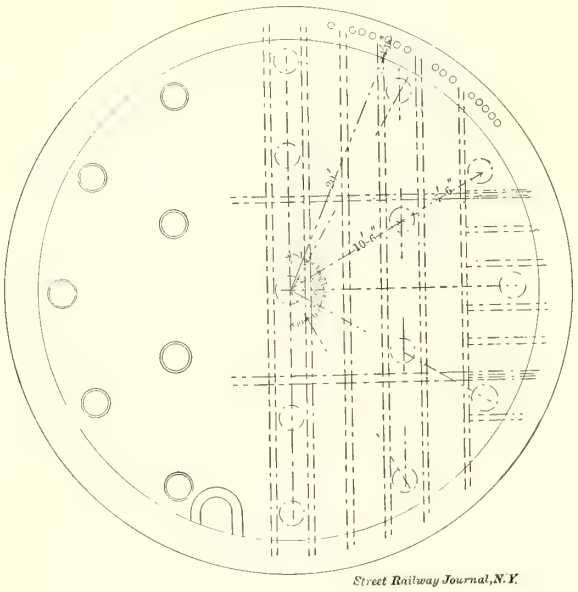

FIG. 4.—PLAN OF ELECTRIC FOUNTAIN

this, in a room of the same size, will be the kitchen. At the other end of the building is a stage 30 ft. x 42 ft., dressing rooms and large, well-furnished public lavatories. In the center of the building is the auditorium of the theater. It connects with the broad porticos on either side, which are continuous on three sides of the building. The stage is in full view of the verandas and the promenades connecting them; visitors will be free to view the performances from the verandas, but a charge will be made for the reserved chairs in the parquet and balcony, which are inclosed by a light railing. The seating capacity of the pavilion, exclusive of the theater auditorium, is 2500; the latter will be furnished with 850 chairs. Accommodations for seating nearly as many more people will be made in the park surrounding the band stand and fountain.

Judging from the popularity of the small fountain in Lincoln Park, it is expected that the electric fountain at Sans Souci will prove a great attraction. This fountain, a plan of which is shown in Fig. 4, is circular in shape, with a diameter of 48 ft. The outer wall is laid with blocks of steel slag, and this is surrounded by a small lake, as shown in the plan (Fig. 2). The fountain is one of the largest ever constructed, and will have eighteen wells.

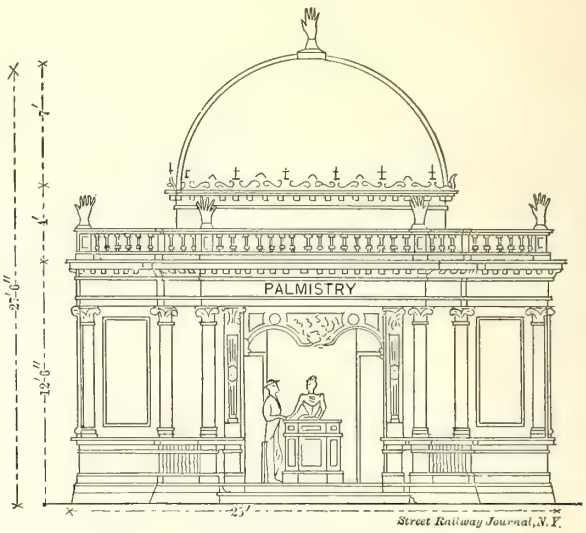

FIG. 5.—THE TEMPLE OF PALMISTRY

The operating machinery will not be controlled, as is usual, by attendants in the base of the fountain, but from the power house. This is a small building, 16 ft. x 20 ft., three stories high, built at the edge of the surrounding lake. In the basement will be installed two Quinby screw pumps, with a capacity of 1000 gals. per minute. Each pump will be direct connected to a 75-h.p. Westinghouse motor. Current for operating the motors will be taken from the trolley circuit.

On the second floor of the power house will be a switch board with some 380 push buttons, the manipulation of which will vary the colors of the fountain, and small controlling valves for governing the Crane hydraulic lift valves, which in turn govern the water display. The manipulation of the fountain will require the attention of but one attendant. The third floor of the power house, with stairways leading up to it, will be an open pavilion. It is the intention to operate the fountain each evening during the summer months.

The fountain was designed by Messrs. Moore and Riley,

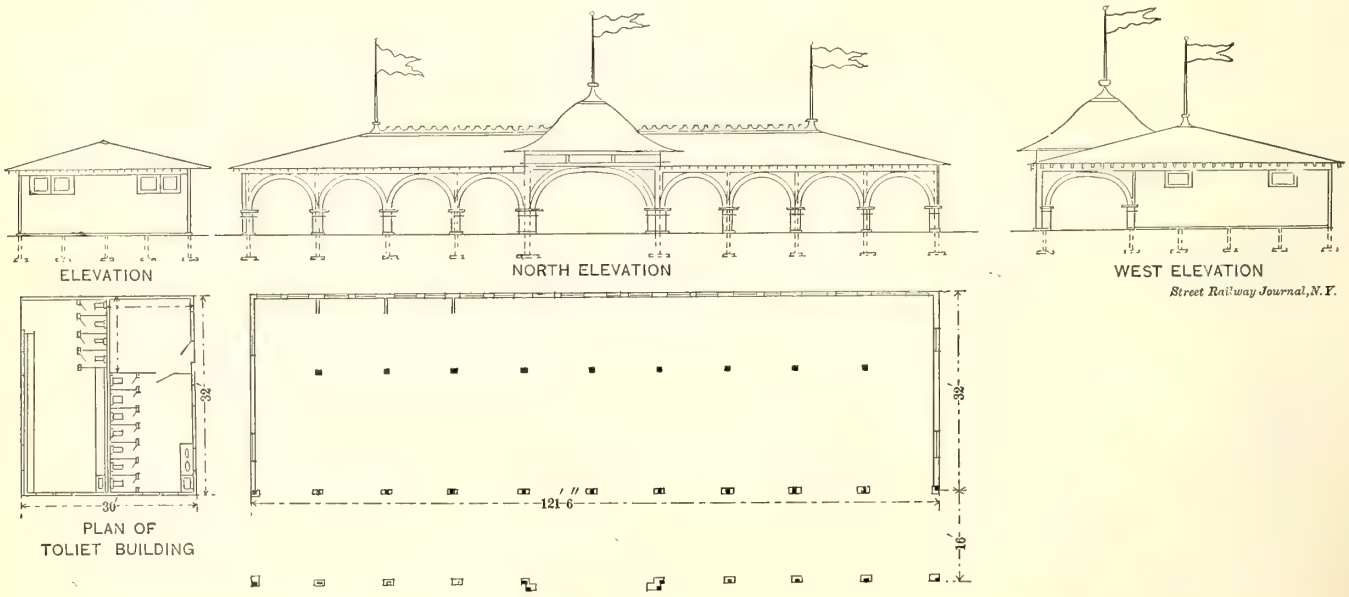

FIG. 6.—PLAN AND ELEVATIONS OF ARCADE

of the Chicago City Railway, and the machinery and parts have nearly all been made in the company's shops. Its cost in round figures is $25,000.

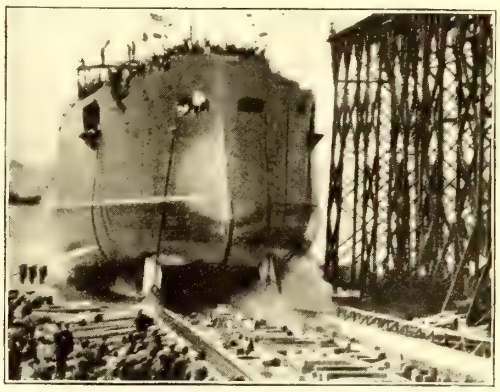
The band stand, which is shown in Fig. 3, is octagonal, 24 ft. in diameter. Band music will be a practically continuous feature of the park's attractions. Fig. 1 shows a large flower vase that is being erected. In one corner of the grounds will be located a Japanese theater and tea garden. Two of the principal buildings at the park will be the "Arcade" and the Temple of Palmistry, plans of which are shown in Figs. 5 and 6. The Arcade will be a well-constructed building, 121 ft. 6 ins. long x 48 ft. wide. It is proposed to sublet floor space in this building for various booths and attractions, as photograph galleries, candy stands, cane, knife and shooting galleries, etc. No partitions will be built in the building at first, but these will be added to suit the different tenants. The Temple of Palmistry is a neatly-designed pavilion, and will be used for telling fortunes and reading characters.

The park has been promoted by the Chicago City Railway Company, but W. H. Carter is the proprietor and manager.

Attractions for Parks

The Biograph

The increasing number of street railway parks makes the subject of park amusements particularly interesting to street railway companies, and for this reason a number of those attractions, which have proved most popular, have been described in these columns. In this series some particulars of the biograph will undoubtedly be of interest, as this machine, which has been so successful as a theatrical attraction for the past four years, last summer entered the field of summer parks and demonstrated its crowd-drawing qualities in a notable way.



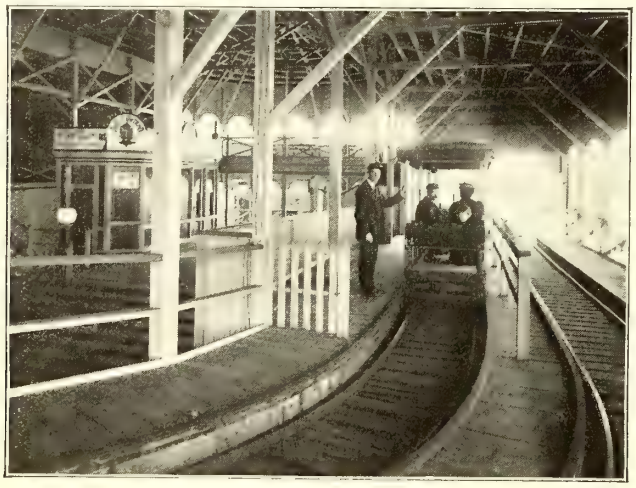
PRESIDENT MCKINLEY AT CAMP WYCKOFF

At the Denver City Park the American biograph was shown, last summer, as a free attraction by the Denver Consolidated Tramway Company. Park Commissioner Gallup is quoted as saying that the biograph attracted to the park between 300,000 and 500,000 people. In the Denver City Park the screen was placed upon a barge moored out in a lake, the projecting apparatus being placed upon the shore. In this way the pictures were viewed by an immense crowd, and during the intermissions between the biograph shows the screen was rolled up out of the way and the barge utilized as a band stand. It is not necessary to darken the park or to do away with any of the illuminations, as the biograph requires only a darkened screen.

There are many strong arguments in favor of the biograph as an attraction for summer parks. It draws a large number of people who, for various reasons, are not interested in ordinary vaudeville entertainment, and, at the same time, its pictures are so varied that it appeals forcibly to the regular summer park patrons. It is claimed for the biograph that on consecutive evenings it gave the same programme on the Bowery and at the Waldorf-Astoria in New York city; in each case the audiences showed the same enthusiastic approval. In parks where refreshments are sold, the biograph commends itself particularly as an attraction which augments the ordinary café trade. A crowd seated about tables or promenading can enjoy the pictures as well as one seated in a hall, and no amount of conversation or laughter can interfere with the success of the programme. Of course, the biograph is equally adapted to indoor work. It is to be recommended particularly, however, as a free outdoor attraction for the purposes of drawing crowds and holding them. In order to do this two shows are given, one at 8 o'clock, at the conclusion of which it is announced upon the screen that another and entirely new set of pictures will be shown at 10 o'clock. This method has always proved very successful. The biograph should not be confused with other moving picture projecting machines. It operates on a much larger scale, throwing a clear, steady picture 30 ft. sq. and uses a film 2¼ ins. wide, which is said to be seven times greater than that used in other apparatus. The American Mutoscope Company, of New York, which owns and operates the biograph exclusively, is affiliated with similar companies in London, Paris, Berlin and other foreign capitals, and the films obtained by any one of these companies is at the disposal of the others; thus the American Mutoscope Company has been enabled to show in America such scenes as the Victorian Jubilee Parade, the Coronation of Queen Wilhelmina, of Holland, the Inauguration of President Loubet, of France, etc., even before the illustrated papers have had their illustrations. The engravings which are shown herewith give an idea of the variety of subjects and of the general character of the pictures shown by the biograph.

A ROTARY SNOW PLOW IN ACTION

LAUNCHING THE U. S. BATTLESHIP ILLINOIS



Scenic Railway at Coney Island

One of the most popular attractions at Coney Island, itself one of the most popular pleasure resorts in the world, is the scenic gravity railway. This is situated near the west iron pier, and although somewhat out of the way in its location, it has nevertheless been discovered and patronized by over a million people during the past three seasons, and it is a noteworthy fact that those who take this ride never fail to express their appreciation of this amusement.

The structure consists of four parallel tracks, each one about 800 ft. long, making a total ride of about 3200 ft. The tracks are built with alternate elevations and depressions, giving the cars a wavy motion which is novel and agreeable. At the outer end of the railway is a large auditorium through which the four tracks pass, and it is here that the scenic effects are produced. The railway depends for its popularity on the surprise and wonderment occasioned by the suddenness with which the scenic effects are

brought into operation. This is accomplished by making the approaches and exits to the rooms in which the scenic features are located, long dark tunnels. The tracks for several feet before reaching these rooms are carefully bonded and are at all times connected with a source of electricity, but the circuit is not closed, and there is, of course, no current in the rails. As soon as the car approaches these points, however, the wheels and axles complete the circuit from one rail to the other and immediately the car is surrounded by a brilliant illumination disclosing on all sides the most weird and surprising scenery. The car dashes through this illumination and suddenly all is darkness again. The scenic effects on the four tracks are different, so that the excitement is kept up during the whole trip. Some of the scenes installed are shown herewith.

Every precaution is taken to make the operation of the cars absolutely safe, powerful track brakes being placed upon each car. In addition to this, an automatic safety signal block system is in use, making rear end collisions impossible. Each car is in charge of a competent attendant.

STARTING ON THE RIDE

WINTER SCENE

VIEWS IN ONE OF THE CAVERNS

This scenic railway was installed and is owned by the L. A. Thompson Company, of New York, it being one of a number of these attractions which this company has installed throughout the country. In addition, this company has built scenic railways at Bergen Beach, Woodside Park, Philadelphia; Toledo, Ohio; Riverside Park, Baltimore; Midland Beach, Staten Island, and Chester Park, Cincinnati. Orders are also being received from foreign countries, a complete railway with all the necessary materials, accessories, etc., having just been shipped to Para, Brazil.

Dramatic and Vaudeville Attractions

The difficulty of obtaining good vaudeville and dramatic attractions at short notice for parks, summer gardens, etc., has led Daniel Packard, of New York city, to open a general headquarters for this class of artists.

Mr. Packard has the addresses of and is in business relation with a very large number of the leading musicians, singers, lecturers, pianists, magicians and vaudeville artists in the country, and is prepared to furnish entertainments for one evening, or for any length of time, of any class desired. He will furnish a quartette, a singer, a magician, a minstrel first part, a singing soubrette, or an entire vaudeville or opera company. He has had twenty years' experience in organizing summer attractions, and has given special attention to the requirements of open-air theaters. He supplies all the necessary costumes and music, and attends to all the rehearsing and preliminary arrangements.

Large Contracts in New York

The Third Avenue Railroad Company, of New York city, in addition to the contracts mentioned in the Street Railway Journal for January, 1899, has recently awarded the following: St. Louis Car Company, of St. Louis, 100 cars; Peckham Truck Company, of New York, 100 pairs 14-B short wheel-base trucks and 60 pairs Peckham maximum traction trucks; Standard Air Brake Company, 160 Standard air-brake equipments; E. F. DeWitt & Co., Lansingburg, N. Y., sand boxes for 160 cars; Hale & Kilburn Manufacturing Company, Philadelphia, car seats.

Municipal Ownership in Detroit

The Michigan Legislature on March 23 passed a bill providing for the municipal ownership of street railways in the city of Detroit. The bill states that three commissioners shall be appointed by the Detroit Common Council to arrange the terms of purchase, which are to be ratified by the Common Council before the agreement is closed.

It is understood, however, that the Detroit companies' franchises are so worded as to prevent the carrying out of the provisions of the new bill.

LEGAL NOTES AND COMMENTS*

Edited by J. Aspinwall Hodge Jr., and Robert Ernest, of the New York Bar

Bribery and Perjury in Accident Cases

The role of Cassandra is neither grateful nor popular. Even the pessimist, who confines himself to a doleful view of existing conditions and does not attempt to prophesy or to point out the probable result of growing tendencies, is not generally listened to with favor, and often is not credited.

But both the existing conditions and the tendency to corrupt practices in the trial of negligence cases, especially in the courts which are crowded with them in the large cities, is becoming so apparent and notorious that it is felt that a note of warning will not be out of tune with the general knowledge and thought of our readers.

A somewhat extensive inquiry addressed to a number of lawyers who, in our large cities, devote their time, some of them to the defense and some of them to the prosecution of negligence cases, especially against street railways, has resulted in a practically unanimous verdict that corrupt practices are increasing. A difference of opinion emerges only when the inquirer seeks to obtain an opinion from men, who look at the matter from different standpoints, as to whether the plaintiffs or the defendants are the greater sinners.

Our own view of the matter is, that, where a great volume of business is transacted of any sort, and one side or class of men seek to attain their ends by trickery or fraud, that the other side will, in a very great number of cases, seek to justify themselves in stooping to similar means on the ground of self-defense and self-preservation. It has been the experience of most men in the profession that the plaintiffs' attorneys are generally the first to sin, and have the least excuse. They deal oftentimes with ignorant people; they have but few cases as compared with the attorneys for the railways; they come into personal contact with both client and witnesses, and they can give personal attention to details and, presumably, can secure, at first hand, reliable information as to the honesty and justice of their cases. It takes a very stupid lawyer, who can give his attention, personally to the investigation of an accident case, to be deceived by witnesses who propose to perjure themselves for the benefit of the plaintiff.

On the other hand, the temptation offered to an attorney, especially if he be poor, to make sure of a large verdict, in a flimsy case, is great, for the stake is large, and the whole matter is of so speculative a nature as to present the attractions and temptations of a gambling transaction, with what seems to be a small fortune in view in case of success, and actual loss in case of failure.

Now and then the public is apprised of the facts, which are more surprising and startling to them than to the lawyer, who often suspects, from what he sees in the courts, trickery and dishonesty he cannot prove.

Recently in New York a case came before one of the trial courts where the plaintiff's attorney placed witnesses on the stand who testified; that an employee of the defendant was driving a large truck, heavily laden, through a crowded thoroughfare, and by his side sat a boy some seventeen years old; that the plaintiff, an infant, was standing in the middle of the street, watched by his mother on the sidewalk; that the wagon ran over the child, and that at the time the driver was reading a book, while the boy at his side was holding the reins and driving.

The defendant's testimony was to the effect, that the driver had the reins and had no book, and that he called to the child, and that thereupon the mother rushed into the street and the accident happened. The jury brought in a verdict for ten thousand dollars in favor of the plaintiff, who had been severely injured. After entry of judgment the attorney for the defendant learned that one of the witnesses for the plaintiff had stated in conversation that he had sworn falsely at the trial. Investigation followed, which resulted in the indictment and arrest of this witness, and of several others, who confessed, some to the district attorney and some to the attorney for the defendant, that they had been guilty of perjury at the trial; that some of them had not been near the scene of the accident at the time it happened, and that the others gave a perverted account of what they saw. They stated in their confessions that the plaintiff's attorney read to them a carefully prepared version of the accident, including an account of the book and of the boy having the reins in his hand, and they testified to what had been read to them, and not to what they had seen.

Meanwhile an appeal from the judgment had been taken to the appellate court, and the verdict had been sustained; but the judgment of affirmance was not entered promptly by the plaintiff, and a rather interesting state of facts must be recited as the cause of the delay.

It appeared that the attorney for the plaintiff had a large financial interest in the case, and in several other actions (for loss of service, etc.) arising out of the same accident. To save expense, the plaintiff had brought his action as a poor person, and the plaintiff's attorney had made the necessary agreement to prosecute without compensation, but after the decision of the appellate court he refused to enter up the judgment of affirmance until the guardian of the infant plaintiff would agree that he should receive full costs, allowances, expenses, and several thousand dollars out of the verdict.

These facts were presented to the judge who presided at the trial, and the defendant's counsel made a motion that the judgment be vacated and a new trial ordered. In granting the motion the court severely criticised the plaintiff's attorney, and in his written opinion stated that he believed that the plaintiff's attorney not only knowingly presented perjured testimony to the court and jury, but actively participated in its manufacture. The indictment of the attorney for the plaintiff by the grand jury followed, and he is now awaiting trial.

Where facts of this character become known or are suspected there is a strong temptation on the part of the defense to look solely to their own convenience and financial interest, and be satisfied with a release, while there are the strongest and most potent reasons on the score of public duty to impel them to go to much inconvenience and some expense in bringing matters of this character to the attention of the criminal, as well as the civil courts, as was done in this case.

The other side of the question we have already suggested, and we infer from investigations that we have made that practices of this sort, especially in some of our Western cities, have resulted in defensive measures on the part of large corporations which are not always compatible with the strictest integrity. There are hangers-on about the court houses in some large cities who seem to be constantly in conversation with the jury panel, and who have no apparent means of livelihood, but who always seem to be flush of money. Coincident with their presence about

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

the court house are stubborn jurymen, who, in cases of clear liability, cause disagreements. The zeal of the adjuster (who is in a way a sort of detective and open to the same sort of temptation that makes a detective's testimony of doubtful value), is in great part to blame.

We regret to notice that the accident departments of some of our large railway companies stir up bad blood and give the attorney for plaintiff good cause for complaint which bears fruit in his justifying himself, to himself if to no one else, in departing from professional ethics. The counsel and the accident adjusters of the railway company should not set up by their conduct a low standard of professional tactics, if for no other reason than because it is bad policy. We refer to the growing practice of settling cases after suit is brought, behind the plaintiff's attorney's back. The counsel for the company excuse themselves to their brethren at the bar by saying that they cannot control their client, the company, and its adjusters —an excuse which, if ever available, certainly is not valid until they have exhausted every effort to compel the company to be as righteous as they desire, and have a right to expect, their opponents to be.

But it is believed, that the loss departments of most of our street railways are run upon the very sound proposition that "Honesty is the best policy." The courts and jurors and the character of the counsel who ordinarily are employed to try the cases for our street railways is so high, that the adjuster who tries trickery or bribery in order to attain success as a shrewd employee must not only fool the court and jury, but must fool the shrewd and honest counsel under whose direction he is supposed to act.

Where any other policy prevails it must in the end arouse such a wave of popular indignation as to be reflected, if nowhere else, certainly in enhanced damages in cases wherein the plaintiffs recover verdicts from indignant juries. H.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

ALABAMA.—Electric Railroads—Injury to Telephone Company—Injunction.

1. While prior occupancy of a street by a telephone company may not confer superior privileges over an electric railway company seeking to construct a line in such street, it may be considered in denial of the latter's usurpation of superior rights in said street.

2. To entitle a telephone company to enjoin an electric railway company from operating a line, under a legislative grant, on a street occupied by the former, damages in the nature of an abuse of the franchise, and not mere incidental damages, must be proved.

3. An electric railway company will be enjoined from erecting its wires in a street in such a manner as to short-circuit the wires of a telephone company, and prevent messages being sent over them, where such damages can be avoided by a proper construction of the line, as such damages would be continuous, and tend to a multiplicity of suits.

4. And for the further reason that a court of equity will interfere to keep such corporations within the line of their authority, and prevent such damages.—(Birmingham Traction Co. vs. Southern Bell Telephone & Telegraph Co., 24 So. Rep., 731.)

ILLINOIS.—Municipal Improvements—Assessment—Property Subject.

1. Under City and Village Act, art. 9, authorizing special assessments for local improvements on property contiguous thereto, the tracks and right of way of a street railroad company in a public street may be assessed for contiguous local improvements therein; and this, even where its franchise is only an easement for a term.

2. Revenue Law (Rev. St. 1893, c. 120), sec. 15, providing that the track, road, or bridge of street railroad companies shall be deemed personal property, and assessed as such in the town or district where located or laid, does not prevent the assessment of the track and right of way of a street railroad for contiguous local improvements.—(Cicero & P. St. Ry. Co. vs. City of Chicago, 52 N. E. Rep., 866.)

ILLINOIS. — Municipal Corporations—Ordinances—Constitutionality—Contracts—Ultra Vires.

1. Under Rev. St. p. 219, sec. 3, providing that a city may permit the construction of a street railway upon such conditions as it deems best for the public interest, a city may require a street railway to pay an annual tax on each mile of its track as a condition to its right to construct and operate its line.

2. It will not be presumed that because an ordinance, authorizing the construction and operation of a street railway, requires the payment of a license fee on each car, that another provision, requiring the payment of an annual tax on each mile of its track, is an improper attempt to raise revenue for the municipal government.

3. An ordinance requiring defendant street railroad to pay an annual tax on each mile of its road, as a condition to its right to construct and operate its line, does not deprive defendant of its property without due process of law, in contravention of the fourteenth amendment to the constitution of the United States and sec. 2 of the bill of rights of the State constitution.

4. An ordinance requiring defendant to pay an annual tax on each mile of its track is not in conflict with Const. art. 4, sec. 22, prohibiting the enactment of special laws where a general law is applicable, though the ordinance applies only to defendant, and not to other street railway companies.

5. Defendant, who accepted a license to construct and operate a street railway, and received its benefits, cannot, as against the city, avoid payment of an annual mileage tax on the ground that the license imposing it was ultra vires of the city.—(Chicago Gen. Ry. Co. vs. City of Chicago, 52 N. E. Rep., 880.)

KENTUCKY.—Taxation of Corporate Franchises—Repeal of Statute—Conclusiveness of Finding of Board of Valuation.

1. Ky. St. secs. 4273-4275, enacted prior to the present constitution, so far as they authorize the board of equalization to equalize assessments upon any other basis than that of the cash value of the property assessed, are in conflict with Const. sec. 172, and Ky. St. sec. 4020, enacted thereunder, and were to that extent repealed thereby.

2. A corporation, whose franchise has been assessed at its fair cash value by the board of valuation and assessment, cannot complain of the inequality caused by the fact that other officers have, in violation of the constitution and statutes, assessed property at less than its fair cash value.

3. The question as to how far the value of the franchise of the corporation is affected by the fact that it is to exist only for a limited time is for the board of valuation and assessment, and its finding as to that matter is final and conclusive.

4. In fixing the value of the franchise of a corporation for assessment, it is proper to deduct the value of the tangible property of the corporation assessed in the State from the value of the capital stock; and, in fixing the value of the capital stock, the board may take into consideration the gross and net earnings of the corporation.—(Louisville Ry. Co. vs. Commonwealth, 49 S. W. Rep., 486.)

NEW YORK.—Conversion—Judgment—Satisfaction—Title of Property.

1. Where the owner of coupons in the possession of another elected to waive their return, and sued as for conversion, and recovered judgment, which was satisfied, the coupons became the property of the wrongdoer.

2.—Evidence—Presumption.—Possession of coupons by the person liable thereon, where there was evidence they were unpaid, raises no presumption that they were received under any agreement preventing the owner from collecting them.

3.—Same—Burden of Proof.—Where, in an action on coupons, plaintiff showed that they had been duly issued by defendant, that plaintiff had become the owner of them, and that they were not paid, the burden was on defendant to show whether any defense existed against the right to recover; and this, though the coupons were in defendant's possession.

4.—Judgment—Notice—Estoppel.—Where the person ultimately liable on coupons was served with notice of the commencement, trial, entry of judgment, and appeal of an action involving their ownership, value, and existence as legal obligations, though not a party, he is concluded as to these issues in a subsequent action on the coupons.

5.—Limitation of Actions—Bonds—Coupons.—Interest coupons of bonds therein described are not outlawed until the bonds are, though they are detached from the bonds.—(Kelly et al. vs. Forty-second St. M. & St. N. Ave. Ry. Co., 55 N. Y. Suppl., 1906.)

NEW YORK.—Bills and Notes—Defenses—Want of Consideration.

1. Where a note was given in settlement of a suit for the infringement of certain patents, apparently valid, and both parties acted in good faith, the maker cannot avoid payment on the ground of want of consideration, because the patents were subsequently adjudged void in another suit.

2.—Same—Payee's Right to Sue.—The fact that the payee of a

note, given in settlement of a pending suit, was not a party thereto, does not affect his right to recover thereon.

3.—Same—Consideration.—A note was given in settlement of a suit for the infringement of patents on electric car equipments to a company not a party to the suit, which also agreed to promptly furnish the maker any trolley equipment it might require. Held, that though the patents were invalid, there was a sufficient consideration for the note moving from the payee in this additional agreement.—(General Electric Co. vs. Nassau Electric R. Co. et al., 55 N. Y. Suppl., 858.)

NEW YORK—Location—Objections by Landowners—Waiver.

1. Railroad Law, secs. 6, 90, provides that a street surface railroad corporation, before constructing its road, shall file a map and profile of the route, and notify occupants of lands over which the route passes; that any occupant may, within fifteen days after notice, apply to a justice of the Supreme Court for relief against the route designated, and alteration of the same; and that the corporation shall not proceed to condemn until the fifteen days have expired, nor until final determination of any application for change of route. Held, that an occupant who fails to object to a proposed route within fifteen days cannot afterwards attack it.

2.—Same—Petition for Condemnation—Sufficiency of Description.—If the center line of a proposed street surface railroad extension is staked out on the ground, or otherwise ascertainable by inspection, without reference to the map of the route, or already known, it is a monument that may be referred to in the "specific description of the property sought to be condemned, and its location by metes and bounds," required by Code, sec. 3360, subd. 2.

3.—Same—Right to Condemn—Agreement with Owner.—Where an adult asserts undivided ownership in land sought to be condemned by a street surface railroad company, and several infants claim an interest therein, and there are liens on the property, the company may resort to condemnation proceedings, under Railroad Law, sec. 90, authorizing that course when the company is "unable to agree" for the purchase of the land.—(Stillwater and M. St. Ry. Co. vs. Slade et al., 55 N. Y. Suppl., 966.)

NEW YORK.—Municipal Corporations—Proceedings to Open Street—Notice.

1. Syracuse City Charter, sec. 167, provides that notice shall be given of the application for the appointment of commissioners to ascertain and report the compensation to be paid to person, owning or having an interest in property proposed to be taken for a street and shown to be benefited. Held, that notice to a mortgagee of a railroad might be dispensed with in a proceeding to take railroad property, where the mortgage is so insignificant in proportion to the value of the road that the lien will not be impaired in the slightest degree by the proceeding.

2.—Same—Statutes—Partial Invalidity.—The fact that said section does not provide, in express terms, that notice shall be given to the owners of property taken and not benefited, does not permit the city to take lands without due process of law, as against owners of lands benefited.—(In re Opening of Oneida St., City of Syracuse vs. Syracuse, B. & N. Y. R. Co., 55 N. Y. Suppl., 959.)

NEW YORK.—Streets—Obligations to Pave.

1. General Railroad Law, sec. 98 (Laws 1890, chap. 565), as amended by Laws 1892, chap. 676, providing that every street surface railroad corporation, so long as it shall use any of its tracks in any street in a city, shall keep in permanent repair that portion of such street between its tracks, the rails of its tracks, and two feet in width outside thereof, as and whenever required by the local authorities to do so, applies to every street surface railroad company, whether incorporated prior or subsequent to the act.

2.—Same—Exemption.—The omission, in a charter of a street railroad company, of a provision compelling it to pave streets along its tracks, does not vest in it or its successors a perpetual exemption from such obligation subsequently imposed by the Legislature under the power given it by Const., art. 8, sec. 1, providing that all general laws creating corporations may be altered from time to time.

3.—Same—Vested Rights.—The term "vested rights" relates to property rights only, and does not embrace an immunity or exemption created by an omission, in a statute incorporating a street surface railway company, to impose a liability on it to pave parts of streets occupied by its tracks.

4.—Same—City Council—Power to Exempt.—A city council has no power to exempt a street railroad company, by contract or otherwise, from the provisions of General Railroad Law, sec. 98, as amended by laws 1892, chap. 676, requiring all street surface railroads to pave certain portions of streets occupied by their tracks.

5.—Same—Exemption Contract—Legalizing Statute—Constitutionality.—Laws 1893, chap. 231, legalizing a contract between the city of Binghamton and the Binghamton Railroad Company exempting it from part of the provisions of General Railroad Law, sec. 98, as amended by Laws 1892, chap. 676, requiring it to pave certain portions of streets occupied by it, is not void as a grant to the company of an "exclusive immunity" forbidden by the constitution.

6.—Same—Repeal.—Nor was such legalizing act repealed by implication by Laws 1893, chap. 434, sec. 90, passed a month thereafter, providing that the general law requiring street railroad companies to pave certain portions of streets along their tracks shall apply to every corporation, however organized; nor by Laws 1895, chap. 933, which, in amending the general railroad law in other unrelated respects, necessarily re-enacted section 90.

7.—Same—Validity.—Laws 1893, chap. 231, legalizing a contract between the city of Binghamton and the Binghamton Railroad Company, exempting the latter from liability to pave parts of streets occupied by it, was not void because it validated a contract void for want of power in the city to make it, since the Legislature may confer such power by retrospective legislation.—(Wood vs. Common Council of City of Binghamton et al., 56 N. Y. Suppl., 105.)

SOUTH CAROLINA.—Municipal Corporations—Laying Railroad Tracks in Street—Consent of Abutters—Condemnation.

Under Acts 1894, p. 1002, sec. 14, authorizing the town council of Gaffney City to close up, widen, or alter a street by condemnation in case the abutters refuse consent, the council has no authority to permit a railroad to lay its tracks in a street, where consent was refused, without condemnation and compensation.—(Wilkins et al. vs. Town Council of Gaffney City et al., 32 S. E. Rep., 299.)

TEXAS.—Municipal Corporations—Change in Grade of Streets—Delegation of Authority—Liability to Abutters—Council—Proceedings—Committees—Joint Tort Feasors—Evidence—Instructions.

1. Where a railroad company raises the grade of a street through a contractor, pursuant to authority granted to it or to the contractor by a city acting under the power conferred by charter to alter the grade of streets, the city alone is liable to an abutter for damages resulting from the change.

2. An alderman testified without objection that he gave a railroad company authority to change the grade of a street, "for the council recommended it," and that he "suggested the matter to the council, but *could* not state how the vote stood there." Held, that the question whether the council authorized the change was for the jury.

3. The necessity of submitting the question to the jury was presented by a request to charge the erroneous proposition that such authority might be given without a formal order passed by the council in session.

4. A street committee of a city council has no authority to authorize a railroad company to change the grade of a street, unless conferred by charter or by the council.

5. Where a railroad company raised the grade of a street through a contractor without authority from the city, and the contractor authorized the engineer of the company to specify where the dirt should be placed, and the engineer gave directions thereunder, the company and the contractor were not joint tort feasors, so as to preclude the latter from recovering over against the former in an action by an abutter for damages.

6. The Denison City Charter provides that the council shall hold regular meetings; that its voice shall be ascertained by vote; and that the city secretary shall attend every meeting, and keep accurate minutes of the proceedings, and record votes. Held, that authority to change the grade of streets, which is conferred on the council by charter, cannot be granted by the consent of each member of the council individually. The council must act as such.—(Denison & P. Suburban Ry. Co. vs. James et al., 49 S. W. Rep., 660.)

LIABILITY FOR NEGLIGENCE.

ILLINOIS.—Contributory Negligence — Instructions — Error Cured—Damages—Pleading.

1. Where plaintiff did not begin to alight from defendant's car until it had stopped, and when it stopped she was holding on with both hands, and had one foot to the ground, and the car jerked after she put the foot on the ground, and before she had time to lift the other foot, she exercised ordinary care.

2. If an instruction that if plaintiff, while alighting from defendant's car, was using reasonable care, and defendant negligently caused the car to be set in motion, and plaintiff was thereby injured, the jury should find defendant guilty, is objectionable in omitting the question whether the negligence of plaintiff was the proximate cause of the injury, the objection is obviated by a subsequent instruction that, if plaintiff was negligent in alighting, and such negligence was the cause of the injury, a verdict of not guilty should be returned.

3. If such instruction is objectionable in not defining "reasonable care," the objection is obviated by a subsequent instruction

that a person attempting to alight from a street car is bound to use ordinary care to avoid injury, under any and all circumstances, and if she fails to use such care, and is injured by reason thereof, she cannot recover.

4. In an action for personal injuries, a recovery for any disability rendering plaintiff less capable of attending to her business may be had without an averment of special damage, where plaintiff is a common laborer, since the damages necessarily result from the injury.—(North Chicago St. R. Co. vs. Brown, 52 N. E. Rep., 864.)

INDIANA.—Special Verdict—Objections—Injuries to Trespassers—Constitutional Law—Title of Act—Jury Trial.

1. The question of the validity of a special verdict is not raised by an objection to the filing of defendant's request for a special verdict, where no demand was made that the jury be directed to bring in a general verdict, and no objection was made on the return of the special verdict, nor any request that the jury be sent back with instructions to make a general verdict.

2. Where a boy, being unable to get on an open electric car, stands upon the side of the car, on which strips extend to prevent the egress or ingress of passengers, placing his foot on the boxing of the axle, and rides thereon for some distance without paying a fare or offering to do so, and without being asked for his fare, he not being seen by any employee of the railroad company, though he had money in his pocket with which to pay such fare, if asked for it, and falls off and is run over by the wheels of the trailer, the railroad company is not liable for injuries received, the place where the boy was riding being very dangerous.

3. Plaintiff, while so riding, was not a passenger to whom the carrier owed a safe carriage and immunity from injury.

4. The fact that plaintiff was a child about nine years old did not make him less a trespasser on the car, if the other facts compelled the conclusion that he was wrongfully on the car.

5. Act March 11, 1895, amending the practice act, and providing for special verdicts, sufficiently expresses the subject in the title, "An act to amend section 389 of an act concerning proceedings in civil cases, approved April 7, 1881, and designated as section 546 of the Revised Statutes of 1881."

6. Act March 11, 1895, providing for special verdicts, which act, except as to form, did not change the law governing special verdicts as it had existed in the State since 1852, is not unconstitutional, as violating the right of trial by jury.

7. Where an application for a special verdict is made under Act March 11, 1895, and 144 interrogatories are submitted to the jury, covering every material fact, exclusion of others tendered, calling for mere opinions and for conclusions of law, was proper.

8. Where a special verdict is requested, no instructions are proper, except such as are necessary to inform the jury as to the issues, the rules for weighing evidence, who has the burden of proof, and whatever else may be necessary to enable the jury clearly to understand its duties.—(Udell vs. Citizens St. Ry. Co., 52 N. E. Rep., 799.)

INDIANA.—Defective Street—Duty to Repair—Special Finding—Presumption—Contributory Negligence—Instructions—Review.

1. It cannot be presumed that a person injured did not exercise any care, from a special finding that the evidence did not show "what care" he was using when the injury occurred.

2. In the absence of knowledge to the contrary, one driving over a street is entitled to presume that it is in a reasonably safe condition for travel.

3. One injured by reason of a defective street, which he knows to be unsafe, is not guilty of contributory negligence, if he uses care proportionate to the known danger.

4. On an issue as to what would constitute constructive notice of a defect in a street, the court charged that a very short time might be sufficient, considering the location, character, and permanence of the defect, "and such other things as throw light on the question," and added that what the facts were and the interferences to be drawn therefrom were for the jury to determine, under all the evidence and circumstances. Held, in view of the closing clause, that the instruction was not erroneous, as authorizing the jury to consider facts not shown by the evidence.

5. Since a street railroad company is bound to so maintain its tracks as not to impair the safe condition of the street, whether required by ordinance or not, an instruction that, if a street railway company accepted an ordinance imposing such obligations, a violation thereof rendering the street dangerous would be negligence, which, if the proximate cause of another's death, who was exercising due care at the time, would render the company liable therefor, was not error.

6. A verdict of a jury cannot be disturbed on appeal where there is some evidence to support it.

7. It is not error to refuse requested instructions covered by those given.—(Citizens St. Ry. Co. et al. vs. Ballard, 52 N. E. Rep., 729.)

LOUISIANA.—Contributory Negligence—Infants—Motoneer—Damages—Personal Injuries.

1. A plaintiff's act or omission, when only a remote cause, or a mere antecedent occasion or condition, of the injury inflicted, is considered not to be contributory negligence.

2. A child of three and one-half years is, of itself, incapable of contributory negligence.

3. No man should be in charge of an electric car as motoneer, running along populous thoroughfares of a city, who has not the full and complete use and sight of both eyes.

4. No doctrine or rule exists here that the negligence or imprudence of a plaintiff, while not of the proximate character to defeat his recovery, may yet be looked to by the jury or court in mitigation of damages.

5. Nevertheless, this court has constantly exercised its reasonable discretion of increasing or diminishing the sums awarded for damages, according to its judgment, operating on the facts, prompted in given cases.

6. It has never been the intention to fix by rule specific sums for different classes of injuries, nor for varying grades and duration of anguish and suffering.

7. In this respect, each case is considered independently, on its merits, and on the state of facts peculiar to it, a due regard, however, being always had to the proper observance of a reasonable uniformity of jurisprudence on general lines.—(Rice et ux vs. Crescent City R. Co., 24 So. Rep., 791.)

LOUISIANA.—Injury to Passenger—Contributory Negligence.

1. The West End passenger train of the defendant company came to its stopping place on Canal Street, where it was when plaintiff walked up to the train, and turned to the right, in order to board the smoking car at the end of the train. An electric car of the defendant company ran on its track, which was near the steam train. The projection of the electric car and the projection of the steam train (toward each other) made very narrow the path upon which plaintiff was walking, with his back to the electric car, by which he was knocked down, and greatly injured. The rule as to looking and listening had no application. About midday, defendant's motorman did not see plaintiff, who was walking in front, in a dangerous position, because of his advancing car. It was his duty to keep a sharp lookout, and see pedestrians at the place on their way to board the cars. No gong was sounded, and no alarm.

2. There was no proper care on the part of the employee in charge of the defendant's electric car. Such care and diligence must be exercised at dangerous places on a railway, to avoid inflicting injury, as the proper manning of a car requires.—(Conway vs. New Orleans City & Lake R. Co., 24 So. Rep., 780.)

MASSACHUSETTS.—Liability for Injuries—Acts of Fellow Passengers—Knowledge of Passenger's Infirmity.

1. A carrier is not liable to a passenger for injuries received by the fall of another passenger, who was jostled by the conductor while removing a drunken passenger from the car in the exercise of due care.

2. Where a passenger was injured through the carrier's attempt to remove a drunken passenger from the car, the carrier, if liable at all, was liable only for the consequences of the injury, and not for any fright or other injury suffered by the passenger through the drunken man's presence, or the attempt to remove him.

3. The conductor's knowledge of a passenger's infirmities does not increase the carrier's obligations to her.

4. A carrier whose servants committed a battery on a passenger is liable for all damages sustained by him, even though the injury to a normal person would have been less.—(Spade vs. Lynn & B. R. R., 52 N. E. Rep., 747.)

NEW YORK.—Negligence of Driver.—The failure of the driver of a horse car to observe a boy when he slipped on the track, on a dark night, four feet in front of the horses, at a part of the road not a crossing, does not justify an inference of negligence.—(De Ioia vs. Metropolitan St. Ry. Co., 56 N. Y. Suppl., 22.)

NEW YORK.—Injury to Person Near Track—Question for Jury.—Evidence showed that plaintiff was standing on a crosswalk between the tracks of a street railway, preparatory to taking a south bound car, when he was struck by a north bound car, which was in full view of him while approaching. The drivers were instructed to slow up or stop when approaching a car near or on a crosswalk receiving passengers, but the driver of the north bound car approached the place where plaintiff was standing, without checking his speed. Plaintiff, being about to take the south bound car, was facing in that direction, and did not notice the approach of the other car. Held, sufficient to authorize the submission of the case to the jury.—(Boentgen vs. New York & H. R. Co., 55 N. Y. Suppl., 847.)

Arguments Against the Vestibuling of Cars.

The following interesting letter was addressed by John W. McNamara, general manager of the Albany Railway, to the committee of railroads of the New York State Assembly, arguing against the passage of several bills pending before the railroad committee in relation to vestibuling or inclosing platforms of cars of street railways:

To the Honorable Committee of Railroads of the Assembly:

Gentlemen.—The Albany Railway respectfully opposes the passage of any of the proposed measures providing for the vestibuling or inclosing platforms of its cars, for the following reasons:

I. The Appellate Courts of the several States of the United States and the Supreme Court of the United States have laid down the law in relation to the care to be exercised by persons or corporations operating street railways. According to the several decisions, the operator of a street car, especially if it is impelled by cable or electric power, is bound to keep a constant watch for persons and vehicles on the street, and although he is not bound to anticipate that foot passengers will attempt to cross otherwise than at regular crossings, and he, therefore, need not maintain quite the same degree of vigilance, he is always held responsible for failing to see even persons crossing at other places if he would have seen them had he been in the exercise of ordinary care.—Sherman and Redfield on Negligence (5th ed.), section 485c.

1. This being the law, street railway managers are obliged to select able-bodied, competent operators of their cars. The operator must be able-bodied, and physically able to promptly control all the appliances usually on cars for the purpose of starting and stopping them. His eyesight must be good, so that he may be able to see obstructions on the track, or at points along the line see those who are about to cross the track. His hearing must be good, so that he may be able to hear all signals given to him by the conductor and promptly obey them; and the warnings and signals of pedestrians or persons desiring to board cars. He must be able to speak, and preferably to speak the English language. His habits must be good. No one known to habitually use intoxicating liquors can legally be employed as the operator of a car.—Railroad Law, section 42, and Liquor Tax Law, section 41. Penal Code, section 420.

II. The law requiring the utmost vigilance on the part of those operating street railways is being constantly enforced by the courts in actions brought by persons suffering damages either to person or property. It would seem, therefore, unjust to require street railways, first, to take the greatest care in the selection of the operators of its cars and the greatest vigilance on their part, and then, second, to compel them to place such operator in such position that having ears he cannot hear, having eyes he cannot see, and having a tongue and voice he cannot use them. That is just what each one of the bills we are considering requires street railways to do. It requires the operator to be inclosed in a vestibule, so that his ability to see and hear and make himself heard is abridged.

1 As cars are now operated in Albany, the operator is in a position where he can be seen by all persons traveling on the street; where he himself can see all persons who are crossing, or attempting to cross, the track upon which he is driving his car; and he is in a position to hear warnings given to him by others; and is also in a position to give warning himself to those who may inadvertently place themselves in danger.

2. It is not saying too much to say that hundreds of persons have been saved from serious injury by reason of the ability of the operators of the cars of the Albany Railway to make themselves heard.

III. The experience of electric railways and other railways using vestibules is that the vision of the operator is very much obscured, and the percentage of accidents happening by reason of this interference with vision is consequently larger.

1. It is impossible to keep the glass portion of the vestibule clear in cold, foggy or stormy weather. It is found at night that in order to enable the operator of the car to see at all, it is necessary to cover the front part or front windows of the car proper with a curtain. The effect of this, of course, is to prevent the passengers riding in the car from seeing the operator. For aught they know, he may have been taken with a fit and be lying senseless on the platform.

2. The hearing of the operator of a car while inclosed in a vestibule is very much impaired by reason of the resonating effect of the vestibule. All the noise made by motors and wheels on the track seems to be concentrated and intensified in the vestibule.

3. The conductor of the car, who occupies the rear part, is handicapped by the vestibule. If the trolley goes off, which is quite a common occurrence on all overhead trolley roads, it is necessary for him to get off the car to put the trolley on.

4. The present platforms enable persons to see the conduct of the driver, both from the inside of the car and from the outside of the car, during an impending accident. Many an operator of a car has been able to prove his great vigilance by aid of the testimony of persons standing on the sidewalks or sitting in the car which he was operating, when, if he had been inclosed in a vestibule, as these bills propose to inclose him, it would be impossible for him to do so.

5. The motion of his hands in throwing off power and putting on brakes is plainly visible. If he were inclosed in a vestibule, no one would be able to see whether he made any effort to stop the car or not.

6. The open platform enables inspectors of operation to readily see the position and condition of the operator.

IV. Unless, therefore, the Legislature is prepared to relax the rule of law established by the courts, and give the operators of street railways the same right to operate their cars as is now enjoyed by steam railroads, they, the railways, should be permitted to manage the operation of their cars in such a way as to secure the least possible damage to the persons and property of others.

V. The reason given by the proponents of the several bills for their passage, namely, their sympathy for those engaged in operating cars, does not take into account the much larger number of persons interested in preserving their lives. For instance, the number of operators of cars employed by the Albany Railway does not exceed one hundred and fifty, while the population of the cities through which the cars of the Albany Railway are operated exceeds two hundred thousand. It is, therefore, a question whether it is better to conserve the health and comfort of one hundred and fifty persons who may be exposed to wind and storm for a few days in each year, or to jeopardize the limbs and lives of thousands of people who have occasion to use the streets through which the cars run.

1. The Albany Railway and the Watervliet Turnpike and Railroad Company have operated street railway cars in the city of Albany and vicinity since 1863. During that time there is no record that any operator of either a horse or an electric car contracted any disease while operating such cars which caused his death or hastened his death. The fact is that the drivers of cars are among the healthiest of the employees of a street railway.

2. The lives of persons run down by street railway cars are as precious to their fathers and mothers, or, in the case of parents, to their children, as the lives of the operators of street cars are to those who are related to them. With all the care which it is possible now to exercise, many annually lose their lives by reason of being struck or run over by street cars. It would seem, therefore, that any legislation which tends to increase the number who thus annually lose their lives should be restrained and withheld.

3. It is well known that pedestrians and drivers of vehicles on streets through which street railways are operated rely upon the vigilance of the operators of street cars to warn them of the approach of the car, and to stop the car if necessary to prevent a collision or accident.

4. A car with a human being in plain sight on an open platform seems less like an engine of destruction than a car with an inclosed platform, the operator of which is concealed from those using the streets as pedestrians or drivers of vehicles.

VI. The fact that the operators of street cars—motormen and gripmen—want vestibules; or the fact that corporations owning railways do not want them, should not influence the decision of the question.

1. Many who advocate the vestibuling of cars do so simply from the standpoint of sympathy for the operator of the car. All other considerations are ignored or forgotten.

2. It is barely possible that some operators of cars may desire vestibules, forgetting for the moment how a vestibule would handicap them in the operation of their cars.

VII. The question, therefore, whether any of the bills providing for the vestibuling of cars, or the modification of any of them, should be reported by your committee is respectfully submitted to you for consideration on all the facts which have been laid before you.

Dated March 2, 1899.

A subscriber to the Street Railway Journal wishes to purchase about 450 horses.

Annual Reports

ATLANTA CONSOLIDATED STREET RAILWAY COMPANY, ATLANTA, GA.

The report of this company for the year ending Dec. 31, 1898, is as follows:

Receipts from passengers	$404,529
Receipts from other sources	3,868
Total receipts	$408,397
Operating expenses	222,441
Earnings from operation	$185,956
Deductions from Earnings.	
Interest	$108,682
Taxes	10,433
Net income	$66,841
Per cent, operating expenses to total receipts	52.4

Balance Sheet. Dated Dec. 31, 1898.

Assets.		Liabilities.	
Plant	$4,446,380	Capital stock	$2,000,000
Cash	232,623	Funded debt	2,250,000
Material on hand	15,066	Bills audited	14,930
Unearned insurance	715	Suspense	6,800
Bills receivable	758	Pay rolls	10,439
		Dividend	904
		Profit and loss (surplus)	412,468
Total	$4,695,542	Total	$4,695,542

INTERURBAN ROADS.

The following annual reports of five of the leading interurban roads in the country will be of interest:

TWIN CITY RAPID TRANSIT COMPANY, MINNEAPOLIS, MINN.

Year Ending Dec. 31, 1898.

Receipts from passengers	$2,145,093
Receipts from other sources	25,623
Total receipts	2,170,716
Operating expenses	1,019,392
Earnings from operation	$1,151,324
Deductions from Earnings.	
Interest on funded debt, and dividends on preferred stock	$713,454
Taxes	64,214
Net income	$373,656
Per cent, operating expenses to total receipts	46.96

CINCINNATI, NEWPORT & COVINGTON RAILWAY COMPANY, CINCINNATI, OHIO

Year Ending Dec. 31, 1898.

Gross receipts	$681,672
Operating expenses	302,201
Earnings from operation	$379,471
Fixed charges	318,144
Net income	$61,327
Per cent, operating expenses to total receipts	44.3

CLEVELAND, PAINESVILLE & EASTERN RAILROAD COMPANY, CLEVELAND, OHIO

Year Ending Dec. 31, 1898.

Gross receipts	$105,360
Operating expenses	58,880
Earnings from operation	$46,480
Interest	25,000
Net income	$21,480
Per cent, operating expenses to total receipts	55.8

LORAIN & CLEVELAND RAILWAY COMPANY, CLEVELAND, O.

Year Ending Dec. 31, 1898.

Gross receipts	$73,037
Operating expenses	33,665
Earnings from operation	$39,372
Interest	35,000
Net income	$4,372
Per cent, operating expenses to total receipts	46.

AKRON, BEDFORD & CLEVELAND RAILROAD COMPANY, CLEVELAND, OHIO

Year Ending Dec. 31, 1898.

Gross receipts	$96,054
Operating expenses	65,171
Earnings from operation	$30,883
Interest	19,221
Net income	$11,662
Per cent, operating expenses to total receipts	67.8

QUARTERLY REPORT OF BROOKLYN HEIGHTS RAILROAD COMPANY, BROOKLYN, N. Y.

Quarter Ending Dec. 31.

	1897.	1898.
Receipts from passengers	$1,297,346	$1,439,848
Receipts from other sources	66,203	20,558
Total receipts	1,363,549	1,460,406
Operating expenses	766,538	886,579
Earnings from operation	$597,011	$573,827
Fixed charges	569,108	535,002
Net income	$27,903	$38,825

Change in Brooklyn, N. Y.

The Brooklyn Rapid Transit Company has secured control of the Brooklyn Union Elevated Railroad, formerly the Brooklyn Elevated Railroad Company. It is stated that transfers will be given to passengers from the surface cars to the elevated trains, and also that the elevated will be equipped with electricity in the near future. The property of the Brooklyn & Brighton Beach Railroad Company has also been recently purchased by the Brooklyn Rapid Transit Company, and it is reported that the purchase of the Kings County Elevated Railroad will soon be consummated.

Changes on the Manhattan Elevated Railway

It has been officially announced by the directors of the Manhattan Elevated Railway Company, of New York, that the third rail system will be employed when the road is equipped with electricity. In addition to the changes in officers mentioned in the last issue of the Street Railway Journal, L. B. Stillwell has been appointed consulting electrical engineer for the company. Mr. Stillwell has been for about six years in charge of the electrical plant of the Niagara Falls Power Company at Niagara Falls, N. Y.

NEWS OF THE MONTH

The South Bend Street Railway Company, of South Bend, Ind., was fined recently for placing salt upon its tracks to clear them of snow and ice. It is claimed this was in violation of a city ordinance.

A curious accident happened on March 19 on the electric railway at Yarmouth, N. S. In order to clear the tracks of snow and ice two motor cars were started, one immediately behind the other and touching, but not coupled. While proceeding in this way under full power, the bumper of the rear car in some way got under the back bumper of the front car and lifted it. Immediately the front car left the track at an angle on a slight declivity, and rushed at full speed onto the sidewalk and part way into a brick building, tearing away a heavy iron pillar and considerably damaging the contents of the building. There were no passengers on the car at the time.

A bill has been introduced in the Missouri Legislature prohibiting the municipal authorities of cities in that state from granting franchises for constructing street railways along the streets of cities except upon petition of the people owning one-half of the frontage along such streets.

The consummation of the consolidation of all the street railways in Buffalo and vicinity was effected on March 22. A new company, to be known as the International Traction Company, has been formed, and it is stated a new mortgage for $30,000,000 will be issued. J. P. Morgan & Co., of New York city, are the prime movers in the deal. The companies affected by the consolidation are as follows: The Buffalo Railway Company, the Buffalo Traction Company, the Buffalo, Bellevue & Lancaster Railway Company, the Buffalo & Niagara Falls Electric Railway Company, the Buffalo & Lockport Railway Company, the Niagara Falls Park & River Electric Railway Company, the Niagara Falls & Clifton Bridge Company and the Lewiston & Queenstown Heights Bridge Company. It is stated that the Buffalo Railway stock was purchased for $100 per share, the Buffalo & Niagara Falls at $75, and the Buffalo & Lockport at $50.

The Joliet Street Railway Company, of Joliet, Ill., has voluntarily increased the wages of all its employees 10 per cent. The action was taken as the business of the company has rapidly increased and the prospects for the coming year are better than ever before.

One of the best examples of rapid and healthy growth of a street railway system is given in the case of the Milwaukee Electric Railway & Light Company. The management of this property have made their plans on broad lines, and the result is that tracks have either actually been constructed or franchises have been secured for making one of the finest interurban systems in the country, with cars running in and connecting all the prosperous manufacturing towns along the lake between Milwaukee and Chicago.

A large brewing company has recently been incorporated at St. Louis and will immediately proceed to the erection of an extensive brewing plant. Among the schemes included in this new organization is the running of electric refrigerator cars upon the street railway system, thus doing away with heavy hauling wagons.

The employees of the Keokuk Street Railway & Power Company, of Keokuk, Ia., went on strike recently, owing to a new order requiring them to work longer hours at the same rate of pay.

The management of the New York & Queens County Railway Company, of Long Island City, has decided to adopt the service stripe system for its employees. There is some discussion among the men as to whether they prefer stripes on their sleeves or brass buttons to mark the years of service.

On Wednesday evening, March 15, Alexander Wurts, of the Westinghouse Company, delivered a lecture on lightning arresters before the Cleveland Electric Club, at the Electricity Building of the Case School of Applied Science. The lecture being a popular one, the hall was well filled with an appreciative audience. Mr. Wurts spoke of the decadence of the lightning rod as a means of building protection, and said that they were now rarely found except on very old buildings, or on a few very high buildings or towers, like the Capitol at Washington and the Washington Monument. The lecture was illustrated by practical experiments, and showed in detail the steps that led up to the use of non-arcing metal in the construction of lightning arresters, or lightning diverters, as the lecturer said they should more properly be called.

The Cleveland Electric Railway Company has let the contract for a funeral car, which will be rented for $10, and will be run over any line in the city. The car will be divided into two compartments, one for the coffin and the other for the mourners.

The postmaster at Hartford, Conn., has devised a street railway mail box, which will be used experimentally on the lines in that city. The box is strongly made of cast-iron, and is attached to the rear dasher in such a way that letters may be dropped therein whenever the car stops. It is thought that this system, if adopted, will greatly reduce the time of delivery of letters addressed to local points.

The meeting of the Franklin Institute at Philadelphia on March 28 was devoted to the subject of electric railways. The following papers were discussed: "The Multiple Unit System of Electric Railways," presented by Frank J. Sprague; "The Electric Inspection of Street Car Equipments," by Albert B. Herrick; and "Some of the Larger Transportation Problems in Cities," by Edward E. Higgins, editor of the Street Railway Journal.

The Cincinnati & Hamilton Electric Street Railway Company, of Hamilton, Ohio, has published a neat descriptive folder and time table of its lines between Hamilton and College Hill, Cincinnati. The pleasures of a trip over this road are told in an interesting manner, and a number of points of interest along the line are briefly mentioned. The folder contains a number of advertisements of local firms.

In the course of a recent conversation with a prominent supply man, he stated that the water from the Chicago River contained less scale-forming ingredients than any other water he ever saw used for steam boiler purposes.

A curious incident occurred in the final transaction completing the filing of the mortgage of the United Railways & Electric Company, of Baltimore. The mortgage is for $38,000,000, and about $25,000 internal revenue stamps had to be attached to the original copy. The revenue officer at Baltimore was unable to supply the stamps and had to secure an extra supply. The mortgage was printed in pamphlet form, with every other page blank, and the revenue stamps covered half of the blank pages and the margins of half of the printed pages.

The Meadville Traction Company of Meadville, Pa., has just commenced the erection of a large pavilion and summer theater at its Oakwood Park. The pavilion will be 136 ft. x 74 ft., and two stories high. It will have an iron truss roof, arched at the center, with a tower at each corner of the building. Verandas 12 ft. wide will surround the entire building at both stories. The theater will be on the ground floor, and will be 100 ft. x 50 ft. The theater will be tastefully finished with comfortable seats and everything necessary to make it pleasant and attractive. A ballroom 100 ft. x 50 ft. will be built on the second floor, and the ceiling of the theater and floor of the ballroom will be supported by separate sets of joists, so that the progress of a ball will in no way interfere with the play or opera. The balance of the building not occupied by the theater and ballroom will be taken up with offices and reception rooms.

The Brooklyn Heights Railroad Company is considering the advisability of making two rates of fare from the bridge to Coney Island. It is thought that a great many people would prefer to pay ten cents fare and avoid the large crowds going to the beach on pleasant days, and the company is therefore thinking of introducing a ten-cent fare in addition to the five-cent service.

The city officials of Syracuse, N. Y., and the managers of the Syracuse Rapid Transit Railway Company have not been on very good terms of late. The city made a number of demands which the company refused to consider. The Mayor then gave notice that he would enforce every ordinance touching the speed of the cars and their sanitary condition, and would bring into effect many laws which have for a long time been considered dead letters. On the evening of March 26 there was a snowfall of over 6 ins. at Syracuse, and this gave the Mayor an unlooked-for opportunity. The next morning the company had out its snowplows and pushed the snow from the tracks, piling it up along the street beside the tracks to a considerable height. An old ordinance states that snow shall be carted away, and as this was not done the commissioner of public works was ordered to get out his men and shovel the snow back on the tracks. So effectually was this carried out that in less than an hour after the order was issued almost the entire system was tied up.

Street Railway Accountants Association

The next annual convention of this association will be held simultaneously with, and in the same building as the meeting of the American Street Railway Association, at Chicago, Oct 17-20 Papers will be read on the following important subjects: "Car Mileage," "Blanks and Forms," "Materials and Supplies Accounts," "What Does the General Manager Want to Know from the Accounting Department?"

The secretary of the association has recently received the following letter showing that the department of blanks and forms has become a reality and is appreciated. The letter reads: "I am sending you to-day by express the blanks loaned to this company by the department of blanks, and I desire to say I am most gratified as I found among the blanks sent me precisely the ideas for which I had need."

A New Foundry at Schenectady

The great Schenectady (N. Y.) works of the General Electric Company have been constantly expanding from year to year with a steady increase in the company's business, and the pressure upon these shops has been such that hardly had the new extensions been completed before their increased capacity has been reached and it has been proven that the total requirements have again been underestimated. The latest addition to the works is an immense foundry, which was opened for work on Jan. 5 last, after a period of construction extending over about ten months. Large as this foundry is, and however confidently it was expected to fulfill the company's requirements for some years to come, it is, even so soon, worked to nearly its full capacity many days, and the prospects for extensions within a year to come seem good.

As many novel and interesting features have been included in this new building, a somewhat detailed description of it and of its equipment will be of interest to manufacturers and to such street railway companies as are doing their own repair work on a large scale.

The immense main building in which the melting, moulding and pouring are done in undivided space is 140 ft. x 503 ft. Separated from this building is the cleaning room wing, 120 ft. x 103 ft., in which all the cleaning and drying of castings is done. By having this cleaning done away from the main foundry, the possibility that flying chips and dust may reach the moulds and interfere with perfect castings is avoided. Exhaust rumblers are provided for carrying all dust outside the buildings, and there are complete arrangements for opening windows and ventilators in the monitor so as to thoroughly clear out the atmosphere. The result is that there is very little of the characteristic "foundry smell" in the building. Also attached to the main building is a large lean-to 38½ ft. x 243 ft., and a small lean-to 11ft. x 152 ft. The height of the side walls is nearly 24 ft. and of the main gables 58 ft. The entire structure contains 3,250,000 cu. ft. of air space.

The most prominent characteristic of the foundry is the magnificent light obtained in all sections through the large area of skylight surface, namely, 23,336 sq. ft. It was determined to depart from the usual practice of dark and dingy foundries and to avoid the use of artificial light as much as possible. The skylights are composed of glass mounted around wire netting in such a way as to make breakage difficult, and the dropping of glass from the netting, even in case of breakage, practically impossible. The glass is also lightly ribbed to secure better diffusion of light. For artificial lighting, one arc light is provided for every 2600 ft. of floor space, and this makes good night work entirely possible.

The transportation facilities within the building are unusually perfect. Tracks are laid through the main and many of the side aisles, and tram cars can pass to almost any part of the floor, conveying supplies of all kinds, such as sand, coke, pig iron, scrap iron and the smaller castings. Two immense electric cranes span the center aisle, and five others operate in the building, while eventually there will be six jib cranes put in position for local work, and portable jib cranes will also be used.

The equipment of the foundry consists of the following apparatus:

Three Calliau cupolas of 18, 11 and 7 tons melting capacity per hour, respectively.

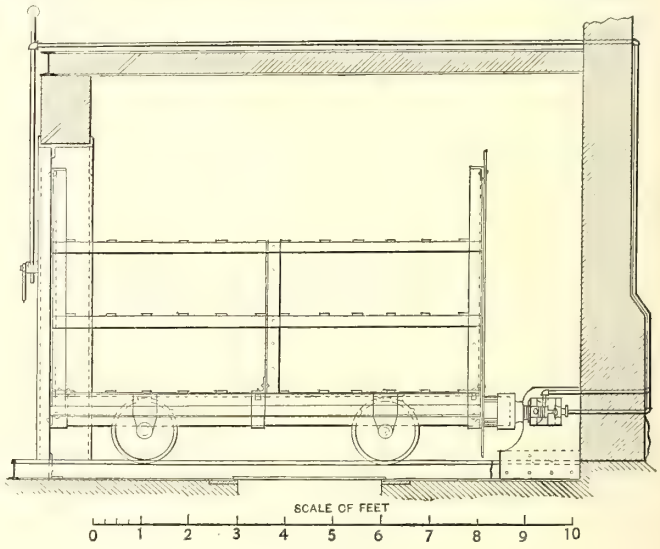
Seven ladles of 15, 10, 6, 4, 3½, 2, 1½ tons capacity, respectively

One Root blower, capacity 660,000 cu. ft. of air per hour at 95 r.p.m.

Nine exhaust rumblers.

One Buffalo Forge Company heating fan, blast wheel (steam coils 27,500 sq. ft. surface), 14 ft. diameter x 6 ft. wide.

One Buffalo Forge Company heating fan, blast wheel 14 ft. diameter x 7 ft. wide.



One 2200 lbs. hydraulic elevator.
One Sellers sand mixer.
One 10-ton Fairbanks' scales.
One 40-ton Morgan crane, 65 ft. span.
One 10-ton Morgan crane, 65 ft. span.
One 10-ton Morgan crane, 47 ft. 2 ins. span.
One 7-ton Box crane, 32 ft. span.
Three 5-ton Box cranes, 32 ft. span.
Three 5-ton jib cranes, 21 ft. swing.

ELECTRIC MOTORS

One 60 h.p. for cupola blower.
Two 35 h.p. for heating fans.
One 50-h.p. for rumblers and wheels.
One 7 h.p. for cupola rumbler.
One 7 h.p. for flask making.
One 3 h.p. I. B. for sand mixer.
One C. P. 10, for air compressor.
One G. E. 51, for 40-ton crane.
Two G. E. 52, for 40-ton crane.
One 5 h.p. I. B. for 40-ton crane.
Two G. E. 52, for 10-ton cranes.
One 5 h.p. I. B. for 10-ton cranes.
Four L. W. P. 5, for 5-ton and 7-ton cranes.
Four 3 h.p. I. B. for 5-ton and 7-ton cranes.
Three L. W. P. 5, for jib cranes
One 5 h.p. I. B. for coke conveyor.

The loading floor of the cupolas in the cupola room is large enough to make room for an ample quantity of coke, pig and scrap iron, which is brought from the yards, weighed on the lower floor and conveyed to the loading floor by an elevator. All the small work done in the foundry is carried around in cupolas, the object being to avoid the necessity of carrying small ladles by hand for any great distance. The larger ladles are conveyed by electric cranes to the more distant portions of the shop.

The core ovens of the foundry are unique in that through special

CORE OVEN

methods, their capacity is hardly one-quarter that ordinarily required for a foundry of this size. The ovens are kept at the baking temperature day and night, and the process of baking can be carried on at all hours instead of, as usual, at night. This is accomplished as follows: There are four large doorways to the core ovens. Through these pass tracks which end outside a few feet away from the oven. Over these tracks passes a car containing shelves or racks, on which the cores are placed ready for baking. This car terminates at each end in a large door which completely fills the opening in the core oven so that when the car is inside the oven, one of its ends closes the opening, and one is outside the other end. In this way the only chance for the escape of the hot air of the oven is in the short time when the car is passing in and out. These cars are worked by compressed air and the operation of moving in and out is very rapidly accomplished.

The foreman's office is elevated and is so located as to command the entire floor of the main building, so that the entire operations of the foundry are in plain sight. There are extensive lavatories in one of the wings of the foundry, provided with shower baths, basins and wire lockers, one for each workman. Altogether, this is one of the most complete and perfectly appointed foundries in existence to-day.

The structural iron for this foundry was supplied by the Hilton Bridge Construction Company, of Albany, N. Y.

Report of the Glasgow Corporation Tramways

The following report on the proposed power station and methods of distributing electrical energy was submitted under date of Feb. 28, 1899, by H. F. Parshall to the sub-committee on traction and works of the Glasgow Corporation tramways committee

REPORT.

Complying with your request of Feb. 6, I have studied the conditions under which the Glasgow tramways have to be worked, and beg to submit the following report as to the most efficient and economical method of generating and distributing electricity for the overhead trolley system of electric traction:

1. Increase of Traffic with Electric Traction.—You are at present working in Glasgow 380 cars by horse and 27 by electric traction. Having reference to your proposed extensions and the usual growth accompanying the conversion of horse traction systems into electric traction systems, 600 cars may be taken as a reasonable number to provide for in your generating and distributing arrangements. In fixing upon 600 cars as a basis, it might be well that I should emphasize the fact that such an increase in the number of cars is not unusual, and that the above contemplated service is not excessive. In the city of Boston, U. S. A., which is of somewhat less population and of not greater area than the city of Glasgow, double this number of cars is being operated at a profit. It would be a short-sighted policy to install a system of generation and distribution which did not provide for such a growth as has been found usual, for, when the traffic has grown beyond the capacity of the plant originally installed, it is commonly found that provisions for an increased supply of water cannot be made except by an expenditure greatly beyond that which would have been originally required had the first arrangements been adequate.

2. Capacity of Generating Plant.—The consumption of power per car mile varies in different cities with the conditions of the permanent way, frequency of stops, gradients, etc. In your city the track construction adopted is admirably suited for electric traction, since the rails are of the best possible cross section, and of ample weight. The policy of charging low fares which you have adopted increases the number of passengers carried per car mile, as well as the number of stops, the result being that the amount of power which would be consumed in Glasgow is greater than that which is consumed in many other cities.

From actual measurements taken on your present electric traction works, I find your average consumption of power at the car is 7.2 kw., or 9.65 h.p. I have gone over the other lines in the city, and, having considered your traffic arrangements, have concluded that the above figure is a fair one to take for the whole system in general.

Taking, therefore, 600 cars as the number to be reckoned upon, the amount of power to be delivered to the car for average working conditions is, approximately, 5800 h.p. In traction systems the ratio of the average to the maximum load varies greatly at different hours of the day, on account of the stops for passengers and the number of passengers carried, also on different days according to the weather and other conditions. I have before me the load curve of a number of cities, and from these, as well as from your own experience, conclude that 60 per cent should be added to the average working load to provide for the maximum load that would occur under normal working conditions in Glasgow. This means that the capacity of your machinery must be such as to deliver 9250 h.p. to the cars, or, allowing for loss in transmission and distribution, approximately, 11,500 electrical h.p. must be generated as a maximum working load at the power station. Taking 85 per cent as the ratio of electrical h.p. at the bus bars to the indicated h.p. of the engine, the engine capacity for the maximum working load would amount to, approximately, 13,500 h.p. Allowing a safe margin for spare plant, an aggregate of 17,000 indicated h.p. will be required in the generating station.

3. Conditions of Electrical Distribution.—Having determined the amount of power required for working the tramway system, it remains to be decided, having regard to the distribution of cars and frequency of service, whether the supply of energy to the cars can be more efficiently controlled and economically supplied from one central point or from several points. I have come to the conclusion that, in order to meet the conditions obtaining in Glasgow, you would require several centers of distribution, for the following reasons: 1. The distances to which energy has to be conveyed are so great and varied as to preclude an economical supply of 500 volts. 2. The maintenance of your own property in gas and water mains, and the conditions to be complied with in regard to difference of potential on the rails specified by the Board of Trade, would entail in the case of a single center of distribution an elaborate and complicated return system, involving great outlay in cables and machinery, which would necessarily require subdivision into several comparatively small units in order to meet the varied conditions and the distances to which the cables would need to be carried.

The importance of this point—that is, as to the working of the earth circuits under safe conditions—will be apparent when it is considered that in many American cities incalculable damage has been done to gas and water pipes owing to electrolysis, which is brought about by the current straying from the rails. The amount of current that would be returned through your rails in Glasgow to a central point would be sufficient to eat away 50 tons of iron per annum from the pipes, which is a sufficient demonstration that the earth return is a point of primary consideration, if not the primary factor, in determining the nature of your distributing system. This becomes more evident when we consider that the maximum voltage drop allowed by the Board of Trade is 7 volts, and that in some of the central streets in Glasgow, with the increased traffic contemplated, the drop would amount to 15 volts per mile, or double that which is allowed by the Board of Trade. Practice has demonstrated that, under such conditions as those existing in Glasgow, a maximum voltage drop of not more than one-half of that permitted by the Board of Trade, namely, 3½ volts, is all that should be entertained. In other words, having reference to the safe conditions to be maintained in the track and return, in many cases in Glasgow the current should not be taken for more than half a mile from any point of distribution. Being satisfied that more than one center of distribution is an economical necessity, I find, upon further investigation into the distribution of cars throughout the system, that your present requirements can be fulfilled from five centers of distribution.

4. High-Tension Generating Station, with Sub-Stations, vs. Several 500-Volt Generating Stations.—Having determined the probable increase in traffic, the amount of power necessary to meet the demand, and that at least five centers of distribution are necessary, it remains to decide whether the energy can be the more economically supplied from a single station generating polyphase currents at high voltage, to be transformed into continuous currents at 500 volts in a number of sub-stations, or from the same number of generating stations, suitably located, and generating continuous currents at 500 volts. I have no hesitation in advising that, under the circumstances, the first, viz., the three-phase high-tension generating station, with sub-stations, is the more advantageous from every point of view.

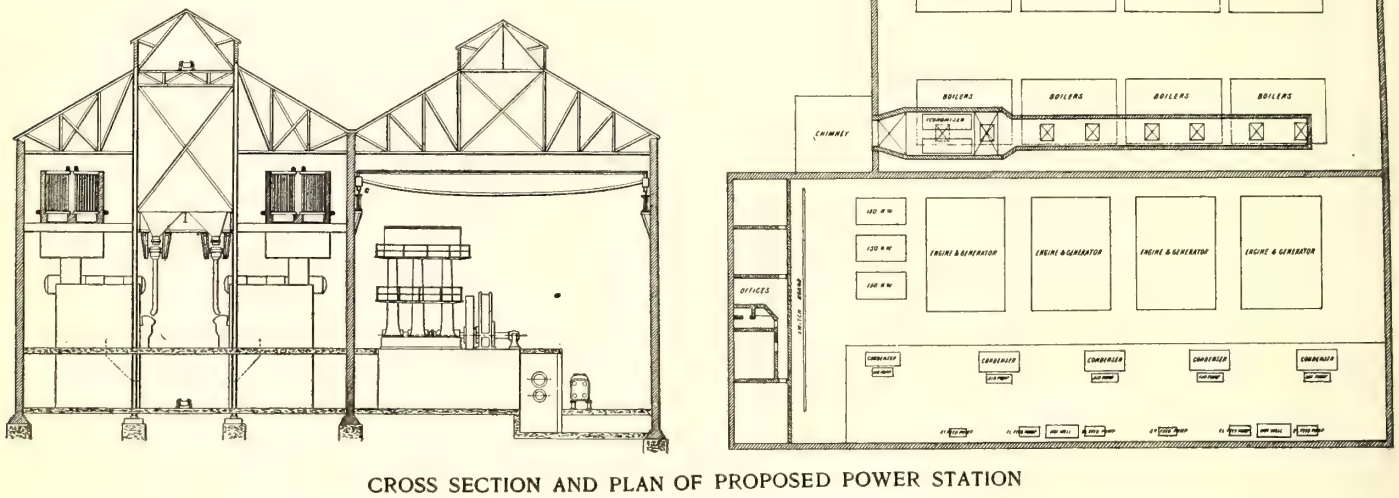
The following is a summary of the advantages of the three-phase system over the other:

(*a*) Less capital expenditure in buildings, generating plant, and in real estate investments.

On the one hand, you have to provide a site for a generating station, in the choice of which there is a considerable latitude, inasmuch as there are several sites available at such a distance from the center of Glasgow that the power can be economically transmitted at moderate cost in transmitting mains, and where you will be able to obtain the advantages of good coal delivery by more than one railway system, and also to provide for extensions. Another consideration of importance is that the sites now used as car sheds and stables are suitably located for sub-stations. No alterations would be required in the existing buildings, and the transforming apparatus would only occupy a small portion of that at present available.

On the other hand, the separate generating stations scheme would involve the purchase of four or five sites, the choice of which would be limited, if fixed with due regard to the proper working of the tramway system and suitable railway sidings for coal supply.

(*b*) The three-phase system has the advantage of less working cost and repairs. On the one hand, there is a skilled staff at the generating station, together with the unskilled labor at the several sub-stations. On the other hand, there is a skilled staff at each of the generating stations, which are equal in number to the sub-stations. It has been conclusively shown at Niagara, Dublin, Middlesboro, and other places, which have now been working a sufficient length of time so that reliable conclusions can be drawn, that rotary converters require less attention than ordinary 500-volt railway generators, and that no skilled labor is required.



There will also be a saving in supplies and repairs, owing to the use of a few large steam generating units instead of numerous smaller ones. The concentration in load also effects a saving in fuel and water. Also better facilities as to coal-handling arrangements can be afforded in a single large station than in several smaller ones. I have made a careful comparison between the two

systems, both as regards fixed charges and working costs, and append the statement to this report.

(*c*) The three-phase system has greater flexibility, and is better adapted to the requirements of future extensions. Should your lines extend further in any direction into the country, sub-stations can be installed at any convenient point or points. These sub-stations do not require special buildings; and to show the small space occupied, I may say that the 2500-h.p. stations of the Central London Railway are contained in two vertical cylinders, each 22 ft. in diameter and 100 ft. below the surface of the ground.

(*d*) In considering the transition from horse to electric traction the question of time is of great importance. The single generating station which I have recommended can be installed and put in working order more quickly than several stations. The loss through delay can be estimated upon the basis of your present working. The cost for horse traction is 3½d. per mile, on a mileage of 9,000,000 per annum; taking the working cost for electric traction on the same basis as to maintenance, etc., the saving, assuming no increase in traffic, amounts to £112,000 per annum.

In addition to the above, in installing a multiphase station you would be following the very latest and most approved practice, and you would have a type of plant that would be less likely to be superseded than a 500-volt type of apparatus, and which would have to be installed in several minor steam generating stations. This is clearly demonstrated by the experience gained in New York, Chicago and Brooklyn, where under the original arrangements the area was served by several small stations. It has been found that these small stations can be worked with greater economy by multiphase currents transmitted from a single generating station. I have before me the works cost of some of these installations, and there can be no doubt as to the economy gained.

CROSS SECTION AND PLAN OF PROPOSED POWER STATION

5. Recommendations as to the Nature and Arrangement of Plant in Generating Station.—In the event of my recommendations as to a single generating station being adopted, the following further recommendations as to the arrangement of the plant may be of use: For your traction purposes there would be consumed in Glasgow, approximately, 26,000,000 of Board of Trade units per year, or, approximately, four times as much as that generated by the largest lighting company in London. Owing to the small ratio between the average and maximum load—that is, to the load factor common to traction systems—this amount of electricity would be generated in a plant of nominal capacity of not more than one-third at which it could be generated in a lighting station, owing to the machinery working at its full capacity for many hours per day. In Glasgow you would be working the cars, approximately, sixteen hours per day, at full service, and four or five hours per day additional at one-third service. This distribution of load for so many hours per day would be very satisfactory, in that your generating station could be designed with but few units working at the best economy during all hours in the day. I find that four generating sets would give the best result—three of these to be worked during normal conditions of load, and the fourth unit to provide for abnormal conditions and emergencies.

With regard to the engines, I would recommend the use of three-crank tandem compound engines, provided with massive fly-wheels so as to give a uniform turning moment, and to provide the maximum effort for fluctuations of load. In order to obtain the best results these engines should not work beyond 75 r.p.m., and should be specially constructed, having in view the nature of the load and the conditions peculiar to an electric traction system.

The engines should be direct connected to tri-phase generators of the fly-wheel type, with rotating magnets and stationary armatures. Machines of this type have been constructed, with entirely satisfactory results, for as high a working pressure as 13,000 volts. Having reference, however, to the comparatively short distance of transmission, and the small investment in copper required, 6500 volts is a satisfactory working pressure, all conditions considered, and the calculations as to the cost of the three-phase machinery and transformers are made up on this supposition.

The station should be provided with a coal conveyor, so that the coal would be automatically conveyed from the railway trucks, or other means of transport, and distributed to different boilers, or stored in bunkers.

The station should be designed with electrically-driven auxiliaries throughout, thereby securing the greatest possible economy. The switching arrangements in the generating station would be comparatively simple, owing to the small number of generating units, and to the feeders being comparatively few in number, depending on the number of the sub-stations.

These suggestions are embodied in a plan and elevation annexed hereto.

The method of distributing the energy from a single station need not occupy much space in this report. The method you have already adopted in Glasgow, namely, of drawing your cables into ducts with manholes approximately 100 yds. apart, represents the best practice in electric traction. You will find that at a density of from 400 to 600 amps. per square inch, according to the distance, high-tension cables can be run through the same set of ducts, but where they enter the same manhole, the manhole should be of ample size, so that the high-tension cables could be carried on one side, and clear the low-tension cables.

6. Comparison of Lighting and Tramway Plants.—In reporting upon the generation of power for the tramway department, it is scarcely possible to avoid reference to the question of joint supply of electricity for the two purposes of traction and lighting. I find that on a large scale the two systems can be kept separate with advantage, owing to a difference in the nature of the plant and in the supply of power. The following are points which militate against a joint supply from lighting stations:

(*a*) On many days in the year the maximum load in lighting, and that in traction, occur at the same time, so that the same maximum total capacity in plant has to be provided, whether or not the supply is from a common station.

(*b*) Owing to the difference in the nature of the loads, the capital cost for a given watt-hour production is three or four times as great for lighting as it is for traction. In other words, the traction plant is worked at its greatest capacity three or four times as many hours in the year as the lighting plant; consequently it can be of a more substantial type with advantage.

(*c*) The machinery of a different type is commonly used for lighting, and the switching appliances are absolutely different. In the Glasgow lighting stations numerous small high-speed engines are in use; such engines are unsuited for the generation of current for your electric traction purposes. I have yet to find the engineer of extended experience in dealing with traction matters who

would propose the use of high-speed engines for such loads as you have to consider in Glasgow for electric traction.

(*d*) The electrical arrangements for electric lighting are necessarily much more complicated and elaborate than is the case for electric traction. Electric lighting has to be carried on with reference to the delicacy of the human retina; in other words, the voltage at the point of consumption has to be regulated to a nicety. In electric traction the same conditions do not obtain, since uniform acceleration and speed of the car can be obtained to the satisfaction of the passenger within a much greater range of voltage.

(*e*) From a business point of view the different conditions in electric supply are sufficiently shown by the difference in cost of energy between electric traction and electric lighting. The cost of energy for electric traction, owing to its better load factor, would not be more than 25 per cent of that for lighting. The present cost of electric lighting in Glasgow is 1.26d. per Board of Trade unit, which compares favorably with that of lighting for other cities. This figure is 4.8 times as high as would be expected in the traction service outlined. When you consider that in Edinburgh, according to published accounts, current is generated cheaper than in any other city in the United Kingdom, and when even the cost is 2.95 times that which I predict for your traction system, the difference in the nature of the load is apparent.

(*f*) It has been suggested that economy in staff will be gained in a joint station. This does not apply provided the tramway business is attended to as a business by itself. In the station which I have outlined this staff will, as I have said, be regularly employed during sixteen hours of the day at practically full load, and for five more hours at one-third load, so that the staff would be fully occupied during the hours of working. Owing to the difference in the nature of load, a different class of attendants would be required for the two classes of work.

7. Combined Stations Elsewhere.—A combined station for lighting and traction was the subject of consideration by the Bristol Tramways and Carriage Company, Limited, and by the Corporation of Sheffield. I was asked to report on the former installation, and found that there would be direct disadvantages in such a joint supply. This report subsequently received the indorsement of Lord Kelvin and the late Dr. John Hopkinson. The general absence of such combined stations sufficiently indicates that they are not in demand, as does also the fact that plant of a type now commonly used for lighting, which was originally installed for traction purposes, has been superseded by slow-speed machinery. There are two prominent examples of such plant which have been from time to time discussed, viz., the one at Toledo, Ohio, U. S. A., and the other at Hamburg. The former makes use of the slow-speed engines of a type suitable for electric traction. To the main shaft of these engines are coupled direct connected railway generators. The fly-wheels of these machines are connected by a rope-drive to countershafts, from which are driven several different types of machines, principally alternators and arc-lighting machines. The station is exceptional in character, wasteful in floor space, and employs a method of driving lighting machines which has been generally superseded in England, and could not be followed out except by mechanical arrangements which are necessarily wasteful and objectionable. The station originally worked in Hamburg has been the subject of frequent comment. This station did supply current for both lighting and traction. The plant, however, was of a type specially suitable for electric traction, and liberal use was made of storage batteries. This station has now been replaced by two stations, one supplying the energy for the electric tramways, and the other the energy for the electric lighting. It will therefore be seen that the installations above referred to cannot be considered as suitable examples to be followed by Glasgow. The established practice the world over for such large installations as you are considering is to separate the traction generating station from the lighting station.

8. Conclusion.—The conclusion arrived at in this report may be summarized as follows: Having regard to the nature of your tramway system as a whole, a single generating station, with high-tension multiphase transmission to sub-stations located in some of your existing car sheds and stables, will be found the most economical to work, involving less capital outlay, taking less time to install, lending itself to compliance with the Board of Trade requirements and to the safety of your property in gas and water mains, and being of a type least likely to be superseded when further demands are made, either as an increase in the area to be served or increase of traffic over the existing system. In following my recommendations your tramway system will be equipped with an installation of the highest class, and will not be handicapped by an attempt to make use of plant or arrangements that are either obsolete or unsuited for the economical working of your system of electric tramways.

HORACE FIELD PARSHALL.

COMPARISON OF THE COST OF CONSTRUCTION, INCLUDING BUILDINGS AND PLANT, BETWEEN A THREE-PHASE GENERATING STATION, WITH CONVERTING SUB-STATIONS, AND A SYSTEM OF SEVERAL GENERATING STATIONS.

(*a*) Cost of construction of a three-phase generating station containing four 2500 kw. units, including buildings and plant, together with plant for sub-stations located in existing car barns and stables, and including high-tension cables.

Generating station building, including excavation, foundations, steel work and brick work, foundations for engines, chimney stacks, including excavation, foundation, steel construction work, and brick lining..	£45,000	
Generating station equipment, including steam units, boilers, coal conveyors, steam mains, condensers, pumps and electrical plant, including delivery and erection.....	180,000	
Sub-stations—Cost of equipment complete of five rotary converters sub-stations, including supply, delivery and erection of rotary converters, transformers, switchboards and auxiliaries	70,000	
Three-core high-tension cables for transmission, at 6500 volts.....	21,000	
Total		£316,000

(*b*) Cost of construction for five generating stations of approximately 2000 kw. capacity, each consisting of four 500-kw. railway units.

Buildings, including excavation, foundations, steel work, brick work, foundations for engines, chimney stacks, including excavations, foundations, steel construction work, and brick lining—at £30,000 each.....	£150,000	
Generating station equipment, including steam units, boilers and conveyors, steam mains, condensers, pumps, electrical plant and auxiliaries—at £48,000 per station....	240,000	
Total		£390,000

Note.—This comparison is exclusive of the cost of ground and railway connections, which, if included, would bring out a result much more favorable to the single generating station.

COMPARATIVE STATEMENT OF COST, IN PENCE, PER KW.-HOUR, DELIVERED TO CARS ON THE BASIS OF 600 CARS RUNNING FOR SIXTEEN HOURS PER DAY, WITH 200 OF THESE RUNNING BETWEEN FOUR AND FIVE HOURS ADDITIONAL PER DAY, TAKING AN AVERAGE OF 7.2 KW. PER CAR.

(*a*) A three-phase generating station containing four 2500 kw. units, with transmission at 6500 volts, and five sub-stations containing 500-kw. and 800-kw. units, and located in present car depots.

Power Expenses.	Generating Station. D.	Sub-Station. D.	Generating and Sub-Stations. D.
Coal delivery and handling.....	0.1240	—	0.1240
Water, at 4d. per 1000 gals.....	0.0082	—	0.0082
Oil, waste and supplies.....	0.0088	0.0053	0.0141
Labor	0.0500	0.0360	0.0860
Total power expenses.....	0.1910	0.0413	0.2323
Maintenance	0.0257	0.0028	0.0285
Fixed Charges.			
Depreciation, interest, insurance, rates and taxes.....	02081	0.0616	0.2697
Totals	0.4248	0.1057	0.5305

To the above figures must be added the cost of maintenance, depreciation, and interest upon the high-tension cables for connecting the generating station to the sub-stations, amounting to 0.019. This makes the total cost of the three-phase scheme 0.5495.

(*b*) Five generating stations containing 500-volt railway generating plant.

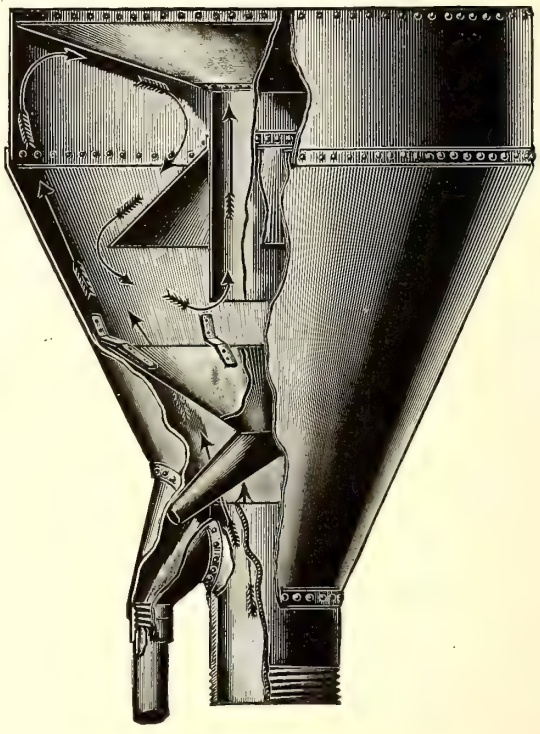
Power Expenses.	D.
Coal, delivery and handling.....	0.1550
Water, at 4d. per 1000 gals.....	0.0103
Oil, waste and supplies.....	0.0110
Labor	0.2000
Total power expenses.....	0.3763

Maintenance	0.0350
Fixed Charges.	
Depreciation, interest, insurance, rates and taxes	0.3254
Total	0.7367

Note.—The above figures do not include interest on the cost of sites and railway connections.

The difference as between .5495d. for the single multiphase station and .7367d. for the five 500-volt stations, based on 600 cars, amounts to £20,280 per annum as the saving in working costs in favor of the single multiphase station.

REPORT OF SUB-COMMITTEE



The sub-committee of the tramways committee on the generating and distributing of electric power for tramway traction drew up the following report on Mr. Parshall's recommendation, and the tramways committee, at a meeting held the same afternoon, unanimously approved of it.

The sub-committee's report was as follows: From our study of the report, and of the subject generally, we believe the advice given is sound from the economic as well as from the engineering point of view, and it clearly points to the tramways committee generating, distributing, and controlling their own power, and we think that, in view of the information contained in the report, it is scarcely necessary for us to report at any great length. We are quite convinced that the power will be produced cheaper by having one generating station for the tramways at, say 6500 volts, with district sub-stations in our present tramway depots, as suggested, each of which would form a distributing center, than by having separate installations of plant at several power stations generating current at 500 volts. We think it is also established that, for the tramway system of the near future, which will extend, at numerous points, to a considerable distance beyond the city limits, a high-tension station with sub-stations, as suggested, will be most efficient, and will best fulfill the requirements of the Board of Trade, and avoid electrolysis of the water and gas pipes. We have also before us the important fact that the maximum loads for lighting and traction occur at the same time. From the information now before us, it is evident that for the most economical as well as best mechanical results, entirely separate and different machinery is required for traction and for lighting purposes respectively. It also seems obvious that the undertaking which each of the departments in question has before it at present is sufficiently large of itself to admit of the adoption of the most economical generating units and the production of current at the lowest possible cost. That the electricity committee could supply current for the tramways need not be questioned, but so far as we know they do not claim that they will be able to supply it either better or cheaper than the tramways committee could produce for themselves. They could only produce it as cheaply as the tramways committee by putting down special traction machinery for the purpose, and in that case, in order to arrive at the exact cost, the power for traction would require to be produced and accounted for as a separate undertaking, just as if the tramways committee were producing it for themselves. It is clear that the supplying of power for the tramways by the electricity committee could be of no possible benefit to them unless they were to do so at a profit, which is quite inadmissible. After the fullest consideration of the whole circumstances of the case, our conclusion is that to have the power stations for lighting and traction combined would be of no benefit to either committee, but that, on the other hand, any such arrangement would be a great disadvantage to the tramways department. As pointed out in Mr. Parshall's report, with a continuous traction load for over twenty hours out of the twenty-four, as against only a few hours' continuous lighting load, the tramways committee can take about four times the work out of their plant that can be taken out of the same amount of plant for lighting. In addition to what has already been suggested, this gives the tramways committee another distinct economic advantage in putting down their own plant and producing and distributing their own current on the lines indicated. A still greater advantage is clearly obvious in the matter of administration. The responsibility for the operating of the tramway system should undoubtedly carry with it the control of the power, which is the mainspring of the whole concern. Whoever controls the power controls the tramways. The tramways department, being a commercial undertaking, has always been self-contained, and, in our opinion, should remain so. The tramways committee have supplied the horse power. They have also supplied the electric power for the sectional demonstration. Now they are in a position to begin generating their electric current for the whole system on the best known principle, and with the most up-to-date machinery for this special purpose. Keeping in view the magnitude of the operations confronting both committees, we can see no benefit whatever to be gained, but quite the reverse, by any combined arrangement, which would mean two separate committees being engaged in carrying out the powers of the Tramway acts, one committee supplying the power and another working the tramways. Any such dual control should, in our opinion, be avoided. We have, therefore, pleasure in recommending that the tramways committee, who are responsible to the corporation for the efficient working of the corporation tramways, be still entrusted with the supplying and distributing of their own power for electric traction, and that it be remitted to that committee to proceed to convert the tramways and arrange for the supply and distribution of power on the general lines indicated by Mr. Parshall.

The report was later adopted by the Glasgow Corporation by a vote of 56 to 4.

Exhaust Heads for Power Plants

Marlin & Co. of Pittsburgh are making some of the largest exhaust heads ever installed in this country. All of the heads manufactured by this company are of the best galvanized steel, thoroughly riveted and soldered, and in their operation are as follows: The exhaust steam in rising passes by a conical shaped drip pan,

EXHAUST HEAD

then passes near the outside of the head, and finally into the atmosphere through a central outlet. In its passage a considerable part of it is condensed, the water from condensation being all led off through a drip. The head is built on a piece of welded steam pipe, which extends inside far enough to form a channel that connects with the drip. The diaphragms for presenting a large condensation surface are held in position by heavy wrought-iron braces. The drip is so arranged that it cannot become clogged or frozen. It separates the water and oil from the steam, and exhausts the dry steam, thereby avoiding damage to neighboring walls and roofs. It is claimed that these exhaust heads cause no back pressure on the engine, and are noiseless in their operation.

Interesting Electrical Publication

The March issue of the Electrical Engineer and Telephone Magazine, a paper published in Chicago in the interests of electrical and telephone engineering, contains a number of articles of special interest. Among these are "The Drake Selector System," by Thomas C. Drake; "The Algebra of Electricity," "The Inspector and the Trouble Man," by the Inspector; "A Trip to the Pole Country," and a "Digest of the Telephone and Kindred Patents," by Edward E. Clement.

The Harrisburg Standard Self Oiling Engine

The Harrisburg Foundry & Machine Works, of Harrisburg, Pa., after long experience in steam engineering, have designed a system of engines now known as the "Standard" or "Harrisburg Standard," which they believe will meet all possible requirements for high, medium and slow speed engines up to units of 3000 h.p. The name of the Harrisburg Foundry & Machine Works has long been a familiar one to steam users, through their engines known as the "Ide" and "Ideal." More recently, the "Harrisburg Standard" has been evolved from the experience had with the other engines, embracing the good points of the others.

The "Harrisburg Standard System of Engines" include simple engines, and tandem compounds with single valves; and simple tandem and cross compound engines with four valves, medium and slow speed, the latter of the "Corliss" rocker type. The accompanying engravings illustrate in turn these new machines, commencing with the Harrisburg Standard simple valve engine. A peculiar feature of the new engine is that they are all constructed with side cranks, requiring only two main bearings, whether designed for direct coupled or belted service, and thus many of the disturbing elements, such as excessive friction from bad alignment, that attend the operation of three or four bearing engines, are removed, the friction in these engines being in many cases as low as 2 per cent.

The simple engine is made up to 36 ins. diameter and stroke, and, as will be noted in the accompanying illustration, Fig. 1, is compact and graceful in design and its high efficiency is due to a combination of features, none of which are experimental, however. These salient features include, in addition to the above, an automatic oiling device, by which the crank disc, connecting rod and cross head are enclosed, the latter provided with a hinged hood which may be turned back, and a plate on the side, which may be easily removed for inspection, and adjustment of reciprocating parts, as shown in Fig. 2. This arrangement of hood makes removal unnecessary as all adhering oil drains back into the engine frame. By the revolution of the disc in the oil, the rim of which touches its surface, it is splashed over the wearing parts, including the cross-head, and by means of a lateral trough across the inside of the cover a large portion of the oil is led through a pipe and directed in a stream upon the main bearing adjoining the crank disc. The lubrication of the crank pin is accomplished in a very ingenious manner, by means of an eccentric annular chamber, recessed in the face of the disc around the main shaft next to the main bearing, from which a diagonal hole is drilled through the disc, coming out about the middle of the surface of the crank pin, so that by centrifugal force instead of by the too uncertain force of gravity, a constant volume of oil is provided for its lubrication, completing the circulation from reservoir to crosshead, main bearing, crank pin, and finally draining to reservoir again.

The patented governing mechanism is also a special feature of these engines. It is of the fly-wheel, technically termed, centrally balanced, centrifugal-inertia type, and is claimed to be sensitive to regulate to 0.5 per cent in load variations from zero to 125 per cent. Roller bearings are provided in the governor bearings and the principal mechanism consists of two balance levers, which are connected to an eccentric sleeve which surrounds the shaft, and which is pivoted at one side, so controlling the throw of the eccentric rod to a nicety.

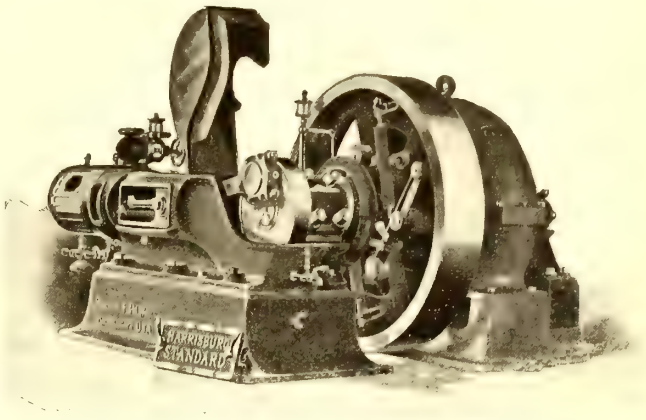


FIG. 2.—VIEW OF ENGINE, SHOWING OILING DEVICE

The pillow blocks for the crank shaft have the cover fitted in a diagonal position, and the shell is provided with an oil chamber with recesses for the oiling chains. The engine frame is extended with stuffing box exposed in such positions as to provide for constant use and easy access, and prevents the water of condensation from getting into the oil supply, should a leak occur. The oil is prevented by a guard from getting on the piston rod. In the process of manufacture, the pistons, piston-valves, pins and other parts are all ground to an accurate fit, and micrometer records made of each piece, so that any part of an engine can be duplicated

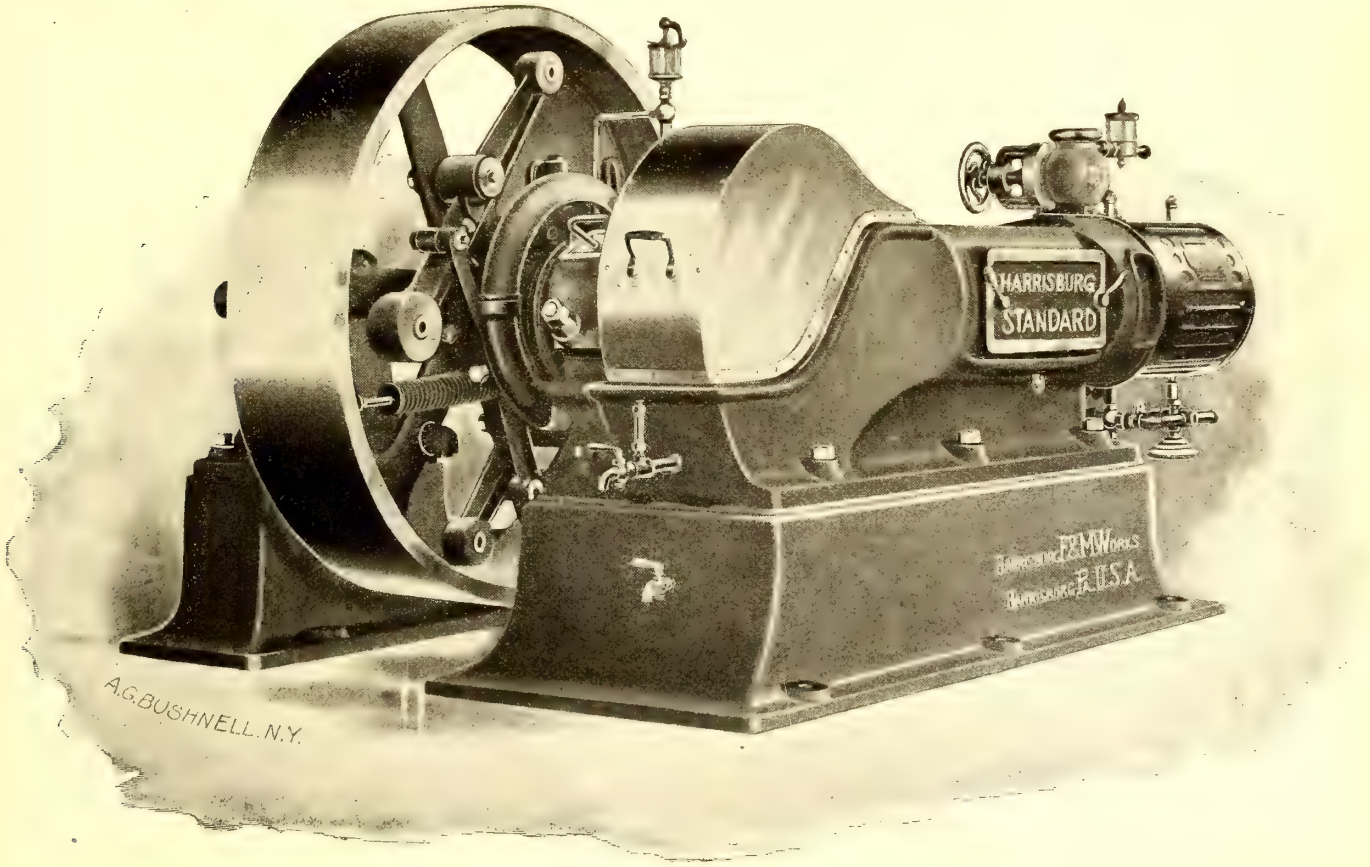

FIG. 1.—VIEW OF SIMPLE STANDARD ENGINE

at any time after it leaves the works. The crank disc, including the pin, is cast in one solid piece of steel, the mould being placed in a horizontal position, with the pin down, producing a dense metal in the pin. This is afterward turned and properly fitted, when the disc is shrunk on the shaft and keyed in position.

Every engine is thoroughly tested before it is shipped, and for this purpose metal bed plates on heavy masonry are provided with suitable channels for clamping them in place. When in position for testing, the engine bed is supported on metallic points, and the machine is first run for adjusting the governing and valve mechanism. Next, the fly-wheel is accurately corrected to a running balance, and finally each engine is so perfected that it is run upon the metallic points without fastening. Very accurate and elaborate tests are made to perfect the governing mechanism of each engine, and when the machines leave the shop, a guarantee can be given as to their exact performance.

It is a principle in these works never to turn out a second grade article, and the general workmanship, material and construction of the new engines are all up to the highest standard.

Although the "Harrisburg Standard Engine" was designed but a year ago, there are already in operation nearly a hundred of these machines, with orders for thirty more in the shop.

The Harrisburg Foundry & Machine Works also manufacture road-rollers to a considerable extent, and also tubular boilers, and in order to meet the growing demands of their trade, are erecting extensive shops at West Harrisburg, for which the walls and stack are nearly up. The ground dimensions of the main building are 300 ft. x 140 ft., and it is intended that all departments, including the foundry, shall be under one roof. The designs show that this is to be an up-to-date establishment in every particular, and the equipment will embrace the latest improved machinery, suited to this class of work.

The affairs of the company are under the management of W. R. Fleming, who was induced to give up his engineering business in New York for this purpose and who has had much to do with the designing of the "Standard" engine. Mr. Fleming took charge of the company's affairs Jan. 1, 1898, since which time the output of the establishment has shown an increase of 45 per cent over the previous year.

Handsome Interurban Cars

The accompanying photographs show both interior and exterior views of interurban cars recently manufactured by the St. Louis Car Company for the St. Louis & Belleville Electric Railway Company, which operates between St. Louis and Belleville, Ill. The cars are 46 ft. over all, with steam coach roof and closed vestibules at each end, and are mounted on the St. Louis Car Company's No. 18, high-speed, double-motor trucks. The cars are also equipped with Christensen air brakes, and four G. E. 57 motors to each car, and weigh complete about 48,000 lbs. each. The cars have a partition at one end, measuring about 9 ft., with a seating capacity of twelve passengers, which will be reserved as a smoking compartment. The seats are St. Louis Car Company's patent, leather covered, "walk-over" type, twelve on each side of aisle, with a seating capacity of forty-eight passengers to the car.

The cars have nine double sash on each side, with six closed panels from outside, as shown in the illustration. The panels on the inside of the car are fitted with large French beveled mirrors, and all sash is fitted with French plate glass. The vestibules have five drop sash, and are provided with a folding door on one side.

The interior finish of the cars is of solid mahogany, finished in natural color, and all mouldings, head pieces, etc., are handsomely hand carved, and all inside trimmings, which are solid bronze,

FIG. 1.—INTERIOR VIEW OF CAR—BELLEVILLE, ILL.

stand out in bold relief, and present an extremely tasteful appearance. The curtains are of red silk faced pantasote, mounted on spring rollers, and provided with St. Louis Car Company's wire cable fixtures. There are also twenty-four electric heaters in each car, one placed under each seat, thus insuring plenty of warmth for passengers.

The ceilings are of a very delicate blue, ornamented in gold, and the electroliers, of fancy design, are in five-light clusters, with opalescent globes in center. Cars are also furnished with electric signal bells, push buttons being placed at every seat.

The outside construction of the car, as can be seen, is of steam railroad type, with straight sides, heavy truss rods, etc. The cars are also equipped with two Wagenhals electric arc headlights, one at each end, of 5000 candle power each, which enables the motorman to see an obstruction on the track as well at night as day.

In addition to the air brakes, the cars are also equipped with St. Louis Car Company's solid bronze ratchet hand brake, and are also supplied with an air whistle, instead of a gong, as is ordinarily used on street cars. The cars are painted Aurora red and light

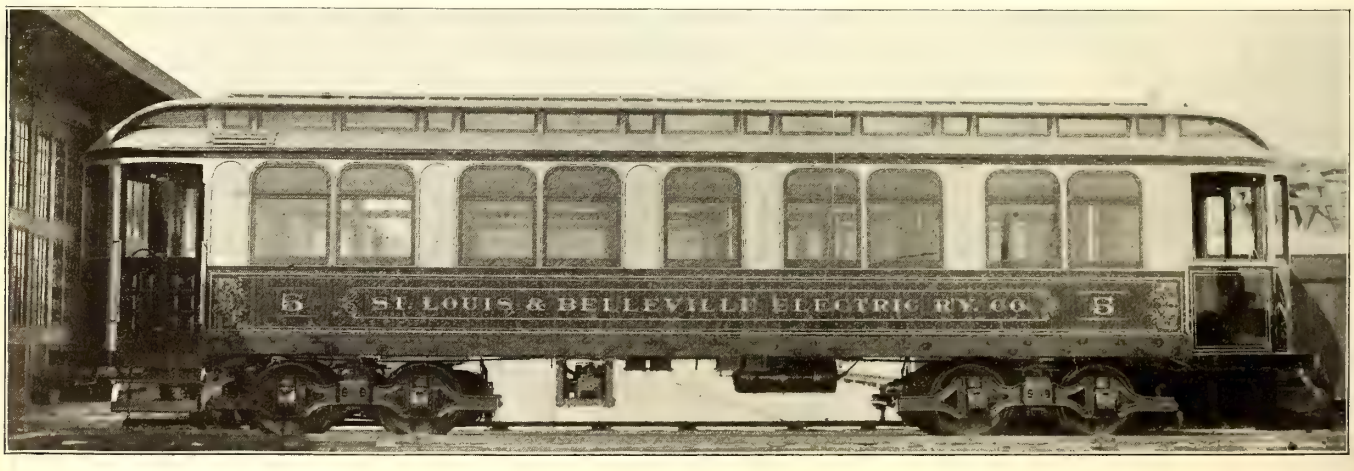

FIG. 2.—EXTERIOR VIEW OF NEW INTERURBAN CAR—BELLEVILLE, ILL.

lemon yellow, a very pretty combination, with neat lettering and ornamenting on the sides.

Fig. 3 shows an electric locomotive which was built by the St. Louis Car Company for the San Antonio Brewing Company, San Antonio, Tex., and which is equipped with automatic freight car couplers, and four G. E. 57 motors, mounted on St. Louis Car Company's No. 15 double trucks. This locomotive is capable of handling from ten to twelve car loads of freight, with the utmost ease.

The St. Louis Car Company also employs an electric motor of this type, for switching purposes at its works, and finds it not only a great convenience, but a labor saver as well.

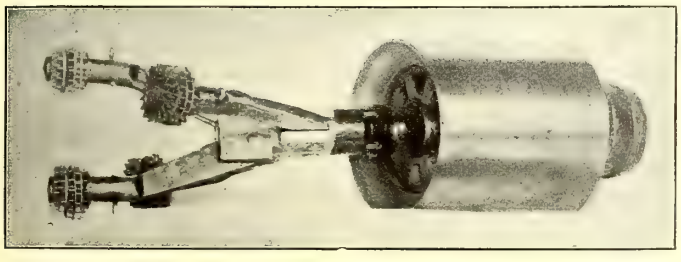

FIG. 3.—ELECTRIC FREIGHT LOCOMOTIVE—SAN ANTONIO, TEX.

Cleaning Water Tube Boilers

Almost every quality of feed water has been found to contain more or less scale-forming ingredients, and where boilers have been allowed to run a year or more without careful cleaning, scale has in many cases accumulated to the thickness of ½ in. or more. Any considerable thickness of scale not only adds very largely to the fuel bill, but it greatly impairs the efficiency of the boiler, reduces its capacity, increases cost of repairs and shortens its life.

The manufacturers of water-tube boilers and others interested in the subject have made numerous experiments with the idea in view of adding to the life of the boilers by removing this scale by mechanical means. One of the latest machines for this work consists of a specially designed turbine attached to the end of a wire-wound hose, and driven by a water pressure of from 90 lbs. to 125 lbs. This pressure causes the turbine to revolve with great force and power, throwing the four heavy cutting arms outward by centrifugal force against the scale with sufficient power to cut and pulverize it into powder, which the flow of water washes away. A series of solid cutting heads and drills is furnished with this cleaner, which is designed to penetrate solid scale, and, at the same time, to save the more delicate parts of the flexible head.

HEAD OF BOILER CLEANING DEVICE

In designing a cleaner which would enter 3-in. tubes and pass around the bends which some of them contain, it was found necessary to condense a large amount of power into a very small compass. It was thought an impulse cleaner does not contain sufficient power to remove heavy scale, and the turbine type of waterwheel was used.

It is this feature which, the manufacturers claim, gives about five times as much power to the turbine as to the impulse cleaner. It is amazing to know the quantity of scale which many of these machines have removed, at a cost of from ten to forty cents per tube. The cleaning of water tubes by this process not only removes the obnoxious and expensive scale, but polishes out the tubes, and, in fact, leaves them in better condition than when new. The cleaner is adapted to any type of boiler, horizontal or upright, with straight or bent tubes, and can be carried by the operator to the top of a boiler, around any obstruction, into the manhole of a steam drum, or wherever he can go. The machine is manufactured and sold by the Chicago Boiler Cleaner Company, Chicago, Ill.

Lubricating Greases

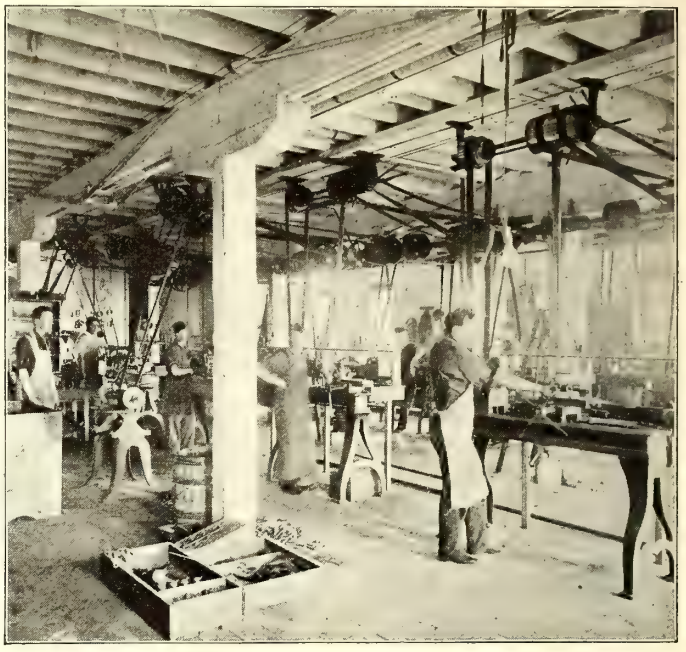
The announcement is made that Dreher journal grease has again been placed upon the market in a somewhat improved form for the use of street railway companies. This grease has been widely used by steam railroads, and is well known to most steam railroad managers. It has been used by the Pennsylvania Railroad Company with excellent results for a number of years. The grease is so compounded as to lubricate only when the car is in motion; as soon as the car stops the grease hardens or "checks," thus avoiding all drip or wasting. The grease in addition to its lubricating qualities is extremely cooling and cleansing, preserving a smooth, clean surface for the journals at all times. It is stated that one application of this compound will suffice to run a car 12,000 miles.

The manufacturers of the Dreher journal grease are also introducing a motor grease which, it is stated, will greatly prolong the life of street railway motor armatures. It is claimed 1 lb. of this grease will carry a car 500 miles, thus making it more economical than lubricating oils, and at the same time giving better results. Particular attention is paid in the manufacture of both these compounds to giving them the necessary body.

The Dreher Grease & Oil Company, of New York, which is now manufacturing these products, is receiving numerous testimonial letters stating that these lubricants are giving excellent satisfaction. One of these recently received from the foreman of the Fifth Avenue depot of the Nassau Electric Railway Company, of Brooklyn, reads as follows:

"I made a test of the grease you sent me as a sample, and can state that the test was very satisfactory in every way. I can recommend it to any one in need of an A1 grease, both for motor and journal bearings.

"The 10-lb. sample of motor grease was used on one of our Westinghouse equipments for forty-two consecutive days with an average of 125 miles a day, making a total mileage of 5,250 miles. No oil was used during this time. The 15-lb. sample of journal grease was used on the same car and ran 11,250 miles with a packing of wool waste. No oil was used at all."



The Manufacture of Electric Railway Supplies

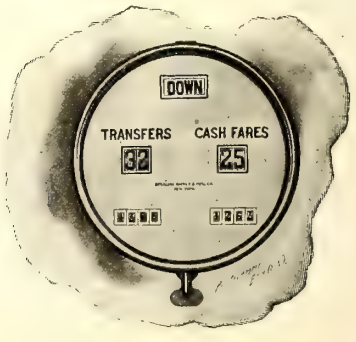
It is always interesting to know where and how particular things are made, and this is especially true of such electrical and mechanical appliances as enter into the overhead construction of city and suburban electric railways. To this end a visit was recently made to the works of the Ohio Brass Company, Mansfield, Ohio, which is one of the largest manufacturers of this class of goods in any country. It will be impossible, however, to name in detail all the various appliances made here, for the illustrated catalogue of the company gives a list of over 400 articles manufactured for the above purposes, and these include not only specialties in overhead material, but also car and motor parts.

The works are located on the outskirts of the city, near the Union depot, and at this season, while running double shift, they employ about 200 hands. The main building is a three-story brick structure 300 ft. x 75 ft., having a wing of the same material 150 ft. x 100 ft. Back of the main building is the brass foundry, a one-story structure 200 ft. x 100 ft., and a japanning building 50 ft. x 60 ft. The business was established in 1888, originally as a jobbing shop, but in 1890 began to manufacture street railway supplies, and the business has steadily increased from year to year, and during the last year turned out 120 per cent more material than the year before, and now shipments are made to all quarters of the globe. The products, however, are not confined entirely to brass, as the name of the company might imply, but embrace products in malleable iron amounting to many hundred tons per year. Much of the malleable iron material is galvanized on the premises by an electrolytic galvanizing process, giving a much more thorough finish than where galvanizing is done by the dipping process. The company also does its own nickel plating and japanning. The departments embrace a brass working shop, in which there is a fine complement of metal working tools, together with testing appliances and trucks and crates for the shifting of the material about the works. The iron working department is similarly equipped, and in both cases the shafting is driven by an electric motor of the Card type. Testing machines are employed for determining the tension strength of materials up to 10,000 lbs. capacity, and there are transformers which give a 10,000-volt current for electrical testing. A large product of the establishment consists of insulating material which the company has named "Dirigo," and which is giving excellent service. In the manufacture of this material a special department is employed in which there are a great number of hydraulic presses and other machines. The company employs a corps of competent engineers and draughtsmen for originating special designs in every department of the work, and also for such new devices as are suggested by particular customers.

The brass foundry is of ample proportions and has twelve smelting pits, together with the ordinary foundry equipment which includes twelve tumblers for smoothing up the small castings. In connection with the plating department is a large number of emery grinders and buffing machines, all of which are provided with exhaust pipes for removing the dust. The japanning department is equipped with two large baking ovens with suitable racks for drying the material, and joining it is the tinning department, in which are the usual tanks for acid baths and melting kettles. The stock and tool room is especially well designed, there being a large number of shelves, cases and racks for storing in separate receptacles the great variety of products. The shipping room is of ample proportion, and right alongside are tracks from a neighboring steam railway, so that material for shipment is loaded directly into the cars without any trucking. There is also a wood working department, in which the patterns and templates and shipping crates are manufactured, from which it will be seen the works include almost every branch of the mechanical trade. Power is supplied from a 75-h.p. engine, while there are generators for lighting and power. The boiler equipment consists of two 50-h.p. and one 100-h.p. boilers.

The offices of the company are located on the third floor of the main building and occupy rooms with glass partitions on two sides of a reception room of ample dimensions, all being finished in Georgia pine. Adjoining on one side is a sample show-room, in which samples of almost all materials manufactured are placed on shelves and in cases, making a very attractive museum.

VIEW OF MACHINE SHOP



The affairs of the company are operated under the direction of E. T. Cooke, president; B. F. Blymyer, vice-president, and C. K. King, secretary and manager of the railway department; F. P. Black, treasurer, and William Bunting, superintendent. The New York office of the concern is located in the Commercial Cable Building and is under the management of R. A. Byrnes.

VIEW OF BRASS FOUNDRY

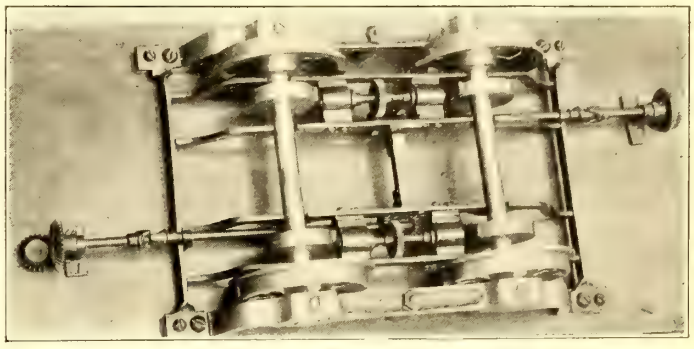
Double Registers

The practice on street railways, where one register only is used on each car, differs as to whether it is better to record transfers or not. Arguments can be cited in favor of both plans, but the fact that such a diversity of opinion exists would seem to show that the double fare register, in which a record can be kept of both cash fares and transfers, would satisfy both sides and consequently have wide application. The prevailing tendency of railways is undoubtedly toward the extension of transfer systems, especially in the case of consolidated roads, so that every new device of this kind possesses much interest. A double register can also be used for recording two rates of fares upon long interurban roads.

NEW DOUBLE REGISTER

The accompanying engraving shows a double register recently brought out by the Sterling Supply & Manufacturing Company, and which consists really of two distinct registering mechanisms inclosed in one case. The appearance of the register is very similar to that of the well-known Sterling numeral register, except that there are two sets of dials instead of one, each set being operated by a separate cord or rod. The mechanism is operated through a train of gears and not entirely by springs, and the gear connection between the trip and the totalizing wheels is positive, no cams or dogs being used. The construction is similar to the well-known Sterling standard and every working part of the register is a carefully tested steel casting and all parts are interchangeable. The interior mechanism is compact and simple and the finish of the case is durable and handsome.

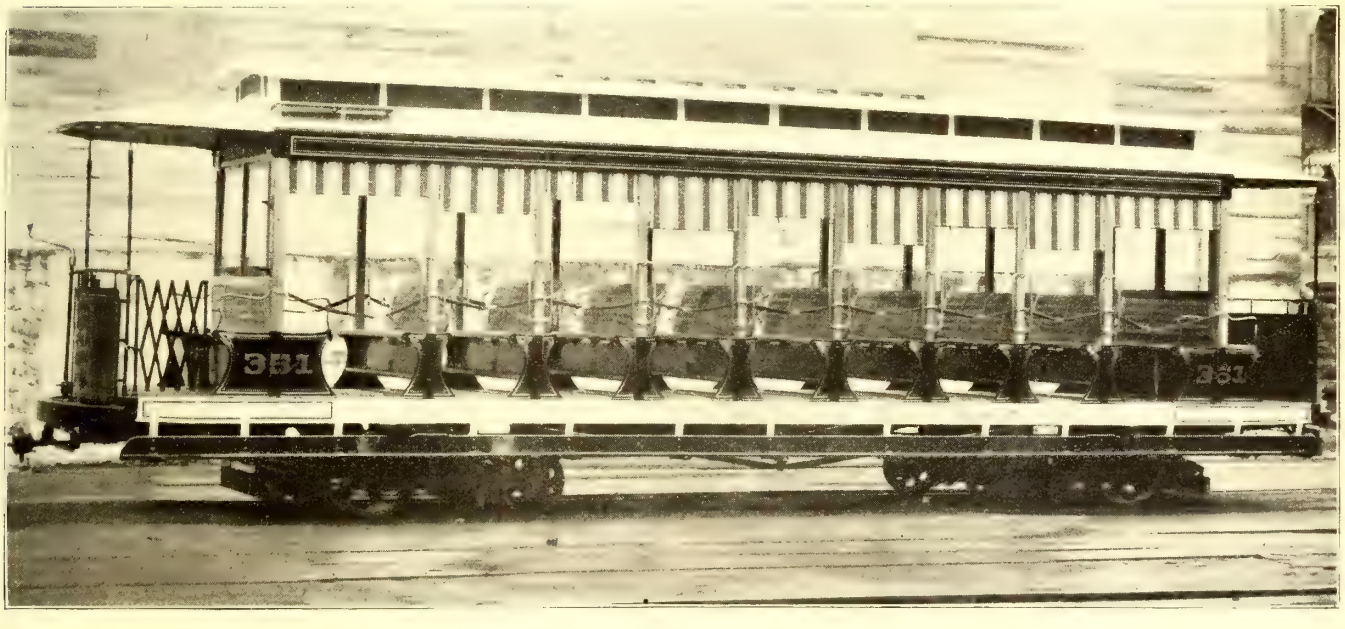
Open Cars for a French Railway



The car shown in the accompanying illustration is of considerable interest, since it seems to be the first open car of purely American type ever sent to Europe. It is from the shops of the Brill Company, and is of the standard twelve-bench type, and is mounted on Eureka maximum traction trucks. The length of the body is 34 ft. It is 43 ft. 8 ins. over the buffers. The limitations of French streets, however, come in, and a breadth of only 5 ft. 10½ ins. is permitted at the sills. This is increased to 6 ft. 5 ins. at the posts, but the extreme width at any part had to be kept down to 7 ft. 8¾ ins. For this reason, although the car has twelve benches, its seating capacity will not exceed forty-eight persons, allowing the American standard of 17 ins. each. The platforms are 4 ft. long, and are separated from the body of the car by bulkheads in the usual manner. On account of the narrowness of the bodies only two sash are placed in these bulkheads. The peculiar form of the grab handles seen on the post is also made necessary by the narrowness of the body and the limiting width over all. The openings between the seats are closed by leather-covered hook chains. The interior finish is of bird's-eye maple for the head lining and ash for the trimming over the openings.

The trucks have 30-in. and 20-in. wheels, with a 4-ft. wheel base, and are furnished with G. E. 1000 motors. The gage is 4 ft. 8½ ins. These cars without motors weigh 15,275 lbs. The weight of one of the trucks was 3000 lbs. The steps are 18 ins. from the ground, with a 15-in. riser. The openings are closed by curtains which come to the floor, the round-corner seat-end panels enabling this to be done easily.

Shipment was effected after the car was entirely completed by taking it apart in sections and packing it closely in boxes. The great length of the car is particularly noticeable, showing that the French street railway people at least are waking up to the advantages of as large a car as can be used on their streets.



Novel Design of Brake for Street Cars

The accompanying illustration shows a device of the inside brake type. It is quick acting in operation, and, as will be noted from the illustration, the shoes act on chilled drums, attached to the axles, the shoes working between the drums. The shoes are forced against the wheels by means of a shaft, which terminates in right and left screws, that force the shoe heads in opposite direction. This shaft is operated through the medium of spur gears, which, in turn, mesh into the corresponding gears on a shaft that extends under the floor of the car, and which is provided with a universal joint and terminates in a beveled gear, which meshes

NEW BRAKE

into a corresponding gear on the lower end of the brake spindle. An auxiliary shaft, provided with beveled gears, couples the two shoe shafts together, as shown, by which means the brakes of all the wheels may be operated from either end of the car. As the shoes operate on the rim of the inside drum, a very close adjustment can be maintained at all times, so that very little exertion is required on the part of the motorman to bring the shoes into action, while the threading of the shaft provides for the automatic adjustment as fast as the shoes wear. The drums are of the split type, and are keyed and fastened to the axle in the usual manner. This brake was designed by John T. Duff, of Allegheny, Pa., and he claims that it can be adjusted to any type of truck, and so arranged as not to interfere with the mounting or dismounting of the motors. The brake has been worked experimentally and seems to sustain the claims that are made for it.

OPEN CAR FOR A FRENCH RAILWAY

The plant of the Rhode Island Locomotive Works, at Providence, R. I., was formally transferred to the International Air Power Company on Mar. 14. It is reported that the price paid was about $3,600,000. It is also stated that the bond holders of the locomotive works received a mortgage of $225,000 on the property.

Lightning Arresters for Street Railway Circuits

Overhead circuits during storms become highly charged with an induced static electricity—the difference of potential existing in some instances between the line and the earth; in others, between the different sides of the circuit.

Owing to its high oscillatory character, this electricity will not discharge through a coil, but will, in preference, select some path of low inductance, even though of higher resistance. It is due to this fact that when the discharge seeks a path to earth through the coils of a dynamo, motor, or other apparatus, it punctures the electrical insulation of the machine and takes a path to earth generally through the layers of the armature to the core, or over the air space to the pole pieces. The normal current of the line following the lower resistance thus established causes a "ground," or short circuit, and a consequent burn-out. It is the function of a lightning arrester to offer the discharge a better path to the earth. Experience shows that the static discharges will go over the infinitely high ohmic resistance of an air-gap rather than through a few turns of a coil of but a few feet in length.

The Garton-Daniels Electric Company, of Keokuk, Ia., after an experience in manufacturing lightning arresters of six years, has designed an arrester that takes advantage of this peculiar action of static electricity in protecting electric plants and circuits from damage due to lightning discharges. A cross section of the Garton arrester is shown in Fig. 1.

Referring to this illustration, the course of a discharge is as follows: It enters the arrester by the binding post *A*, thence across non-inductive resistance *B*, which is in multiple with the coil *F*, through conductors imbedded in the base of the arrester, to flexible cord *C*, to guide rod *D* and armature *E*, which is normally in contact with and resting upon carbon *H*, thence across the air-gap to the lower carbon *J*, which is held in position by bracket *K*. This bracket also forms the ground connection through which the discharge reaches the earth. It will be noted that the discharge takes its path through the non-inductive resistance in multiple with the coil. The path is, however, of high ohmic resistance, and the normal current is shunted through the coil *F*, which is thereby energized, drawing the iron armature *E* upward instantly. This forms an arc between the lower end of the armature and the carbon *H*.

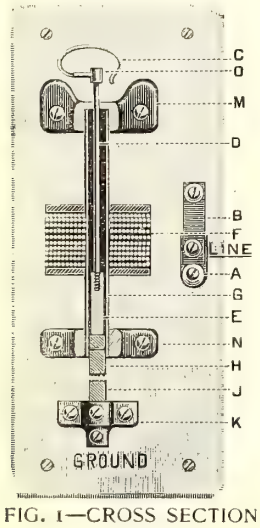


FIG. 1—CROSS SECTION OF ARRESTER

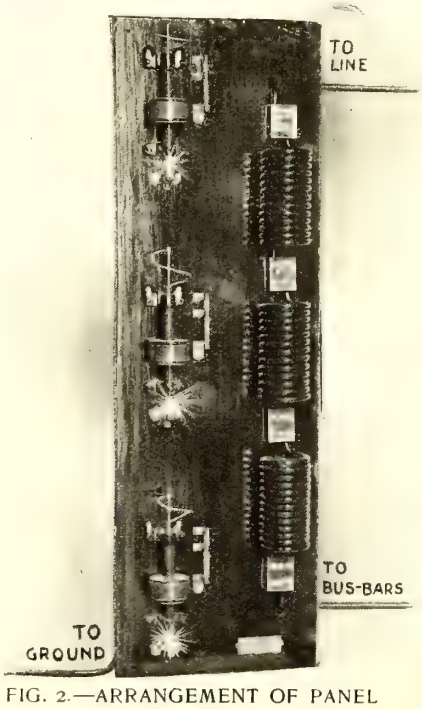

FIG. 2.—ARRANGEMENT OF PANEL FOR RAILWAY CIRCUITS

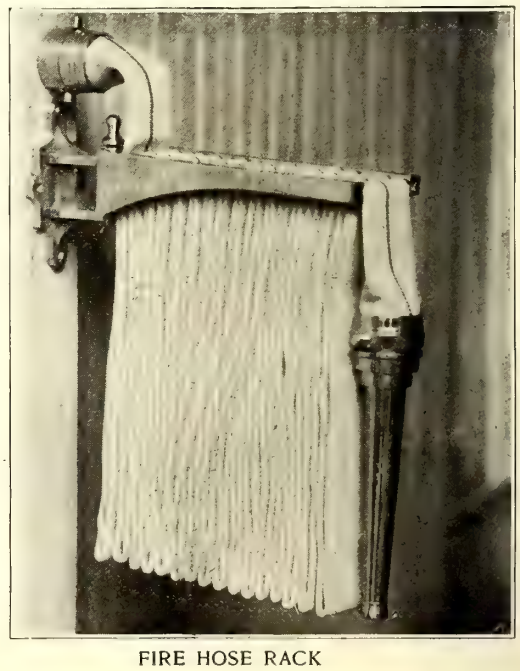
As this arc is formed inside the tube *G*, which is practically air-tight, the oxygen is consumed, the current ceases, and the coil loses its power, allowing the armature to drop of its own weight to its normal position on the upper carbon. The arrester is again ready for another discharge.

In the railway types a portion of the resistance rod is connected in series with the coil, thereby limiting the flow of current following the discharge. This is necessary, as the normal as well as the static difference of potential is between the line and the ground. This non-inductive resistance is so low that, while limiting the flow of normal current, it does not limit the flow of static electricity, as the potential of the latter is so vastly higher than the normal voltage of a railway circuit.

Arguments have been made against lightning arresters with moving parts, but practice has shown many of these fallacious. The Garton arrester comprises moving parts, but it is so simple and the parts so arranged that all the difficulties anticipated in a device of this character are entirely obviated. The most convincing proof that moving parts are not always objectionable is in the success of the Garton arrester under the most trying conditions.



Every operation of this arrester cleans the contacts and discharge points, thereby keeping the conductivity at a maximum and the resistance at a minimum. The arrester is so quick in its action that discharges in rapid succession are taken care of with the greatest ease. After a discharge the Garton arrester increases the resistance in the circuit and chokes and disrupts the current flow. This action is made so quickly that a sensitive plate is incapable of detecting any motion.

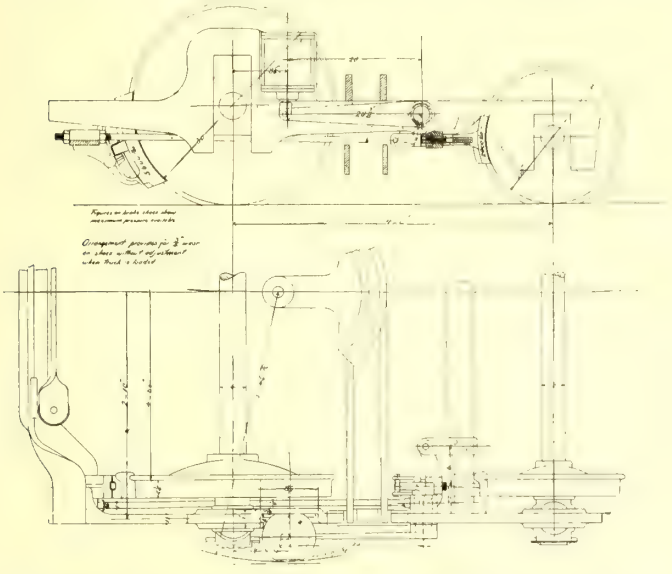
The usual arrangement of arresters for the protection of a street railway power station is shown in Fig. 2. Here, it will be noticed, the arresters are used in connection with kicking coils, which consist of a coil of wire so designed as to offer the least ohmic resistance and the highest inductive resistance. One is placed in each circuit, between the apparatus to be protected and the lightning arresters. Acting in the same way as the coils of an armature, which drive the discharge through the insulation to the core, the kicking coil drives the discharge through the lightning arrester before it reaches the machine.

It will be noted that by placing coils and arresters as shown, the discharge passes through the upper arrester; any excess discharge will be taken care of by the second and third, and the three kicking coils offer an inductive resistance that effectively protects the generator. The Garton-Daniels Electric Company is now mailing its 1899 catalogue, which contains a complete description of its line of aresters for this year.

Fire Hose Racks and Reels

The hose rack and reel illustrated herewith, and which are manufactured by H. J. M. Howard, of Washington, D. C., ought to appeal to station and car house foremen, who desire to have their fire protective apparatus ready at hand and yet out of the way when not in use.

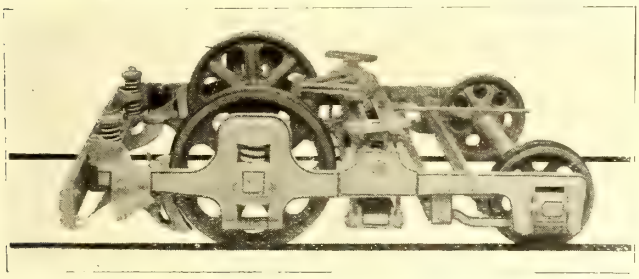
FIRE HOSE RACK



The method of hanging hose on wooden pins, illustrated, avoids all possibility of hose rusting and prevents the sharp bends so objectionable in other styles of racks. The hose being supported in this manner allows the air free circulation through the folds of the hose, keeping it dry at all times. At the same time it is quickly available, as the side arms can be swung out, dropping the hose.

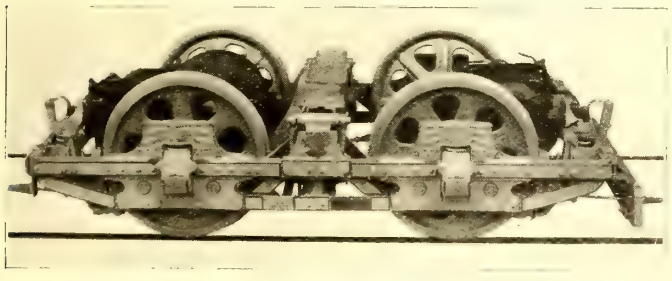
Mr. Howard also manufactures a hose reel mounted on a vertical axis, which, revolving as it does, fills all the offices of a swinging hose reel to those who prefer that type. The automatic draining feature will recommend it to those having hose in places exposed to low temperature.

Although these racks and reels have been on the market but a short time, Mr. Howard states that business is good, that many of the largest street railway plants are being equipped with these devices.



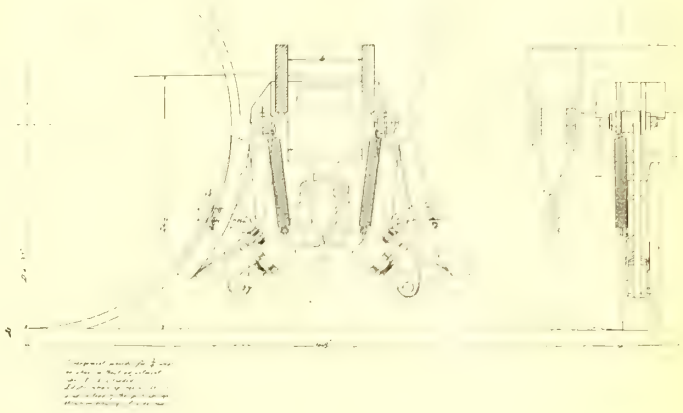
Air Brake with Motor Compressor for New York

During the last month the Third Avenue Railroad Company, of New York, as mentioned elsewhere, awarded contracts to equip the 160 new electric cars, which it will soon put upon its line, with air-brake apparatus of the Standard Air Brake Company. This



AIR BRAKE CONNECTIONS FOR MAXIMUM TRACTION TRUCKS

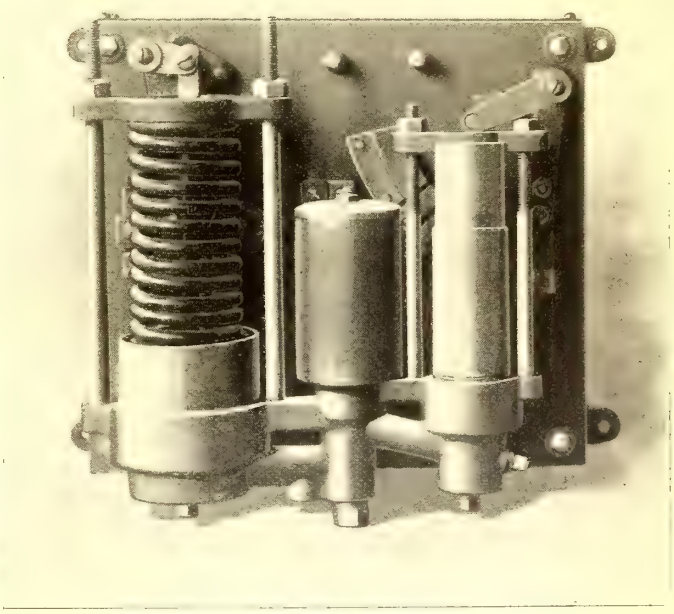
constitutes probably the largest order ever given in this country for street railway air brakes and is a striking commentary on the importance which the air brake is being accorded by electric railway managers. The type of air brake adopted is the independent driven compound compressor with automatic current controller and rheostat. The type adopted has only recently been put upon the market by the Standard Air Brake Company and is illustrated in the accompanying engravings.



MAXIMUM TRACTION TRUCK FOR THIRD AVENUE RAILROAD

As will be seen, it differs materially from previous equipments of this kind. The motor is of a special construction and designed solely to answer the severe conditions of street railroad air braking. It is series-wound, multipolar, entirely enclosed and securely protected against dust and moisture. At full load the speed is

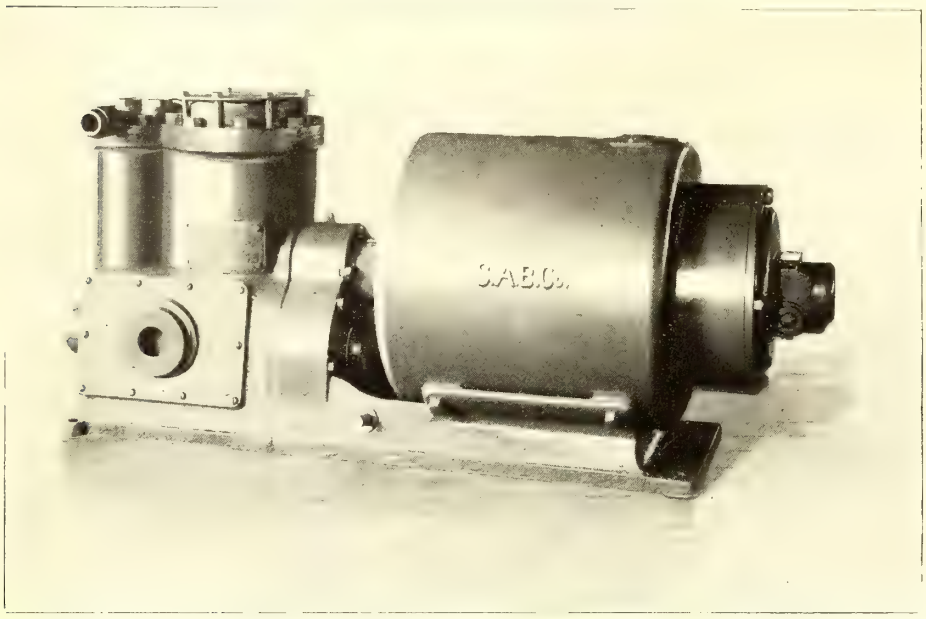
SHORT WHEEL BASE DOUBLE TRUCK FOR THIRD AVENUE RAILROAD



750 r.p.m. The bearings are of ample size and length, self-oiling and self-aligning. The armature is of the type known as iron clad, built up of discs of sheet iron perfectly laminated one from the other, and with grooves punched to receive the windings. The armature core is mounted on a bushing independent of the shaft and keyed to it. This construction allows of expansion and contraction of the armature core without affecting the shaft. The armature coils are of the best cotton covered, soft drawn copper wire, wound on forms, then taped with a special linen tape and laid in mica troughs of the best India mica, in the grooves of armature. The character of the insulation, and the extreme care with which this part of the work is carried out, are sure guards against possible grounding or breaking down of insulation. The pinion, armature and commutator bushing are held in place by keys of the latest design, being a milled half-round key, giving

AIR BRAKE CONNECTIONS FOR DOUBLE TRUCK

the most durability and admitting of the greatest strength of shaft. The brush holders are of good red brass, milled to standard size to receive the brushes. The latter are held in place with adjustable phosphor bronze springs, which are very elastic and can be thrown back to a position where the brush can be removed with perfect ease. The commutator casing is covered with a steel band secured with a self-locking device, and the band is easily removed, giving quick access to brushes, and ample room is provided and unusually large clearances are allowed around the brush holders.



The compressor is of the compound type, and the efficiency shown, working against a pressure of 60 lbs. per sq. in., exceeded

AUTOMATIC CONTROLLER AND RHEOSTAT

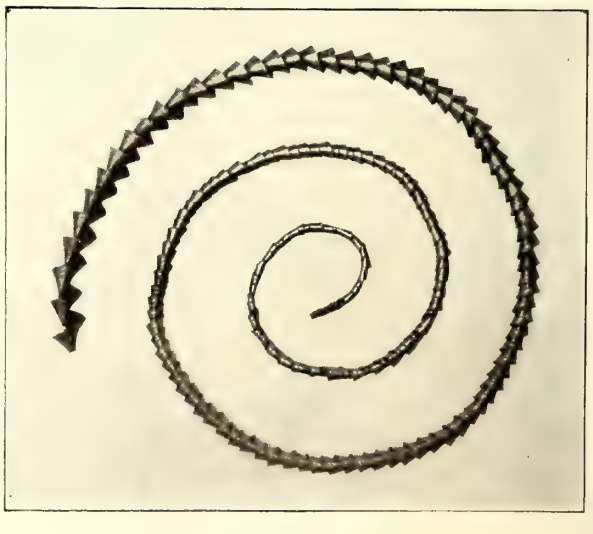
85 per cent. It is bolted to the end of the motor, the crank shaft extending at this end to receive a gear wheel, meshing with a pinion on the armature shaft directly above. The cylinders and upper half of housing and gear case are cast in one piece, carrying one-half of the bearings for crank shaft. The lower half of the housing and gear case, together with the base for motor and

the other half of the bearings for crank shaft are also cast in one piece. The crank shafts and connecting rods are of cast steel. The valve seats and valve bonnets are of brass, the intake valve being in the head of low pressure cylinder, while the intermediate and discharge valves are in the head of the high pressure cylinder.

STANDARD MOTOR COMPRESSOR

The gear and pinion are entirely enclosed in a gear casing, forming an oil chamber, and, when steel pinions are used, can be run in a flood of oil. The housing of the crank shafts is so arranged that it forms a chamber, and all cranks and pistons, together with the bearings, operate in oil. The muffler over the top of the intake valve is cast in one piece and enclosed with a wire screen filled with special woven asbestos cloth and iron wire threads, making a perfect guard against dirt and completely muffling the noise of valves.

The new automatic current controller and rheostat is worthy of special mention. The construction is very durable and simple, and its few parts serve as the best guarantee of its effectiveness. All electrical parts, together with the working devices, are mounted on a slate slab to insure perfect insulation. The apparatus automatically maintains a practically uniform pressure in the air storage reservoirs, and the rheostat forming a part of the machine prevents the sudden starting of the motor against full load. By its use, when the air supplied to reservoirs reaches a predetermined limit, the motor compressor is entirely stopped. As long as air pressure in the reservoirs remains within 8 lbs. or 10 lbs. of the required maximum, the motor compressor remains inoperative. Should the pressure, however, be reduced below the limit, the motor compressor is immediately started (slowly at first and gradually increasing as the resistance is automatically removed from circuit) and continues operating until the maximum limit is reached, when it again immediately stops as before. The motor is series-wound, and when starting with empty reservoirs would naturally "run away;" but, under such conditions, the resistance remains in circuit and is only cut out as the pressure increases. The speed of the motor compressor is at all times automatically controlled by the amount of work required. While the motor compressor is in operation, if for any reason the line circuit is interrupted, the resistance is thrown in circuit with the motor compressor simultaneously with the stopping of latter. When the circuit is again restored, the motor compressor resumes operation, gradually increasing in speed in the way above indicated. The resistance wire in the controller is wound on porcelain tubes secured in the base of the controller, under the slate, giving perfect insulation. The back of the controller is lined with asbestos and covered by a sheet of metal. The whole is then entirely enclosed in an iron casing, fitted with a cover and secured by a lock. The resistance is divided into six steps and seven contact points.



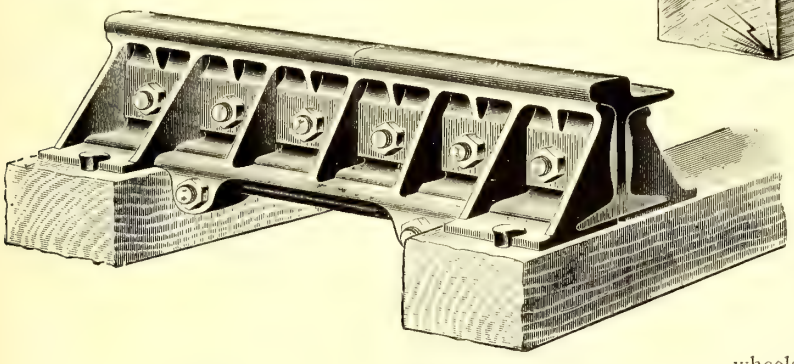
The company will adopt a special method of attaching the brakes to the trucks. Two types of trucks have been adopted for the new equipment, the Peckham 14-B short wheel base truck and the Peckham 14-D maximum traction truck. Of these, 200 of the former and 120 of the latter have been ordered during the past month. The method of connecting the brake to these trucks is quite novel, as will be seen by an examination of the accompanying diagrams. In the case of the short wheel base truck there are two jam cylinders on each truck, and these are connected to a form of toggle joint which brings the shoes in contact with the wheels by an outward pressure. In the case of the maximum traction truck, one jam cylinder is mounted on each truck and connected by a system of levers with the brake shoes. Views of both of these trucks are given herewith. Detail descriptions of them have been published in previous issues.

The independent motor driven compound compressors of the Standard Air Brake Company are built in sizes of 1½ h.p., 2 h.p., 3 h.p., 5 h.p. and 10 h.p. The company also manufactures what is known as its double cylinder, single acting, direct connected, motor driven compressors, and has also four types of axle driven machines. The company's 7½-in. duplex, geared,, axle driven compressor was fully described in the STREET RAILWAY JOURNAL for June, 1898. Since that time a number of improvements have been added and a large number of machines have been placed upon the market.

A test was made of this equipment recently at the factory of the Standard Air Brake Company, at Jersey City, in the presence of a number of railway managers, and the results were pronounced most satisfactory. Besides its factory at Jersey City, the company has a second factory at Trenton, N. J. Both are running full time, twenty-four hours a day, to supply the large demand for air brakes. Orders for these appliances have come from all civilized parts of the globe.

A Long Metal Shaving

The accompanying engraving made from a photograph illustrates a metal shaving recently drilled from a steel rail on the Illinois Central Railroad. With the old-fashioned ratchet drill such a boring would be practically an impossibility. The one shown is from a 13-16 in. hole; it was made without a break, in one

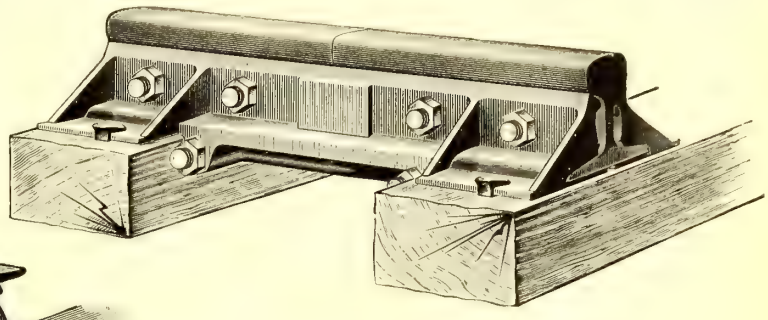


LONG METAL SHAVING

minute and forty-six seconds, and contains all the metal taken from the rail in drilling the hole. It gives proof that the drill which did the work was driven by a continuous feed. The boring was some 40 ins. long and was cut by a Paulus drill manufactured by the Buda Foundry & Manufacturing Company, of Harvey, Ill.

The Argentine-American Commercial Company, of Philadelphia, proposes to establish a warehouse in Buenos Ayres for the exhibition of American goods of all kinds, with a view to increasing the trade relations between the Argentine Republic and the United States. This company will also employ a number of competent salesmen to introduce the American goods.

A New Rail Joint

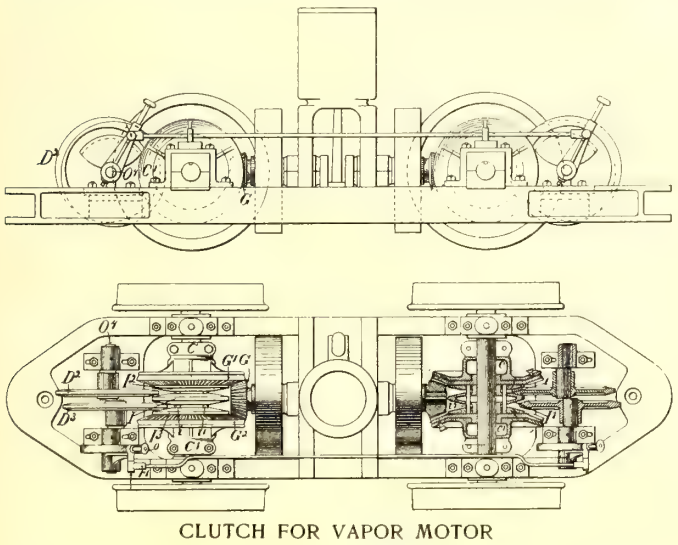


In the accompanying illustrations is shown the Atlas rail joint, which is manufactured by the Atlas Railway Supply Company, of Chicago. The Atlas joint consists of one or two girders whose depth and design make the connection between the rail ends stronger than a section at any other point. When two girders are used, they slip over the rail from either side in such a way that the lower flange is practically enclosed, and presents a broad bearing surface to the under side of the head. In addition to the usual bolts through the web, there are others through lugs on the under side of the joint and passing under the flange. If the single bar style is used the lower flange of the joint is made wide enough to extend under the entire width of the rail. Over the ties the flanges

RAIL JOINT FOR GIRDER RAILS

of the joint are extended so that they serve as rail braces, and the lower flanges of the joint act as tie plates.

A special joint is made for track that is laid with chairs, the joint being deep enough to do away with a chair at that point.



RAIL JOINT FOR T RAILS

New Clutch for Use with Vapor Motors

Since the invention of vapor engines many attempts have been made to apply them to self-propelled vehicles for street railway traction. In systems employing a gasoline or other vapor engine, mounted on the truck or car body and operating continuously at a uniform speed, the main obstacle has, of course, been the difficulty of securing a flexible connection between the engine and the axle for bringing the car to speed from a state of rest, and also for graduating the rate of speed. In 1896 a mechanism was invented by E. Prouty, of Chicago, Ill., that, it is claimed, successfully supplies this demand for a flexible connection.

By the use of a single lever the car is started from rest without jerk or jar, and given any desired speed up to the maximum, and

CLUTCH FOR VAPOR MOTOR

by simply pulling the lever over to the opposite position the car is as smoothly reversed and moved in the opposite direction. By placing the lever in a vertical position the car is stopped, while the engine continues to run as before. At the same time the application of the power to the vehicle is graduated in correspondence with the speed.

The accompanying illustration shows the clutch applied to a truck. F is the beveled pinion on one end of the engine crank-shaft and G^1 and G^2 are beveled gear running idly in opposite directions when the load is off. I is the middle block, fastened rigidly to the axle, and which is beveled ordinarily 3/16 in. to the inch. I^2 and I^3 are beveled discs on one side and smooth, flat surfaces on the other, and while they admit of a lateral movement on the axle they are held by keys or pins, i and i^1, forcing them to revolve with the axle. C and C^1 are the outside discs, that are rigid on the axle, with a flat face lying against the corresponding flat face on the beveled gear. $D2$ and $D3$ are impinging wheels on the eccentric rocking shaft $O4$, $D3$ being shown in effect, G^2 now carrying the load, while G^1 is playing as an idler. By reversing the lever G^2 is freed and G^1 is put into effect, and by placing the lever in a vertical position both gears are freed and play as idlers. The impinging wheels never slip, but revolve by contact with the discs.

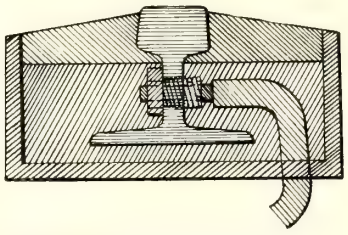
It will be noted that the friction of the discs on both sides of the gear is in the same direction, eliminating all counter friction when applied. Hence, if the clutch is thrown in lightly, it is operative without loss of power to that extent, and will start or move the load gradually. It is stated that in practice the clutch does not heat when run at any degree of slipping pressure. As there is no counter friction there can be no loss by slipping friction, and, it is claimed, as the faces of the clutch do not disintegrate, but wear as an ordinary journal, the force of the power or engine is conveyed to the load without any more waste than would be on the wrist pins and cross head of an ordinary locomotive.

Signal System for Single Track Roads

Williamson & Company, of Allegheny, Pa., manufacturers of the Ramsey signal system, report that this device is giving entire satisfaction wherever it is used, and that it has proven itself entirely efficient in actual operation, covering a period of several years. The large number of high speed single track surburban roads now being built has largely increased the demand for an adequate signal system to prevent collisions and to enable the conductors of cars on different parts of the system to communicate with each other and with the central office. The Ramsey signal system appears to fulfill all these conditions. The latest modification of this device was fully described in the Street Railway Journal for September, 1898.

Massachusetts Institute of Technology

The Massachusetts Institute of Technology has recently made a number of important additions to its laboratories, thus greatly enlarging the facilities for making tests of various kinds. One of the principle improvements is the erection of a new building and the addition of a new tandem compound engine in the engineering department, by which twice the amount of work can be done. Where thirty men formerly worked on one engine and its pumps, fifteen men now work on each engine, giving the men a great deal more experimental work. Various tests are now being carried out on the effect of moisture on timber, elasticity of wood, etc.

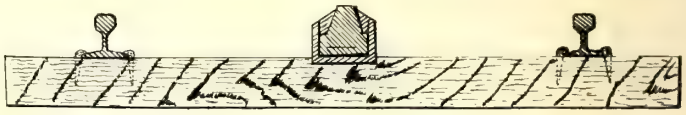


American Institute of Electrical Engineers

The 133d meeting of the institute was held at the Institute Building in New York on the evening of March 22, 1899, President Kennedy in the chair. A paper was presented by M. L. Pupin, of Columbia University, on the propagation of long electrical waves. An interesting discussion followed the reading of this paper. The council decided to hold the next general meeting at Boston during the last half of June, the exact date to be fixed by the executive committee.

Safety Third Rail Railway at Coney Island

During the last month a third-rail electric railway, installed by the Safety Third-Rail Company, of New York, to demonstrate the advantages of its system, was put in operation at Manhattan Beach, Coney Island. The road equipped is the Marine Railway, connecting Brighton Beach and Manhattan Beach, and it is 1951 ft. in length. The track is of standard railroad construction, with 56-lb., 4⅛-in. T rails and stone ballast, and differs from a trolley track only in the absence of the overhead system and in the use of a third rail which is laid on the ties in the center of the track. A standard 500-volt current, taken from a special dynamo located in the lighting station of the Manhattan Beach Hotel, is used.



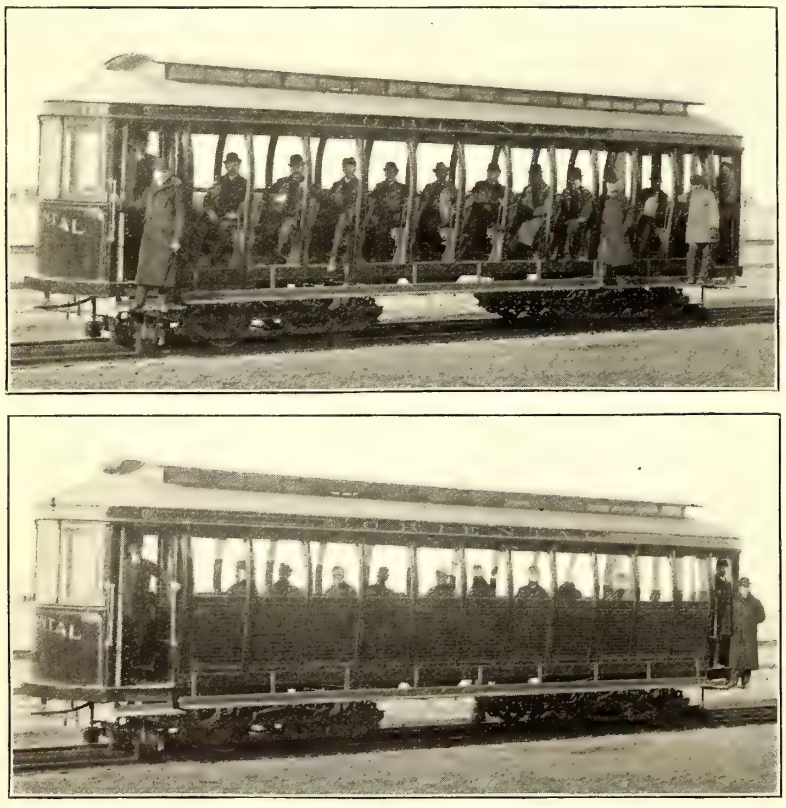
The third rail, which is of standard T section, is of steel, and is laid in alternate live and dead sections insulated from each other. The live sections are 15 ft. in length and are supported at either end by granitoid bases, as shown in the section and side elevation of the third rail construction herewith. The entire rail circuit, including the granitoid pieces, is then enclosed in a creosoted wooden trough, which is then filled with a special form of insulation which is poured in hot. The granitoid insulating blocks also act as section insulators between the live and dead sections, presenting a surface of 1 ft. between the two. The line has seventy-two live sections and seventy-three dead sections, the latter are 10 ft. in length. The height of the top of the third rail above the ties is 5 in. The track rails are bonded in the usual way for return.

SECTION OF THIRD RAIL, SHOWING METHOD OF INSULATION AND CONNECTION TO FEEDER.

The system of connections used is shown diagramatically on page 261. Each live sectional rail is connected to a solenoidal switch which has two windings, one of low resistance wound with coarse wire and another of high resistance wound with fine wire. The former is normally open and the latter is normally closed, connecting its circuit between the sectional third rail and the ground. The car carries a small motor-dynamo of 20-500 volts and a storage battery of ten cells connected as shown in the diagram. When ready to start, the motor-dynamo is driven by the 20-volt battery current, generating at its other end, an e.m.f. of 500 volts. The method of operation is then as follows:

Suppose the car to be over a rail and ready to start. The switch being open there is no connection between the feeder and the car, which therefore can receive no current. The motorman operates the controller and thereby connects the motor-dynamo to the third rail and to the ground and current passes through the fine wire of the switch and causes it to operate. In response to this current

CROSS SECTION OF TRACK THROUGH INSULATING BLOCK



CROSS SECTION OF TRACK THROUGH LIVE OR DEAD SECTION

SIDE ELEVATION OF INSULATING BLOCK

the plunger rises and first makes contact between the main feeder and the rail and then breaks the current of the fine wire winding. The controller is now open and current comes from the feeder through the coarse wire winding of the switch to the third rail and from thence through the car motor to ground, causing the motor to revolve and the car to move. The switch is held shut because of this current in the coarse wire winding. In this closed condition the switch will remain as long as the car is taking current from the section to which the switch is connected. When the car leaves the section, there is no longer any current passing through the switch feeding it and it falls open, first breaking the circuit between the feeder and the sectional rail and second, restoring the circuit from the sectional rail through the fine wire to earth. The switch is then ready for the next car. The car being thus started, the motor-dynamo is no longer needed to operate the switches because the car is provided with two sets of shoes which are con-

DUPLEX CAR, OPEN AND CLOSED

VIEW OF TRACK

nected together and placed sufficiently far apart to span the distance from section to section. The forward shoe as it impinges on a section, subjects it to the full line potential, drawing its source of current from the rail preceding, for the main feeder has already been connected thereto in the manner just described. Once started, therefore, the car becomes independent of the motor-dynamo, for it uses the power house current to operate the switches.

It will be noted that the switch remains closed until the car ceases to take current from the section it controls. It will then fall open from lack of current to hold it up and there is then no

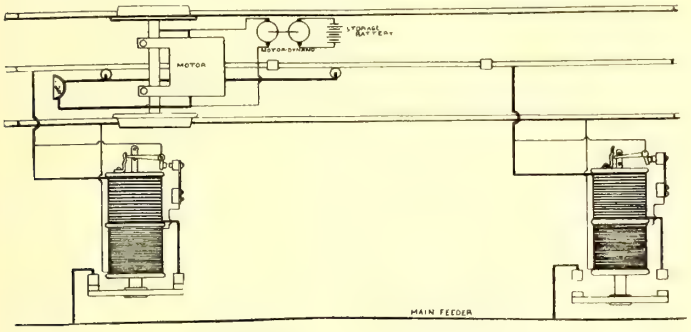


DIAGRAM OF CONNECTIONS

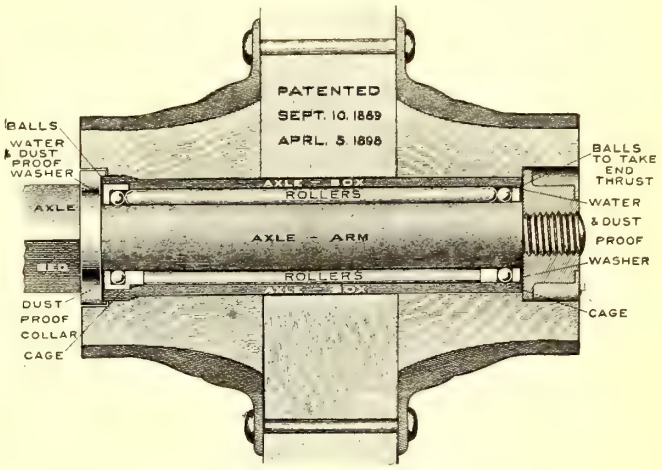
current to break, and hence no arc at the switch jaws, and it is therefore a non-arcing switch.

One side of the motor-dynamo is connected across the motor terminals and ordinarily receives current therefrom, acting as a motor and driving the low potential side as a dynamo charging the ten small storage cells. If, however, the line current should fail, the sides of the motor-dynamo will exchange functions and the high potential side, now a dynamo, will supply current to operate

END VIEW OF CAR AND SWITCH



the switches and light the car. This is the operation also at starting.

The car is of the Duplex type, manufactured by the Duplex Car Company, of New York, and has attracted much favorable comment by its tasteful appearance when open and closed. The engravings on page 260 show it in both conditions. The car is mounted on two Peckham 14-A trucks, equipped with G. E. 1000 motors with standard controller, with the exception that one contact is changed. The car carries ten cells of storage batteries and the rotary transformer required by this system. Both of these are located underneath the car so as to take up no space available for passengers.

To demonstrate the reliability of the system under adverse conditions, the road has been subjected to very severe tests. One of these tests was that of covering the road for a distance of 25 ft. with closely packed and wet snow heaped to a height of several inches above the track, entirely hiding the three rails from view. This condition did not interfere with the operation of the system in the slightest degree and the car glided through the snow without difficulty and was started on the section covered with snow without trouble. Another test consisted of covering the track with dirt, entirely hiding the three rails, after which buckets of water were poured on the track, making a combination of mud and water. This did not in the slightest degree interfere with the operation of the car. The test was carried on under the supervision of Capt. J. McL. Murphy, the inventor of the system, and was witnessed by a number of well-known railway men who spoke in the highest terms of the results secured.

Roller Bearings

A new form of roller bearings for street railway service, heavy road wagons, etc., is shown in the accompanying cut. The device consists of a series of from nine to fifteen rollers, the number varying according to the size of the axle, about ⅜ ins. in diameter.

SECTION OF ROLLER BEARING

These rollers are readily interposed between the axle and the axle box, coming into immediate contact with both. In addition to this, there are balls at the end of each of the rollers, thus reducing the friction to a minimum. It will be observed that the weight is not on these balls, and there is, therefore, no danger of their being crushed. The weight comes directly on the rollers and is evenly distributed throughout their length. The device is manufactured by the Standard Roller Bearing Company, of Philadelphia, and the principal claims made for it are simplicity and strength, cheapness, and a great saving in power.

Exhibits at the Convention

Mr. T. C. Penington, secretary of the American Street Railway Association, has issued the following letter to electric railway supply men, in reference to the exhibits at the next convention:

The exhibits and displays of the supply men are so important a part of our conventions, that the executive committee, in making arrangements for the meeting, have been as mindful of our wide-awake allies and as zealous in providing for their convenience and accommodation as for any other feature of the gathering. The Exposition will be held in Tattersalls, the largest exposition hall in the city. We will have an abundance of floor space with all the light, heat and power required. Every applicant is assured that he will get all the space desired, as our resources in this direction are unlimited. The convention will be held on the second floor of the exhibit hall, all stairways leading up from the inside, thus insuring the attention of all delegates and visitors to the exhibits.

The income from the sale of space will go to the American Street Railway Association. The executive committee of the association has fixed the price at ten cents per square foot, and ruled that no space less than one hundred square feet will be assigned, but applicants may have as many multiples of this quantity as they wish, all in one body. Payment for space should be made to Mr. T. C. Penington, secretary and treasurer of the American Street

Railway Association, 2020 State Street, Chicago, Ill. Application for space should be made to Jas. R. Chapman, 444 North Clark Street, Chicago, chairman committee on exhibits. Please state in your application for space the shape desired, number of feet wide and long, and the committee on exhibits will comply with your request if possible. Cars, sweepers and plows will be placed outside of the building on the street.

It is earnestly requested that all exhibits shall be in place and all work finished by Monday evening, Oct. 16, which is the evening prior to the opening of the convention. The local committee has rented the building from Oct. 10 to Oct. 24, so you can ship your goods early and will have ample time to remove them. Watchmen will be in charge of the building so that exhibits will be safe. All goods should be marked to yourselves, Tattersalls, Chicago, care of H. W. Smith, successor to Anderson Transfer Company, 1618 State Street, sending him bill of lading or advice that you have shipped goods in his care, giving particulars in regard to shipment, and it will be delivered to your space in the exhibition hall. Ship all goods early to insure delivery in time and prepay charges. We hope to have you with us with an extensive display. All articles intended for the exhibition shall be delivered at the building by the agent or owner, and at his expense, but the local committee have made arrangements with H. W. Smith (successor to Anderson Transfer Company) to haul and deliver all shipments to and from the building at low rates if directed in his care. Articles will be placed on your space in the hall if you mark the number of space on your boxes. The number of your space will be mailed you in ample time for shipment. All electrical connections for power and extra lights must be made at the expense of the exhibitor.

We expect a large exhibit, and perhaps it would be in the interest of the exhibitors to make arrangements to have the building open in the evening, as it is well lighted, and the electrical companies expect to make a large display. Space must be applied for by Sept. 1. Assignments will be made as promptly as possible after that date and exhibitors notified of their location. Exhibits of like character will be grouped together and space will be assigned in the order of application. The committee on exhibits will make contracts with carpenters, electrical workers and laborers at regular prices, so the exhibitors will not be overcharged for lumber, labor, etc.

Friday, the 20th, has been set apart by the executive committee for the examination of exhibits. No session of the association will be held on that day and no entertainments of any kind will be given by the local committee, so all delegates will have ample time to call upon you and see what you have to show them.

The headquarters of the association will be at the Auditorium Annex. All our hotels are within a radius of one-half mile and within ten minutes' ride of the hall. They include Auditorium, Victoria, Leland, Great Northern, Wellington, Grand Pacific, Tremont and Sherman. The executive committee advises all who desire room to apply at once, as they will be assigned in the order in which applications are received. The executive committee found our Chicago friends so enthusiastic as to the coming meeting, and so hospitable in their greeting, that success is assured, the location being central and accessible; and the inquiries and information already received being so encouraging an unusually large attendance seems guaranteed. The annual dinner will be held at the Auditorium, Friday, Oct. 20, at seven o'clock, P. M. Tickets will be sold at the actual cost to the association.

The railroads will sell tickets on the certificate plan. Be sure and leave your certificate with the clerk the first day of the convention, when you register; it will be signed, vised and ready for you on Thursday, Oct. 19, 1899.

Please make your arrangements and applications as above noted as promptly as possible.

(Signed) T. C. PENINGTON,
Secretary and Treasurer.

Large Orders for Well Known Engines

The Willans engine, as manufactured by Willans & Robinson, of Rugby, Eng., are being introduced very extensively into tramway power plants. Among the larger orders for engines for this class of service received during the past year may be mentioned the following: Eight engines of 1200 h.p., besides several smaller engines, for the Liverpool Corporation; four of 700 h.p. for Bradford, Eng.; two of 500 h.p. and 250 h.p., respectively, for the City & South London Railway; two of 800 h.p. each for the Brighton Corporation, England, and two of 1200 h.p. each for the Glasgow Corporation.

The manufacturers of this engine report that the orders received during 1898 exceed those of any previous year, and the sales thus far in 1899 continue to show an increasing demand. This concern is now building larger engines than ever before, the standard size for central station work having until recently been about 280 h.p., but within the last few months the size has been increased considerably, until now, 700, 800, and even 1000 and 1200 h.p. engines are not uncommon. To meet the demands of the business, the manufacturers are arranging to greatly enlarge the capacity of their works.

Personal

MR. E. L. SIMONTON, formerly electrician of the Lincoln Electric Street Railway, has resigned.

MR. H. R. McLEOD has left the Portland & Cape Elizabeth Railway Company, of Portland, Maine.

COL. G. W. PARKER has been elected president of the Springfield Traction Company, of Springfield, Mo.

MR. WILLIAM P. GANNON has been elected president of the Syracuse Rapid Transit Railway Company, of Syracuse, N. Y.

MR. JOHN M. BLATT has resigned from the superintendency of the Milwaukee, Racine & Kenosha Electric Railway Company.

MR. EDWIN WARNER has been appointed secretary and treasurer of the Birmingham Electric Railway Company, of Birmingham, Ala.

MR. FREDERICK SARGENT, of Sargent & Lundy, Chicago, has been appointed consulting steam engineer for the Boston Elevated Railway.

MR. EDWARD W. DECKER has left the Portland & Yarmouth Electric Railway Company, of Portland, Maine, of which he was formerly superintendent.

MR. L. C. WEIR has been elected president and general manager of the Weir Frog Company, of Cincinnati, Ohio, in place of F. C. Weir, who died on March 1, 1899.

MR. JOHN CLIFFORD has been appointed superintendent of the Wilkesbarre & Wyoming Valley Traction Company, of Wilkesbarre, Pa., in place of John Meixwell, resigned.

MR. CHARLES F. FRANKLIN, superintendent of the Newburgh Electric Railway Company, has resigned his position to accept a situation as superintendent of the Ohio Southern Railroad.

PROF. A. B. W. KENNEDY, of London, is visiting America with a view to examining American electric railway practice and to render a report to the London County Council upon the results of his investigations.

MR. MAURICE HOOPES, electrical engineer of the Lynn & Boston Railway Company, has resigned that position to take charge of the building of a new railway between Albany and Hudson, N. Y. His place at Lynn will be taken by Mr. William Pestell.

MR. S. W. JAMISON, general manager of the Roanoke Street Railway Company, of Roanoke, Va., has resigned that position, and will be succeeded by George C. McCahan, who has been made superintendent of both the street railway and electric light companies.

MR. F. E. DRAKE, director of machinery and electricity of the American commission to the Paris Exposition of 1900, sailed for Europe on the "Lucania," on March 11. He will spend most of his time in Paris negotiating for several engineering concerns, and in going over the field of the exposition work preliminary to taking up the detail of the final allotment of space.

MR. E. K. STONE, JR., of Quincy, Ill., writes that through the similarity of names, his father's death, which occurred Nov. 28, 1898, has been quite generally misunderstood to be his own. Mr. Stone states that he has sold out his interests in the local road at Quincy, but expects to continue in the same line of business.

AMONG THE MANUFACTURERS

THE E. W. BLISS COMPANY, of Brooklyn, N. Y., is sending out a folder describing the new pattern Bliss inclinable power presses for the manufacture of sheet metal goods.

BRYAN & HUMPHREY, consulting mechanical and electrical engineers, of St. Louis, announce their removal from their old offices to rooms 706-708 Lincoln Trust Building.

FREDERICK J. GRAF, of New York city, states that he has received the highest award for fenders at the American Institute exhibition, held at Madison Square Garden, New York.

THE KEYSTONE ELECTRICAL INSTRUMENT COMPANY, of Philadelphia, has placed its New England office, which is located at 170 Summer Street, Boston, in charge of F. B. Smith.

THE JOSEPH DIXON CRUCIBLE COMPANY, of Jersey City, N. J., is sending out another one of its extremely unique and ingeniously gotten up brochures describing Dixon's pencils for all kinds of use.

THE FALK COMPANY, of Milwaukee, Wis., has secured the plant and business of the Western Gear Company, of Milwaukee, and will continue the manufacture of the gears and pinions formerly made by that company.

THE ELECTRICAL INSTALLATION COMPANY, of Chicago, has secured a contract for all the overhead work for the northeast division of the Brooklyn Avenue Railway, at Kansas City, Mo., which includes 4 miles of double track. The work will be of span wire construction with iron poles.

COMPAGNIE HEILMANN, of Paris, France, manufacturer of electrical locomotives, announces that it has been decided to change the title of the company to the Société Anonyme de Locomotion Electrique. No other change will be made in the status of the company. The Paris office is at 2 Rue Pasquier.

CHARLES A. BROWN and GEORGE L. CRAGG, of Chicago, have recently formed a partnership under the firm name of Charles A. Brown & Cragg for the practice of law, giving special attention to patent, trade-mark and copyright litigation and to the soliciting of United States and foreign patents. With the firm will be connected A. L. Lawrence.

THE DUPLEX CAR COMPANY, of New York, has in operation one of its new cars on the experimental line of the Safety Third Rail Company at Manhattan Beach. The Duplex Car Company, whose offices are in the Postal Telegraph Building, is daily receiving inquiries from street railway companies regarding its new form of car and is also receiving flattering testimonials.

PRESTON, COHEN & CO., of Philadelphia, Pa., have made arrangements for handling the goods of some of the leading manufacturers of electrical and street railway supplies at their Philadelphia office, 1004 Real Estate Trust Building. The members of the new firm have had considerable experience in this line of work, and with their present facilities will undoubtedly make a complete success of their new venture.

THE LOMBARD WATER-WHEEL GOVERNOR COMPANY, of Boston, has received an order for three additional type "B" governors for the plant of St. Anthony Falls Water Power Company, of Minneapolis. These governors are for the three additional units of the four Victor turbines each, which are to be installed. This will make in all ten Lombard governors in the above named plant, regulating forty water wheels.

IT IS ANNOUNCED that the partnership heretofore existing between J. R. McCardell, C. H. West and M. J. McDonald, under the firm name of McCardell, West & Co., was dissolved by mutual consent on March 20, 1899, Mr. West withdrawing from the firm. J. R. McCardell and M. J. McDonald have purchased the entire interest in the business, patents, etc., and will continue the business under the firm name of McCardell & Co., at Trenton, N. J.

FRANK H. MONKS, who is well known as the former master mechanic of the West End Railway Company, of Boston, now the Boston Elevated Railway Company, is doing a large business as expert on street railway properties in all parts of the country. Mr. Monks, by experience, is well fitted for determining the value of street railway properties and making suggestions for their improvement, and numbers among his clients the properties of many prominent lines, as well as general investors.

EUGENE MUNSELL & CO., of Chicago, will open a large mica factory at Ottawa, Can. Extensive buildings on Wellington Street have been leased and it is the intention to forward the mica direct from the mines to the factory, where it will be carefully examined and prepared for shipment to New York. Eugene Munsell & Co. now have establishments in New York, Chicago, St. Louis, Cincinnati, San Francisco, and London, Eng., and the opening of these new works is a good indication of the company's prosperity.

THE GARTON-DANIELS ELECTRIC COMPANY, of Keokuk, Ia., reports that orders for its lightning arresters are coming in almost faster than they can be cared for. During the winter this company had prepared twice as large a stock of arresters as last year, but the spring demand has required it to double its force to keep up with orders. Additional help will be secured, however, and all orders will be shipped with promptness. This company's new catalogue, No. 22, is having a large demand and it may be necessary to issue a second edition.

THE B. F. STURTEVANT COMPANY, of Boston, Mass., is sending out its catalogue No. 96, for 1899, and also a little eight-page leaflet devoted to the subject of mechanical draft. Catalogue No. 96 describes and illustrates the Sturtevant steel plate fans for all kinds of service, and will be of great value to any one needing appliances of this kind. The leaflet on mechanical draft contains among other views, an illustration showing the relative size of a fan and chimney required for the same boiler capacity with mechanical draft and natural draft respectively.

THE WESTON ELECTRICAL INSTRUMENT COMPANY, of Newark, N. J., is sending out its complete catalogue for 1899, of the Weston standard electrical instruments. These instruments are built in an almost unlimited number of sizes, styles and shapes, and for every class of service required. They are made under the most careful supervision and all parts are turned out and fitted by experts in this line. In addition to this, each instrument is thoroughly tested and checked before it leaves the factory, so that the name of "Weston" on an electrical instrument is a guarantee of no mean value.

THE ARCHITECTS AND ENGINEERS Electrical Bulletin for February, which is published by the Sprague Electric Company, is just out in a new cover. This bulletin has been published for some time and contains facts and figures of interest to architects and engineers that cannot be secured in any other publication. The issue for February includes, among other articles, the following: "Automobiles," "Electric Heating, and Surface Contact Electric Railways," by E. H. Johnson; a description of the Sprague multiple system, by C. R. McKay; "Electric Wiring Practice," by Fred. Bathurst.

EDWARD ROBINSON, proprietor of the Wells light, will be one of the passengers on the "Lucania," April 8. Mr. Robinson goes to England and the continent on a combined business and pleasure trip and expects to be absent about six weeks. The Wells light is regarded as the most simple and practical lighting device for use in night construction, for shop work, heating heavy metal, etc., and, owing to the unusual activity in the electric and steam railway fields, the company's business for the season has been the largest in its history. The Klondike has opened up a new field for this device, the company having already shipped twenty outfits there for melting the ground.

THE GENERAL ELECTRIC COMPANY, of Schenectady, N. Y., has published a new catalogue on transformer design and operation which is very complete. Among the recent pamphlets and printed matter issued from the printing department of this company are the following: Bulletin No. 4164, devoted to series enclosed arc lighting with alternating current; bulletin 4163, on alternating current induction motors, type I. S., for single phase, 60 cycle, 115-volt circuits, and bulletin 4165, on small direct coupled generating sets. In addition to the above, folders have been issued describing porcelain clamp insulators, T. H. lamp sockets and receptacles, single pole primary switch and fuse boxes.

ELMER P. MORRIS, 15 Cortlandt Street, New York, has secured the contract for 45,000 ties, 140,000 lbs. copper, 17 miles of this being an improved figure-8 design of wire, 650 flexible brackets, all of the overhead material, 2000 tons girder and T rails, 900 wooden poles, and all of the bonds for the Elmira and Seneca Lake Electric Railway, Elmira, N. Y. Mr. Morris has also closed large orders for iron poles from the Brooklyn Heights Railroad Company, Brooklyn; Union Railway Company, New York; the Columbia Railway and the City & Suburban Railway Company, Washington, D. C.; the New Jersey Electric Railway, Newark; 1100 poles for Plainfield, N. J., and iron poles and copper wire for Phœnixville, Pa.

THE TAYLOR ELECTRIC TRUCK COMPANY, of Troy, N. Y., manufacturer of high grade trucks for electric service, has published a new catalogue describing the various types of trucks which it makes. This company claims to fully supply the demand for trucks that are simple in construction, economical in management and easy riding in service. The wheels, axles and all wearing parts are made interchangeable in both the single and double types and contain only the best materials and workmanship. The catalogue contains an interesting illustration of one method of testing the side frames used in the construction of these trucks. In this test the journal boxes are supported solidly and a pressure of 2160 lbs. was placed on each end of the frame, which endured the weight without the least deflection.

THE VOSE SPRING COMPANY, of New York, reports an increasing demand for its various products. Among the specialties that this company is now producing are rubber center yoke springs for journal boxes of electric cars, the Vose patent rubber and iron core springs, coil and elliptical springs for all standard types of electric trucks, trolley springs and brush holder springs, rubber springs, washers and cushions, rubber blocks for elliptical springs, etc. Gustave Suckow, the genial general manager of the company, is probably one of the best known men in the street railway supply trade. He commenced work with this company when but thirteen years old, and has been with it for over twenty-two years and is largely responsible for the satisfactory business it is now enjoying.

THE SIEGRIST LUBRICATOR COMPANY, of St. Louis, Mo., is receiving numerous orders for its well known automatic oiling system. The Southern Electric Railroad Company, of St. Louis, has installed this system on all the engines in its large power station, and the Metropolitan Elevated Railway Company, of Chicago, has also ordered this device for use on two new Allis engines now being installed. The Metropolitan Elevated Railway Company has used the Siegrist system for both cylinder and engine oil for over four years. The Siegrist automatic oiling system has also been specified by Armour & Company for use on a new ice machine and two new Corliss engines now being installed at South Omaha, Neb. This order is given after eight months' use of the system on the other machinery in the Armour plants.

HEDDEN & WHEELER, of Newark, N. J., manufacturers of varnishes, iron paints, etc., report that the growth of their business in iron paint during the past year has been very satisfactory. This paint meets the approval of everyone using it, and letters of commendation are being constantly received. The paint is well adapted to use on all exposed metal work such as electric railway poles, bridges, etc., and a number of street railway companies are using it in large quantities. Among the latter are the Consolidated Traction Company, of Jersey City, N. J.; Buffalo Railway Company, of Buffalo, N. Y.; Camden & Suburban Railway Company, Camden, N. J.; Portland Railroad Company, Portland, Maine; Middletown-Goshen Traction Company, Middletown, N. Y.; Plainfield Street Railway Company, Plainfield, N. J., and many others.

ARTHUR W. FIELD, of Boston, sole New England agent of the Peckham Truck Company and the American Car Company, has just sold the Boston Elevated Railway Company seventy Peckham Excelsior trucks to be used under the nine bench cars of the American Car Company's make, which he sold last January to the same company, and thirty pairs of Peckham maximum traction trucks to be used under the twelve-bench open cars of the American Car Company's make, which he sold to the Boston Elevated Railway Company in connection with the above. He also reports the sale of eight cars to the Western Construction Company, of New Haven, Conn., to be used on the line of the Ohio Central Traction Company, which owns a 12-mile road extending from Galion to Bucyrus, Ohio. Four of these cars are 26-ft. double truck closed cars, two of which have baggage compartments. The other four are ten-bench open cars. Mr. Field reports over $125,000 worth of business since Jan. 1.

L. E. MYERS, Monadnock Building, Chicago, has just secured the contract for building an 8-mile extension of the lines of the Chicago Electric Traction Company, from Blue Island to Harvey, Ill. Under the successful management of E. R. Gilbert, this road is giving excellent promises. Mr. Myers has also secured the contract for building and equipping the Peoria & Pekin Terminal Railway, 12 miles long at Peoria, Ill. The contract includes a power house with steam and electric equipment of 1000 h.p., car barns, round house, machine shops, office buildings and three passenger stations. A 1200-ft. steel bridge with a 380-ft. draw span will be built across the Illinois River. The contract for this has already been let to the Schultz Bridge & Iron Works. Another steel bridge 150 ft. long will be built across the Kickapoo River. The line will be equipped with both steam and electricity, the steam equipment being used for handling freight, and including fifty coal cars and three 70-ton locomotives. Seventy-pound, 60-ft. T rail and 000 figure-8 trolley wire will be employed.

W. R. GARTON COMPANY, of Chicago, has just been appointed exclusive representative of the Electrical Railway Equipment Company, of Cincinnati, Ohio, for its entire line of specialties in the Middle Western States, Chicago being the headquarters for this territory. The Garton Company will carry a very complete stock of everything necessary for the equipment of electric railways, including motor supply and repair parts. Among other concerns which this company represents are the following: Massachusetts Chemical Company and C. S. Knowles, of Boston, Keystone Electrical Instrument Company, of Philadelphia; Pittsburgh Steel Hollow Ware Company, of Allegheny, Pa.; Empire Lamp Works, Graphite Lubricating Company, of Bound Brook, N. J.; Garton-Daniels Electric Company, of Keokuk, Ia.; Partridge Carbon Company, of Sandusky, Ohio; Billings & Spencer Company, of Hartford, Conn., and it is prepared to make prompt shipments of all the products manufactured by these establishments. The Garton Company is also exclusive agent for the celebrated American incandescent lamp, which is made for all voltages and in all types. The company reports that its volume of business is extremely gratifying and it looks for a still greater increase during the coming season.

THE HARRISON SAFETY BOILER WORKS, of Philadelphia, Pa., reports the following recent sales of Cochrane heaters: Minnesota Iron & Steel Company, 350 h.p.; Dayton & Western Traction Company, West Alexandria, Ohio, 300 h.p; Chase & Company, Boston, 150 h.p.; Sears, Roebuck & Company, Chicago, 100 h.p., special; Douglas & Company, Minneapolis, Minn., 200 h.p.; McGinn & Lewis, Pittsburgh, 350 h.p., special; Avondale Mine, Plymouth, Pa., 850 h.p.; Parke & Lacy Company, San Francisco, Cal., 50 h.p.; Imperial Ice Company, Philadelphia, 100 h.p.; Bland, Bullen & Gund Company, Chicago, 350 h.p.; Liberty Mills, San Antonio, Tex., 200 h.p.; Republic Marble Company, Luttrell, Tenn., 150 h.p.; Pana (Ill.) Modern Electric Light, Power & Street Railway Company, 500 h.p.; Alabama Ship Building & Dry Dock Company, Birmingham, Ala., 3000 h.p.; Pabst Brewing Company, Milwaukee, Wis., 500 h.p., and many others. The company also reports the following sales of Cochrane separators: Pejepscot Paper Company, Pejepscot Mills, Maine, 10-in. horz.; J. D. McRae & Bro., Chicago, 4-in. horz.; Empire State Dairy Company, Brooklyn, N. Y., 4-in. horz.; Nutter & Seabury, Boston, 8-in. horz.; Estey Organ Company, Brattleboro, Vt., 8-in. horz.; Warner Bros., Chicago, 4-in. horz.; La Compagnie Generale Glace Hygienique, Paris, France, 6-in. horz.; Atlas Cement Company, Northampton, Pa., 4-in. horz.; United Shirt & Collar Company, Troy, N. Y., 6-in. horz.; Monessen (Pa.) Steel Company, two 5-in. vert., one 6-in. vert., and one 8-in. vert., also 6-in. horz.; Dover Iron Company, of New Jersey, 8-in. horz.; Dill & Collins, Philadelphia, 6-in. horz.; Fergus Falls (Minn.) State Hospital, 4-in. vert.; P. Cogan & Son, Stoneham, Mass., 4-in. horz.; Walworth Construction & Supply Company, Boston, 5-in. horz., and many others.

New Publications

Fourteenth Annual Report of the Board of Gas and Electric Light Commissioners of the Commonwealth of Massachusetts. Paper. 210 pages, with appendix of 158 pages. Published by Wright & Potter Printing Company, State Printers, Boston, Mass.

This very complete report contains full financial and other information pertaining to the 158 companies, and the gas and electric light plants in fourteen towns and two cities which are under the supervision of the Board of Gas and Electric Light Commissioners.

Expert Opinion of the New Rapid Transit Proposition in New York

[The following letter, written by President Stuyvesant Fish, of the Illinois Central Railroad Company, to Chairman Orr, of the New York Rapid Transit Commission, has just come into our possession, and is so full of valuable suggestions, based on the writer's experience with the extremely interesting transportation problems in Chicago, that we have decided not to postpone its publication until next month, but to give it at once to our readers.—Editors Street Railway Journal.]

ILLINOIS CENTRAL RAILROAD COMPANY, 214 Broadway.
NEW YORK, March 29, 1899.

MY DEAR SIR:

Permit me to add my congratulations to the hundreds which you must be receiving over the success of the Rapid Transit Commission in securing so fair a proposition as appears to have been made on behalf of those controlling the Metropolitan Traction Company, and to submit some considerations, based on a long experience, in respect to rapid transit in Chicago.

Bear in mind that I am in no way interested in any present or prospective line of communication on Manhattan Island, nor have I ever been so interested in any, and that the Illinois Central Railroad Company has now been running suburban trains in Chicago for over forty years.

I.

A hurried reading of the proposition before you, as given in the newspapers, has not enabled me to see that the vital point of speed of ordinary trains is guaranteed.

The title and the reason for the being of your commission require you to exact rapid transit and that of the rapidest kind consistent with safety and comfort. The utter inefficiency of existing means and the failure, in the past, of such means to even keep abreast of the times, much less to meet a growing demand, require that such guarantees of speed should be most strict, and broad enough to cover the needs of the future.

As no such guarantees can be fulfilled if the carrier is hereafter to be burdened with the payment of an excessive per cent of its profits as taxes, or restricted too much in respect to maximum charges, a liberal, broad-minded, live-and-let-live policy should be adopted and adhered to in this respect.

The Manhattan Elevated Railway, which, after all, affords our nearest approach to rapid transit, advertises, in the "Official Railway Guide," the following schedules on Manhattan Island for its express trains:

Second Avenue,
South Ferry to 129th Street:

Miles	8.81
Minutes	40
Miles per hour	13.21

Third Avenue,
South Ferry to 129th Street:

Miles	8.48
Minutes	40
Miles per hour	12.72

Sixth Avenue,
South Ferry to 155th Street:

Miles	10.76
Minutes	49
Miles per hour	13.17

Ninth Avenue,
South Ferry to 155th Street:

Miles	10.07
Minutes	42
Miles per hour	14.39

Including the initial and terminal points, there are advertised as being on the

Second Avenue	27 Stations in	8.81 miles.
Third Avenue	38 Stations in	8.48 miles.
Sixth Avenue	31 Stations in	10.76 miles.
Ninth Avenue	29 Stations in	10.07 miles.

But the express trains stop at comparatively few of these stations.

The number of stops made by their express trains is unknown to me, but, of course, accessible to you.

The speed of the Manhattan Company's other, local, trains is much less.

Now the ordinary or local trains of the new "Tunnel Company" will meet with no competition as to speed of a higher order than that which is or may be afforded by the trains of the Manhattan Company.

It would, therefore, seem necessary that you now require of the tunnel company a guarantee of such minimum speed on its ordinary trains as it can perform and you may deem satisfactory.

The only thing which I have found in the tunnel company's proposition in respect to speed applies solely to express trains, and is as follows:

"No train to be deemed an express train except one which is scheduled to run, and, barring accidents, does customarily run, over its entire route below Ninety-sixth Street at the rate of 20 miles an hour, and for at least 2 miles below Forty-second Street at the rate of 30 miles an hour."

It is not stated that intermediate stops are to be made below Forty-second Street, and from the different speeds offered above and below that street, it is to be inferred none will be made by express trains.

The distance from Forty-second Street to the southern terminus will, if the latter be placed at South Ferry, amount to about 4 miles. Time, eight minutes.

The distance from Ninety-sixth Street to South Ferry will be about 6.75 miles. Time, a trifle over twenty minutes.

While I would deprecate a discussion of details, and do

not advocate trying to bind the tunnel company too strictly, I beg to submit from the printed schedules of the Illinois Central Railroad Company what is being done in Chicago.

The plant comprises, in addition to side tracks, the exclusive use of two main, or running, tracks, from the initial station, Randolph Street (in the business center) to the next station, Van Buren Street (64-100 of a mile), four running tracks thence to Sixty-seventh Street (8.21 miles from Randolph Street), and two running tracks thence out of town.

There is a local service stopping at every station (seventeen stations in 8.21 miles, from Randolph Street to Sixty-seventh Street, inclusive), and also an express service. Both start on the same tracks from Randolph Street Station, each stops at Van Buren, and the express trains run thence to Hyde Park (6.38 miles from Randolph Street) without stopping, and thereafter make various stops.

ILLINOIS CENTRAL R. R.

Local Suburban Trains.

Randolph Street to Douglas Station:	
Miles	4.01
Stops at all stations	8
Minutes	13
Miles per hour	18.51
Randolph Street to South Park:	
Miles	6.88
Stops at all stations	14
Minutes	22
Miles per hour	18.76

ILLINOIS CENTRAL R. R.

Express Suburban Trains.

Randolph Street to South Park:	
Miles	6.88
Stops	4
Minutes	13
Miles per hour	31.75
Van Buren Street to Hyde Park:	
Miles	5.74
Stops	2
Minutes	9
Miles per hour	38.27

I have, throughout this letter, included the initial and the terminal stations; the express trains make no intermediate stop between Van Buren Street and Hyde Park

The motive power used by the Illinois Central consists of steam locomotive engines, most of which were built many years ago. If the tunnel company is to be tied down to electricity as a power, it cannot, in the present state of the science, be required to make the speed of our trains. We believe, however, that before long it may become possible to move trains by electricity on our schedules, and we have been carefully watching developments in that direction for many years.

On the other hand, the use of electricity as a motive power, in an underground tunnel, will admit of thoroughly heating the stations and platforms, and of using, throughout the year, side-loading cars. We found, during the World's Fair, that the use of such cars effected a great saving of time at stations.

Without professing to know, I should guess that the tunnel company could safely covenant to put in stations averaging about half a mile apart (those of the Manhattan Company averaging a little less than one third of a mile apart), and to run their local trains at a minimum speed of 15 miles per hour, including stops at each, from Forty-second Street south, and also to guarantee a minimum speed of 17 miles per hour, including a stop at each station for the whole distance from Ninety-sixth Street to the southern terminus.

This would give from Forty-second Street to South Ferry a local schedule of sixteen minutes, and from Ninety-sixth Street to South Ferry one of twenty-seven minutes, with corresponding time from intermediate points.

Unless from and to all stations something faster than the so-called express service of the Manhattan is guaranteed and furnished, the tunnel company will neither furnish rapid transit nor be able to survive in competition with the Manhattan.

A guarantee of such speed will prevent an amalgamation with the Manhattan far more effectual than any statutory prohibition, which, after all, is subject to repeal. It will also stimulate the Manhattan to do better, and in my judgment to fare better thereby.

II.

The right to charge an extra fare up to not exceeding ten cents on express trains should be granted, (*a*) in order to prevent those trains being overcrowded by passengers wishing to ride only from one station to the next and incommoding those performing a longer journey, while saving but a fraction of their own time; (*b*) in order to induce the carrier at all times hereafter to keep up that service to the highest standards of safety, efficiency and speed, and thereby make life livable in the upper part of Manhattan Island and the annexed district; (*c*) because the length of the journey, 6.75 miles now, and potentially much more, justifies the charge, especially in view of the tremendous verdicts now so often awarded in personal injury cases, and the expense to which carriers are put through the wiles of shyster lawyers and perjured witnesses in such cases.

Disregarding persons of ample means, to whom the extra five cents each way *per diem* or $36.50 a year is of no consequence, there are occasions in the life of all, except the absolutely penniless—festivals and funerals, times of illness and complete exhaustion, the necessity to catch a train or meet an appointment—in which they would gladly pay five cents for extra comfort and speed in transit. That our civilization and methods of life have advanced to this point is shown by the universal use of sleeping, dining and drawing-room cars on railroads, of providing staterooms as well as mere sleeping berths on all our river and sound steamers.

That the public will gladly pay an extra fare for higher speed was demonstrated in Chicago in 1893, although as a people we were all then economizing severely.

This is made clear by the following extracts from published reports.

Annual report of the Illinois Central Railroad Company for the year ending June 30, 1894, page 1:

"During the six months, from May 1 to Oct. 31, 1893, there were carried, at a uniform fare of ten cents for a journey of over 9 miles, 8,780,616 passengers on the special World's Fair trains, without serious injury to any of them. In the regular suburban trains there were carried during that period 9,358,695 passengers, and the travel in the other passenger trains was also unusually large. The universal satisfaction with the facilities afforded, as expressed by the public through the press and by the directors of the World's Columbian Exposition in formal resolutions, redounds highly to the credit of the service and of the officers and employees engaged therein. The fact that the fare charged by the company was double that of its principal competitor, the elevated railway, demon-

strates that the public are willing to pay reasonable rates for adequate service, when performed with promptness, safety and comfort to the passenger."

Mr. H. N. Higinbotham, president of the World's Columbian Exposition in his report to the board of directors of that corporation, dated Jan. 1, 1898, states, at page 306, that the Illinois Central Railroad Company estimated the number of passengers carried upon its trains between the city and the fair as follows:

Express or special World's Fair trains	8,779,393
Local suburban trains	9,559,791
Other trains	1,003,600
Total by I. C. R. R.	19,342,784
And on the next page (307) he gives the number landed in the fair grounds by the elevated railroad as	4,352,409
Dividing the number carried by the Illinois Central by two, so as to get at the actual number of passengers brought to the fair, we have..	9,671,392

From which we must infer that at that time and place two-thirds of those who traveled by rail preferred to pay ten cents for a quicker, instead of five cents for a slower, service.

The initial stations of the Illinois Central Railroad, and of the elevated railway referred to, were within about a quarter of a mile of each other, and the latter had the more central location. The elevated also enjoyed the advantage of picking up passengers at many intermediate stations, which the Illinois Central could not do on its special World's Fair trains, but only on its regular suburban trains, and to a very limited extent, if at all, on its other trains, referred to by Mr. Higinbotham.

III.

At the risk of getting into details, let me also suggest that the tunnel company be required to find a seat for each passenger. This can be done. It was done, with few and rare exceptions, all throughout the summer of 1893 in our World's Fair trains. It is done daily on the London underground railways, indeed on all English railways with rare exceptions. The use of side-loading cars makes this possible, and it was largely from my experience while traveling abroad that I insisted on the use of that form of car for that special service. It also has the merit of economy of space by giving a much greater seating capacity in proportion to length of train, and consequently of platform. The latter will prove a vital consideration to the tunnel company.

IV.

You have doubtless gone too far to now take up one more suggestion which has been "borne in" on me.

As yet electricity has not been applied in such a way as to give a service equal in speed to that furnished by the Illinois Central in Chicago by using steam. After the most careful, painstaking and patient investigation, we have been forced to adhere to the use of steam, although anxious on many accounts to substitute electricity.

In a tunnel, steam would be intolerable, witness the London underground steam railways.

While I believe electricity can be hereafter so used as to develop schedules about equal to those which we now have in use in Chicago, there is as yet nothing to show that better can ever be done through the use of electricity. Our investigations teach us that with each added unit of speed the cost increases more rapidly where electricity is used than where steam is used.

When your commission began its labors, and even when it formulated and promulgated its plans, the success of the underground trolley had not been demonstrated here in New York. You therefore turned to an underground railway as the only solution.

If not too late, might I suggest at least the consideration of the following plan:

The city has been for many years widening West Street, and has the similar improvement of South Street in view. Why not build on each of these streets (widened) a four-track elevated railroad on which express and local trains can be run as fast as are those of any railroad, and with the same indefinite possibilities as to speed in the future?

In order to avoid the long bend of the East River, which culminates in Corlears Hook, the line on that side of town might leave South Street in the neighborhood of Pike, run through private property to the southern terminus of Essex Street, along that street (widened) until Avenue A is reached, and thence up that avenue.

The other line on the west side might take up the general course of Eleventh Avenue, or possibly Twelfth.

Roughly speaking, the distance between Avenue A and Twelfth is a trifle over 2 miles.

Given two such railroads as are herein suggested, with an express service on each at the rate of at least 40 miles an hour, and local service at at least 20, and trolley lines across town on suitable streets, making 6 miles an hour—as the distance from the Battery to Harlem Bridge is less than 9 miles—one could go from any central point down-town to his home on Manhattan Island below 130th Street in twenty-three and one-half minutes, as follows:

Battery to Harlem,

Express 9 miles at 40 miles per hour.... 13½ minutes.

Across town,

Trolley 1 mile at 6 miles per hour..... 10 minutes.

Total ..... 23½ minutes

This would be something worth having.

The New York Central & Hudson River Railroad might accept the use, during the night, of two tracks on the west side line, from its depot in St. John's Park, to, say, Thirtieth Street, and give up its tracks in Eleventh Avenue and other streets south of, say, Thirtieth Street.

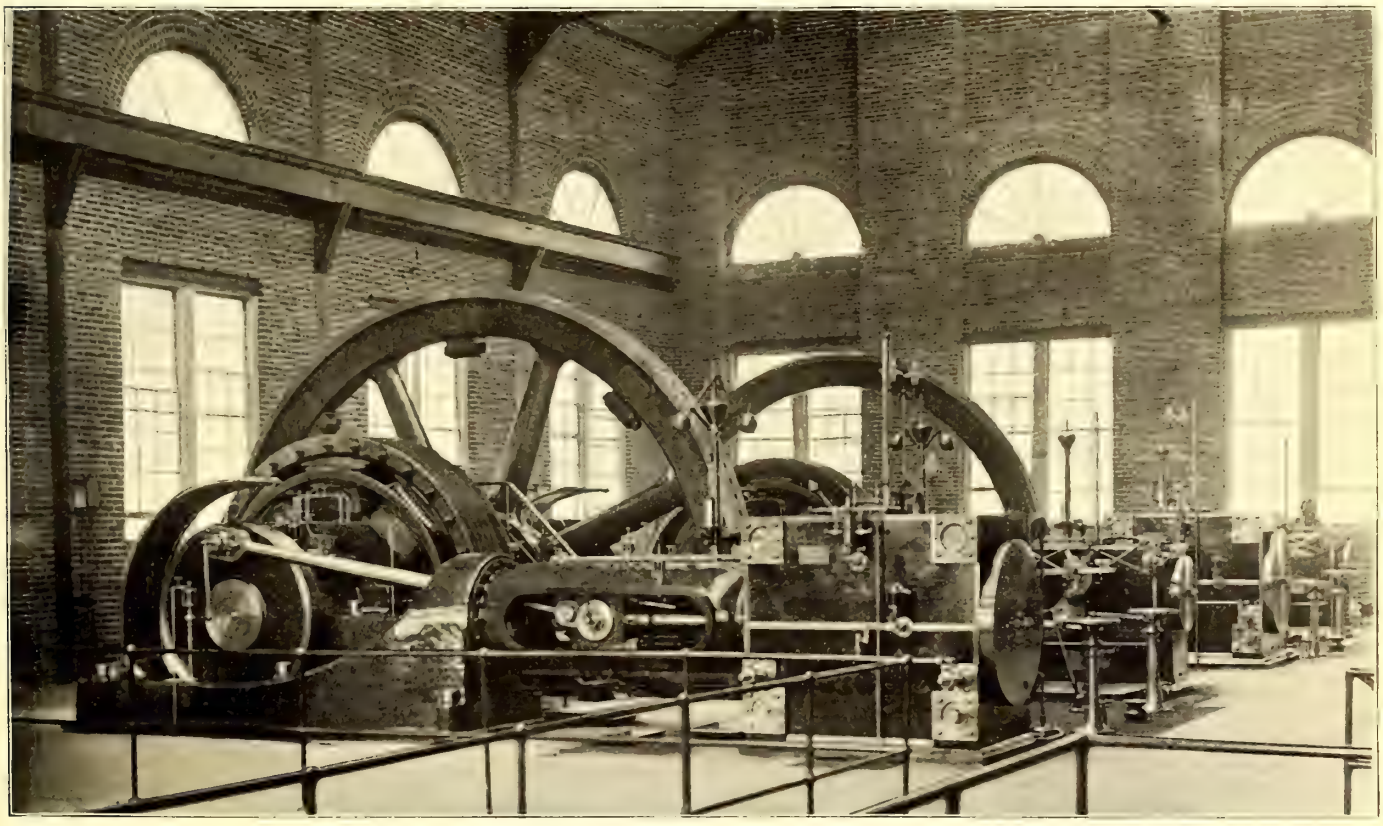
The use of the remainder of two tracks for freight purposes during the night would prove a great source of revenue, relieve our congested streets, make property along both lines valuable for storage purposes and equip this city, as it never can in any other way be equipped, to handle freight cheaply and promptly in competition with other ports and cities.

The magnitude of the interests involved and the possibilities now in sight must excuse so long a letter.

With renewed congratualtions and best wishes for an ultimate, complete and final success, believe me,

Very respectfully yours, Stuyvesant Fish.

To the Hon. Alexander E. Orr,
Chairman of the Rapid Transit Commission.



Street Railway Journal

VOL. XV. NEW YORK AND CHICAGO, MAY, 1899. No. 5.

ANALYSIS OF THE OPERATION OF AN INTERURBAN RAILWAY

The district around Cleveland, Ohio, has become widely known from the number and extent of the interurban electric railways which radiate from that city as a center. The growing number, throughout the country, of railways of this character makes a study of the results secured on some of the older interurban lines a particularly interesting problem. The subject differs in a number of particulars from that of the ordinary street railway, owing (1) to the distance over which power is transmitted before reaching the cars, (2) to the size and weight of the cars operated, and (3) to the high speeds attained. The road selected for study in this article is that of the Lorain & Cleveland Railway Company, one of the more recent of the Cleveland interurban lines. The length of this road from Rocky River, the terminal of the Cleveland City Railway, to Lorain, is 18.5 miles. The track is built over private right of way. There are practically no grades or curves. The schedule running time between these terminals is three-quarters of an hour, and as there are numerous stops, a speed of from 45 to 50 miles or more is often made over a considerable portion of the route. To keep up the schedule it is not only necessary for the cars to make the high speed mentioned, but also to accelerate rapidly. For this reason, each car, which weighs about 22.5 tons, is equipped with four General Electric 50-h.p. motors. Upon reaching the eastern terminal of the line at Rocky River, the cars pass over the tracks of the Cleveland City Railway Company, a distance of 8.5 miles, to the Public Square in Cleveland. On this portion of their route the cars are supplied with current from the power station of the Cleveland City Railway.

During the winter months, the cars operate on an hourly schedule, and during the summer run every half hour. When running every hour there are only from two to three cars at any one time between Rocky River and Lorain, which is the section fed from the power house of the Lorain & Cleveland Railway Company. When the cars are run on the half-hourly schedule, there are from four to five on this section, with the addition often of excursion cars. It is very evident that with a few cars, each equipped with four motors geared for high speed, and starting with a rapid acceleration, the fluctuations of load in the power house must be large, and the machinery installed must necessarily be designed for a wide range of load, and be reliable when operating under large overloads.

INTERIOR OF POWER STATION, LORAIN & CLEVELAND RAILWAY

ROAD AND LINE WORK

The road being on private right of way, the roadbed was built similar to steam road practice, being ditched on

each side and gravel ballasted. The ties are of 6-in. x 8-in. x 8-ft. oak, spaced 24 ins. on centers. The rails are 70-lb. A. S. C. E. standard, with suspended joints and standard four-bolt splice bars. The sidings are 1500 ft. long, with combination spring and throw switches, supplied by the Cleveland Frog & Crossing Company, and fitted with regular steam railroad night and day signals. The curves into these sidings are very easy, so that the cars run into the switches and out again at nearly full speed, with very little swaying. The overhead material is very heavy in all its parts. The poles are 30 ft. 7 ins. in height, with all poles on curves trussed to an anchor behind them, and all poles are braced with a 4-in. x 6-in. x 8-ft. brace placed against the pole about 4 ft. above the ground, and

EXTERIOR OF POWER STATION

the other end against a 4-ft. stake driven with a piledriver. This has been found necessary, as the two No. 000 trolleys suspended over the track make a very heavy load on the cross suspension. It was found almost impossible to keep the poles from springing in without this additional brace, but by means of it the line has gone through an exceptionally hard winter and the soft weather of the spring with very few repairs.

The line extends 12 miles east from the power house and 6½ miles west. The feeders are all of 300,000 c.m., one going 11 miles east, one 10 miles and one 9 miles; and one going 2 miles west, and one 5 miles. By using the double trolley all overhead switches are avoided, so that the cars enter and leave the turnouts without danger of the trolley leaving the wire.

In this connection it is interesting to note that on account of the high speeds and large current taken from the wire the tension of the trolley against the wire has been fixed at from 35 lbs. to 40 lbs., which is much higher than common practice. The trolley wheels are 6 ins. in diameter, with ⅝-in. pin, 2 ins. long, but they are now being changed to wheels 7 ins. in diameter. The life of trolley wheels will not exceed one week, which shows the excessively hard usage to which they are subjected.

ROLLING STOCK

The car equipment at present consists of ten regular passenger cars and two combination passenger and baggage cars. These are equipped with Brill No. 27 trucks, and weigh about 4800 lbs. each. The wheels are 33 ins., with 2⅝-in. tread and 1-in. flange. As electric brakes are used, which are applied direct to one wheel of each pair, the wheels themselves differ in weight, the brake wheel weighing, when new, 520 lbs., while its companion weighs 460 lbs. The motors have thirty-three teeth on the pinion and fifty-two on the gear, which gives a ratio of 1.579.

The car bodies are also of Brill make, and are 34 ft. 6 ins. long and 42 ft. 6 ins. over all, 8 ft. 4 ins. wide, and 12 ft. 6 ins. from track to trolley base. Each car has a telephone with extension rod, for connecting at the contact boxes placed every quarter of a mile along the line, and there are also stationary telephones at every switch, at the ends of the line, at the power house, shops and superintendent's residence.

To carry out the analogy of the steam road practice still further, the cars are equipped with regulation railroad signals. Each car runs a total of 340 miles per day, 240 of which is on the company's tracks, the rest being in the city limits. This gives a total of 720 car miles per day on hourly service, which requires three cars, and 1440 car miles per day on half-hourly service, which requires six cars.

A record of the current and voltage of the car gave an average for one trip of 140 amps. and 565 volts. The record of speed test taken at the same time gave as follows:

LORAIN & CLEVELAND RAILWAY, SPEED TEST, DEC. 30, 1898.

GOING WEST	Distance	Time	Miles Per Hour
Lv. Rocky River double track....12:10.5	3.56	5½ min.	39

Lv. Dover 2:21	3.84	6 "	38.5
Ar. Double Track 2:27			
	16.28	23m.	43.8

Increased distance going east over that going west is due to including the length of two switches on the trip east which were not counted in on the trip west.

This was a special test, and was not taken under operating conditions, as no stops were made between switches to take on or let off passengers. The records show a maximum of 55.5 miles per hour from Avon Beach Park to Sheffield switch, and a minimum of 38.5 miles per hour from Dover switch to Rocky River double track. The first is a straight, level track going west from the power

house, and the latter is the last stretch before reaching the city tracks, and contains two trestles, a drop under the Nickel Plate track combined with a reverse curve, all of which necessitate slowing up.

Referring to the power house report for week ending Jan. 1, 1899, the kw. hours for Friday were 2450, and the car mileage 720, which gives an output of 3.40 kw. hours per car mile, and at the rate given, of 6.4 lbs. of coal per kw. hour, this requires 21.8 lbs. of coal per car mile.

The average for the week was 823 car miles per day and 3227 kw. hours, which gives 3.9 kw. hours per car mile, and 21.5 lbs. of coal per car mile.

POWER STATION

The power station was illustrated and described in the STREET RAILWAY JOURNAL for April, 1897, and was then in course of construction. The plant was put in operation on Oct. 1, 1897, and has given very satisfactory results. The superintendent states that at no time has any part of the machinery had to be stopped because it was out of order, and that during the first year there was no expense for repairs.

The power house is located on the shore of Lake Erie, on a bluff, the top of which is about 22 ft. above the lake level. In order that the coal should fall by gravity from the coal bunker into the furnace, it was necessary to excavate about 16 ft., the excavation on the bluff side being carried right out to the beach.

The coal cars are run up an incline which brings them about 12 ft. above the ground level. The coal drops through the bottom hoppers in the cars into the coal storage. From the storage bins it passes through inclined chutes into the hoppers of the Murphy stokers. The inclined chutes are suspended from scale beams, and each chute load is weighed by Fairbanks scales. The average load is about 500 lbs. The ashes are removed from the pits by manual labor, as it was not considered advisable to install ash conveyors in a plant of this size.

The boilers now in place are four 300-h.p. Stirling boilers. The stack is of brick, 100 ins. in the clear, and 200 ft. high. In the breeching is a damper controlled by a Locke regulator. The water fed to each boiler is controlled by a Thomas boiler feed governor, and on each boiler there is also a Reliance column with high and low water alarm. In the pump pit are two Blake vertical condensers, and a Blake pump for fire and water works service, and which pumps to a 50,000-gal. tank located next the Park system. There is also a small Blake pump which draws from the hot well and discharges into a Stillwell & Bierce open heater; this pump is automatically governed by a Fisher governor. The water is drawn from the heater and fed to the boilers by either one of two Blake outside packed plunger pumps; these are also controlled by Fisher governors. The fire service pump and these two feed pumps are cross connected, and the low service pump drawing from the hot well is also cross connected with one of the feed pumps.

The water in the condensers is obtained through a 20-in. pipe, leading from the cold well outside the building. From the condensers the overflow discharges into a 20-in. pipe, and from the bottom of the pipe leading to such discharge a smaller pipe leads to the hot well.

The steam from the boilers passes through semi-circular bends, each of which has two valves, to a 20-in. header, and thence through Cochrane separators to the high pressure cylinder of the engine. A butterfly valve is placed in each line, and if the speed of the engine increases more than 10 per cent above the normal, the special governor operates this butterfly valve, shutting off steam from the engine, and at the same time making electrical connection which trips the generator circuit breaker on the switchboard. This prevents a flow of current from the switchboard to the generator, which would tend to make it act as a motor. This device was installed at the suggestion of Mr. Wason.

Each engine is a 20-in. and 36-in. x 48-in. C. & G. Cooper cross compound condensing engine, fitted with double eccentrics, and with Tripp's metallic packing. A Musgrave column is used in connection with the sight feed lubricator for the cylinders, and hand pumps are also provided. From the engine the steam passes through a Cochrane exhaust separator to the condenser, with a Blake relief valve in the connection to the atmosphere.

BOILER ROOM AND COAL SCALES

There is a complete system of lubrication of all machinery by gravity pressure from tanks in the boiler room above the boilers. These tanks are fed by pumping from barrels, or a Cross oil filter placed on the floor below the engine room floor and between the engine foundations.

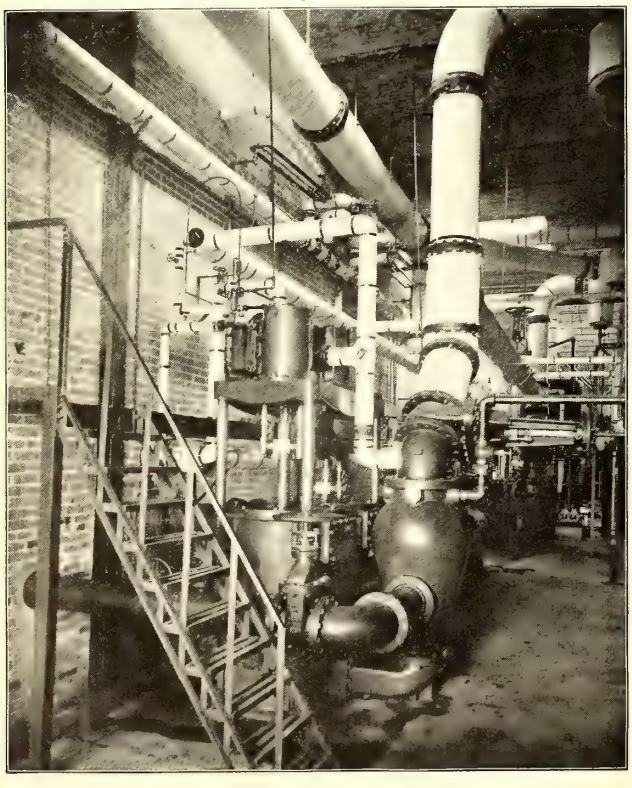
The high pressure piping is all extra heavy flanged, tongued and grooved, and with copper gaskets. It is covered with Keasby & Mattison's magnesia sectional covering. The low pressure pipe is standard pipe covered with magnabestos. The valves are Crane extra heavy bronze seated, and all the larger ones are by-passed. The angle and globe valves are Jenkins'. The water of condensation from all the live steam piping is returned to the boilers by the Holly gravity system.

The generators are two 400 kw. Siemens & Halske, with outside armature and separate commutator. The switchboard has the usual number of instruments, those for measuring the current being of the Weston type. In ad-

dition there is a General Electric recording wattmeter and a Bristol recording voltmeter.

On the gage board there are, in addition to the usual gages, a recording steam gage and a recording draft gage, both made by the Bristol Company.

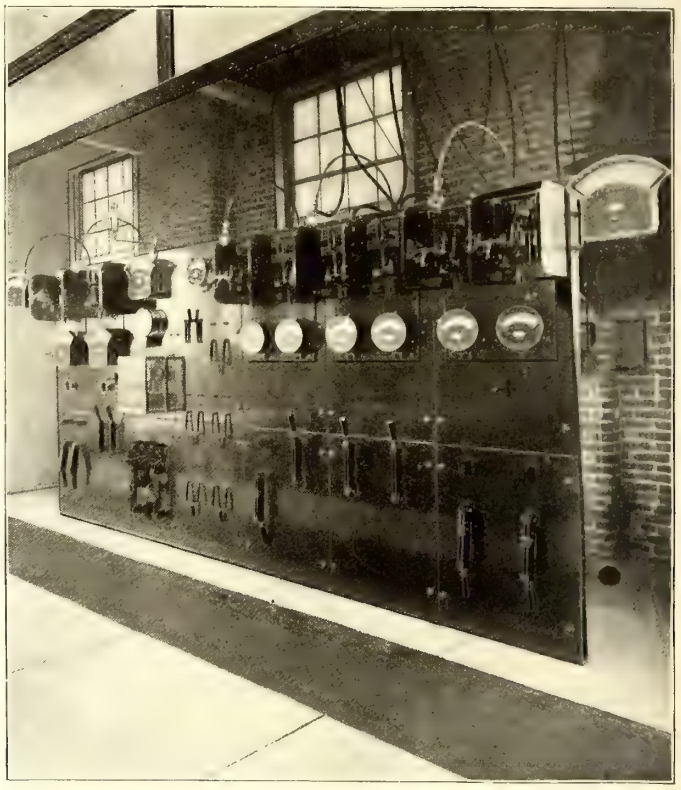
The traveling crane has a capacity for 15 tons and has two 10-ton trolleys, each fitted with triplex blocks. It was built by the Cleveland Punch & Shear Works.



The building is a self-supporting steel structure, having steel roof trusses with steel purlins, the trusses resting on steel posts built into the brick walls. The floor of the engine-room is concrete, resting on hollow tile and supported by steel beams. The flooring between the engine foundations and the pump pit in the boiler room is concrete.

The labor in attendance on the plant consists of two engineers and two firemen and one man who unloads coal, cleans up the plant and acts as a general assistant. The chief engineer, one foreman and the general assistant are on duty during the daytime, and the second engineer and firman at night. These men will still be able to take care of the plant after it has been largely increased.

OFFICERS AND CONTRACTORS



After a considerable portion of the civil engineering in connection with the road had been completed, and the equipment of the cars decided upon, the company engaged E. P. Roberts & Company to design the power station and supervise its erection. Prominent members of the company at that time, as at present, were B. Mahler, Henry A. Everett, E. W. Moore, and C. W. Wason, all well known in electric railway circles. Mr. Wason also acted as consulting engineer for the road.

E. P. Roberts & Company engaged as architect J. N. Richardson, and to design and inspect the steel work and the steel used in the boilers, the Osborn Company. J. N.

VIEW OF PUMPS

Richardson also designed the car houses for the company, and the Osborn Company inspected the steel for the track and designed some of the bridges. The building contractors were L. Dautel, for the mason work; J. W. Vanderwerf, for the carpenter work, and the Forest City Wire & Iron Company, for the structural steel. The piping contractors were Chafer & Becker, who had all the large pipe furnished by the Crane Company, of Chicago, who made

SWITCH BOARD

the piping in accordance with the drawings of the engineers.

TEST OF POWER PLANT EQUIPMENT

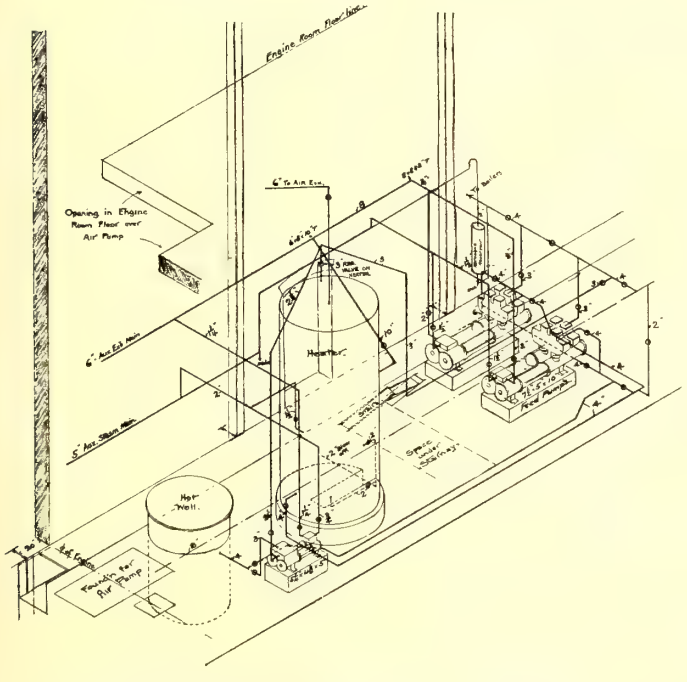
The following is the result of a test made upon the plant. During the time of the test the line was operated on a one hour schedule, by three cars running between the Puplic Square, in Cleveland, and the bridge at Lorain. This schedule was such that one car was on the Cleveland City Railway Company's line all the time, leaving only two regular cars to be supplied with power by the power house. In addition, there was a work train on the road, which sometimes took more power, for short intervals, than a regular car. The time table was so arranged that four cars were used with three crews, one car being kept at the Lorain end for inspection. Thus, a crew would bring in a car at the Lorain end, leave it there and take the car that had been at that point. This, of course, necessitated the running of this extra car to Lorain in the morning and back to the car house at night, a total distance of about 12 miles.

The first test, Feb. 12, 1898, was with two boilers feeding one engine, the generator connected to which supplied current for the regular operation of the line. On the second test, Feb. 14, 1898, the same engine as on Feb. 12 was used to supply the line, and the second engine was run on a steady load provided by a water rheostat. The steam used by these two engines could not be supplied separately, as there was no valve permitting this to be done.

The objects of the two tests were, first, to get the running efficiency of the plant; and, second, to obtain the efficiency of the engines and generators, under a full rated load. In order to accomplish this, it was necessary to obtain the variable load each day and to apply the results obtained on the test for variable load on the first day, to the variable load on the second, and to subtract such figures

from the totals obtained for variable and constant load and thereby obtain the values for constant load.

Although it was necessary to make assumptions as to certain steam consumptions by auxiliaries, it is thought that the results obtained are very nearly accurate, and sufficiently so for all practical purposes. That they are very close is proved by the fact that on the curve of performance for seven months the curve passes through the point obtained at the test, as described later. However, because of the assumptions made, it must not be thought that the engine performance at full load may not have been somewhat better than stated, and furthermore, it must be remembered that the cylinder ratio was for variable load, and therefore that the results at steady and rated load could not be as good as if designed for operation under such conditions. The principal value of the results of the tests is in showing the difference in efficiencies at rated load and at a small and variable load, and the test, taken in connection with the curve of daily performance, is of value in showing the result of increased average although greatly varying load, on the steam and fuel consumption.

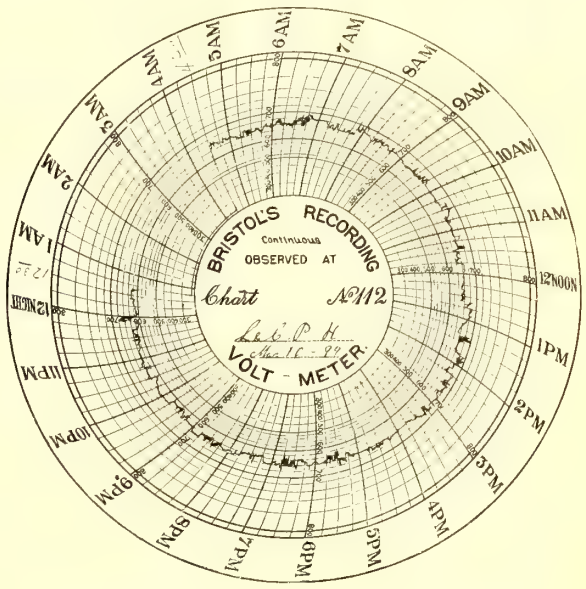


In the data following the tabulation, the numbers refer to the corresponding numbers in the tabulation.

INSTRUMENTS USED

All the gages, indicator springs, and electrical instruments were carefully calibrated by reference to standards.

The coal was weighed in the steel chutes, regularly in use, which are hung on Fairbanks scale beams. These scales were all tested by weighing a known weight on the test scales, and then hanging it on to the chute belonging to the scales to be tested. These scales are tested very closely, and proper correction was made in the coal weights for all differences.



A large tank with an inverted funnel top, and a neck about 10 ins. in diameter, had been especially prepared for weighing water. This tank was filled from the service line by a 3-in. pipe closed by a quick acting lever valve, and

ISOMETRIC DIAGRAM OF PUMP CONNECTIONS

was emptied into a somewhat larger storage tank by means of a 4-in. pipe closed by a quick acting valve. In the 10-in. neck of the weighing tank an overflow pipe led to drain. As the tank was filled to this overflow, and allowed to drain from that point, the amount of water contained in the tank was identical for each filling. The tank was filled and then the water drawn off into a barrel placed on the test scales and thus weighed. This was repeated several times, and the readings gave only from .5 lb. to 1 lb. difference in 3676 lbs. for a full tank. The boiler feed pumps drew direct from the storage tank above mentioned.

It will be noted that the temperature of the feed was

VOLTMETER RECORD, MAR. 10, 1899

much lower than in practice because of the drawing from the tank, and not from the heater. The tables give the value of the difference.

BOILER TEST

1.	Date of trial	Feb. 12,'98.	Feb. 14,'98.
2.	Duration of trial	20.63 hrs.	20 hrs.

DIMENSIONS AND PROPORTIONS

	EFFICIENCY		
45.	Efficiency of boiler—heat absorbed by the boiler per pound combustible, divided by the heat value of 1 lb. combustible	74.05	78.89
46.	Efficiency of boiler and grate; heat absorbed by boiler per pound dry coal fired, divided by the heat value of 1 lb. dry coal	59.78	67.02

NOTES RELATIVE TO TABLES.

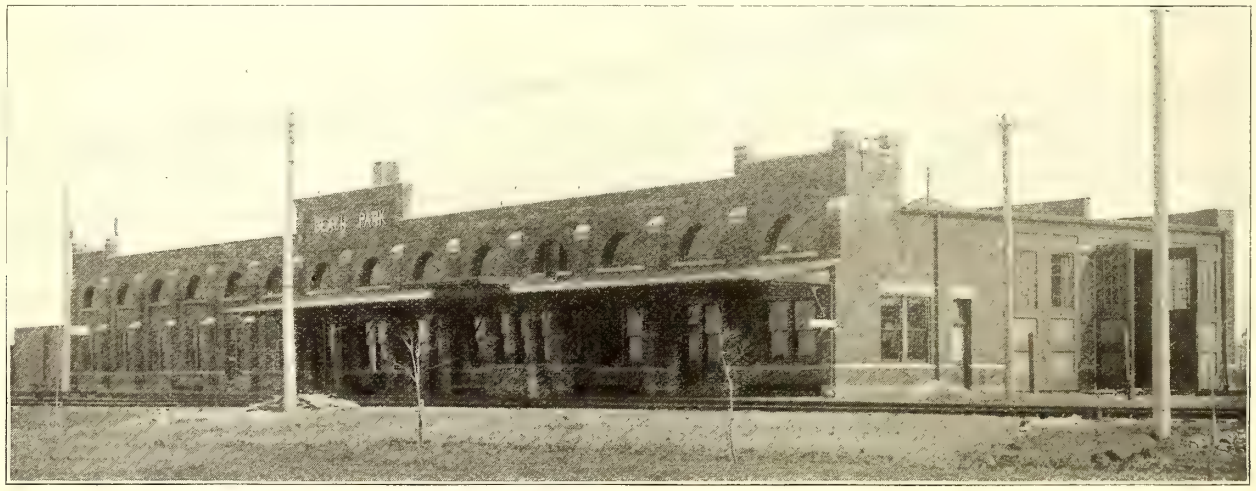
Boiler Notes

Nos. 3 and 4.—In item No. 3 the actual area of the grate is used, but the makers of the furnace rated the grate surface in projected, or horizontal area, and the item No. 4 is given accordingly.

No. 5.—Three thousand and thirty-eight sq. ft. per boiler, or at a rating of 10 sq. ft., gives 303.8 h.p.

No. 11.—Although the force of draft is given as only .2 ins. of water as the average used, a draft of from 1.2 ins. to 1.3 ins. was at all times available by the opening of the damper, and is shown on the charts of the Bristol recording draft gage as a straight, or nearly straight line, reaching out to those values at intervals. This was done by changing the valves for the draft connection to the gage from between the boilers and damper to the outside of the damper. Several times during the second test the values for the boiler draft were as high as from .6 ins. to .7 ins. (See Recording Gage Charts.) Later Note.—Results in practice often show a utilization of 1 in. for short times.

No. 14.—Temperature of every tank of water was taken, and temperature in feed pipe to boilers.



No. 21.—A considerable quantity of fine coal passed through the grates, and as it was inconvenient to return same to the furnace, it was put aside. This fine coal is ordinarily returned to the furnace, and thus is not lost in the ash. For these tests this waste amounted to 8.73 per cent the first day, and 3.43 per cent the second day. When the boilers are working up to their capacity, very little coal passes through.

No. 26.—The heat units per pound is given as the same for both days. The coal used had been in the bunkers for some time, and as the amount used for two days made very little difference in the size of the pile, it was assumed that the average of the samples for both days would give a fairer average than keeping the readings separate.

Formula used for heat value—14,600 C. + 62,000 $\left(H - \frac{O}{8}\right)$

No. 29.—Three calorimeters were used, but two of these were found to be unreliable, and so only the third, which was used on the engine in the second day's test, was used for data. This gave the amount of moisture in the steam after passing the separator, and the drip from the Holly system accounted for the rest of the entrained and condensed water in the steam system. From this total an allowance was deducted for condensation in the pipes, and the rest charged to entrained moisture in the steam from the boilers. This agreed quite well with the determinations by the above-mentioned calorimeter of the amount of moisture at the boilers on the first day's test.

	Power Factor	Lbs. water per kw.-hr.	Lbs water per i.h.p. hr.
Test of Feb. 12, 1898.....	30.8	41.34	31.01
Maximum output for one day up to July 24, 1898, gives 5 lbs. coal per kw.-hr; this, with evaporation of 7.71, gives	47.2	38.55	28.91

This test of Feb. 12, 1898, gives the same results as the average for the same output during operation from Jan. 1 to July 24, 1898. See point No. 6 on curve, which shows the test of Feb. 12 reduced to feed at 210 deg., which is the ordinary temperature of the feed water.

Engine Test Notes

During the run on Feb. 12, Engine No. 1 furnished current for the road until 10.05 A. M., when the load was changed onto Engine No. 2, which finished the run. On Feb. 14 No. 1 ran the road, and No. 2 was used on the water rheostat.

No. 13.—The large amount of leak from Holly system the first day was caused by a defective valve allowing steam to blow through. This was fixed for the second day's run, and shows only the natural leakage due to condensed water from the piping system and separators.

Nos. 15, 16 and 17.—It was inconvenient to change the piping so as to get the actual steam consumption of the pumps, and it was decided to estimate this. The number of strokes of each pump were taken, and also the average steam pressure in the cylinders, and the head against which they were working, and the steam consumption estimated.

No. 18.—This is deducted because the service pump is not a station auxiliary, but furnishes water for use outside of the station.

No. 23.—The engine set running the road (No. 1) on the second day had slightly less kw. output than on the first. If the steam be taken at the same rate per kw. it would be incorrect, as at the lighter load the set is less efficient. The amount deducted was the *difference* in kw. for the two days multiplied by 50 per cent of the *rate* for the first day.

No. 24.—Obtained by subtracting (23) from the second item in (22).

No. 28.—Obtained from average of indicator cards.

Nos. 29, 30 and 31.—Copied from boiler test.

No. 32.—Average of twenty-nine indicator cards.

Nos. 33 and 34.—Obtained from indicator cards taken at time of maximum and minimum loads.

No. 35.—Average of five sets of cards.

No. 36.—Computed from switchboard readings.

No. 37.—From items 24 and 32.

Nos. 38 to 42.—Are figured from the engine consumption alone, and do not include pumps, etc., and are, therefore, lower than the amount which would be required to run the station under this load.

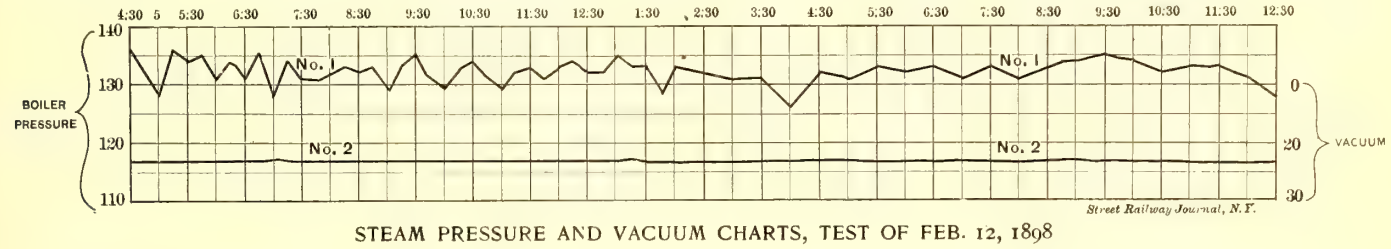
Nos. 43 to 47.—Columns Nos. 1 and 2 are figured from the total coal, and total kw. output for the two days, and include that due to the auxiliaries, while Column No. 3 is figured for the engine alone.

No. 48.—From items Nos. 32 and 35

Nos. 49 and 50.—From items Nos. 32 and 36 the item No. 50 is found, and dividing No. 50 by No. 48 gives No. 49, or, dividing the combined efficiency by the efficiency of the engine, gives efficiency of generator. These efficiencies would have beeen increased if the load had been more nearly full rated load.

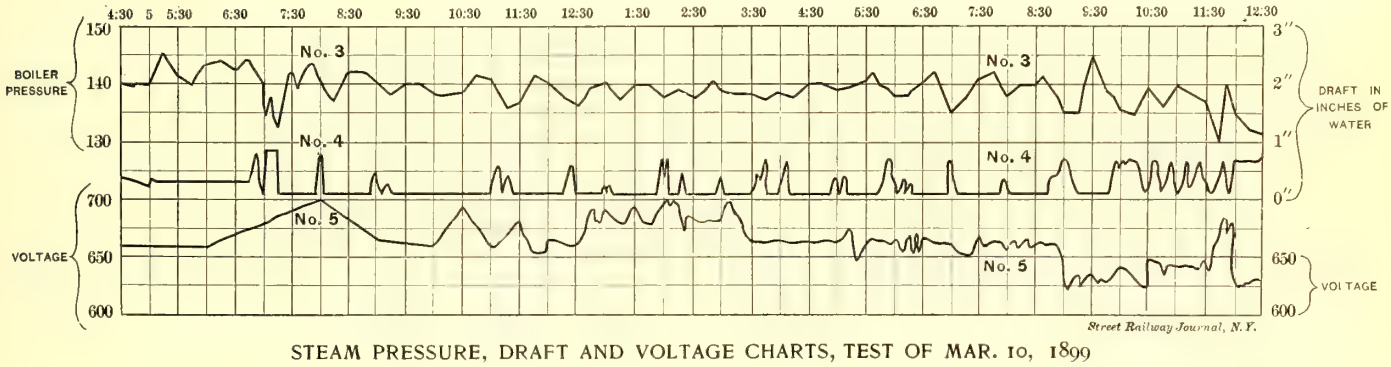
DISCUSSION OF RESULTS OF TESTS

Owing to the exceedingly variable load, the kw. per pound of coal for the run on the road was very different from what it was for the test on approximately full load, and this was to be expected.



1. The boiler efficiency was not as high.
2. The percentage of steam used by the pump was much greater.
3. The engine efficiency was very much less.
4. The generator efficiency was very much less.

The record shows what the engine only would do if fully loaded, but this can never be obtained, as the pumps and the condenser must always be used.



An approximate, but fairly close, estimate indicates that the plant at full load, and the same efficiency of boiler as at the time of approximately full load test, and the same fuel, would consume about 3.32 lbs. coal per kw.-hour; the combined efficiency of engine and generator being increased about 4 per cent. The boiler efficiency would be slightly higher, but probably 3.3 lbs. per kw.-hour is about the limit, a point unattainable, but valuable to know, for the sake of comparison of results obtained with what may possibly be considered, for this case, the theoretical limit.

Comparisons of daily output and coal consumption show the benefit of increased load on the station efficiency, and later, when more records have been obtained it was possible to plot a curve to obtain the average results, and to show how they compare with the theoretical point above mentioned.

It should be noted that the figure 3.3 lbs. per kw.-hour includes the auxiliaries which were taken for the estimate as using 14.5 per cent of the total steam. This would leave for the engine only 2.82 lbs. per kw.-hour, which, with a combined efficiency of 87.3 per cent, would give 1.83 lbs.

STEAM PRESSURE AND VACUUM CHARTS, TEST OF FEB. 12, 1898

STEAM PRESSURE, DRAFT AND VOLTAGE CHARTS, TEST OF MAR. 10, 1899

per i.h.p., and almost 2 per cent less for every 10 per cent error against the auxiliaries in the estimate of the steam used by the latter.

The success attending the operation of the road has been exceptional, and the officers whose capable management has secured this result are as follows:

B. Mahler, president, who gives the road his constant supervision; J. B. Hanna, vice-president; E. W. Moore, treasurer; J. C. Hoge, secretary; F. W. Coen, assistant secretary; W. E. Davis, superintendent.

The chief engineer of the power house is W. B. Stewart, who takes great pride in the appearance of the power house and gives it the most careful and intelligent attention. When the writer complimented the superintendent he was answered by the quotation that "it was the man behind the gun." Mr. Davis also stated that on the day previous to this statement, and also during the week of exceptionally cold weather, that the generator circuit breaker frequently operated at 1100 amps., and that 1000 amps. was carried for several minutes at a time.

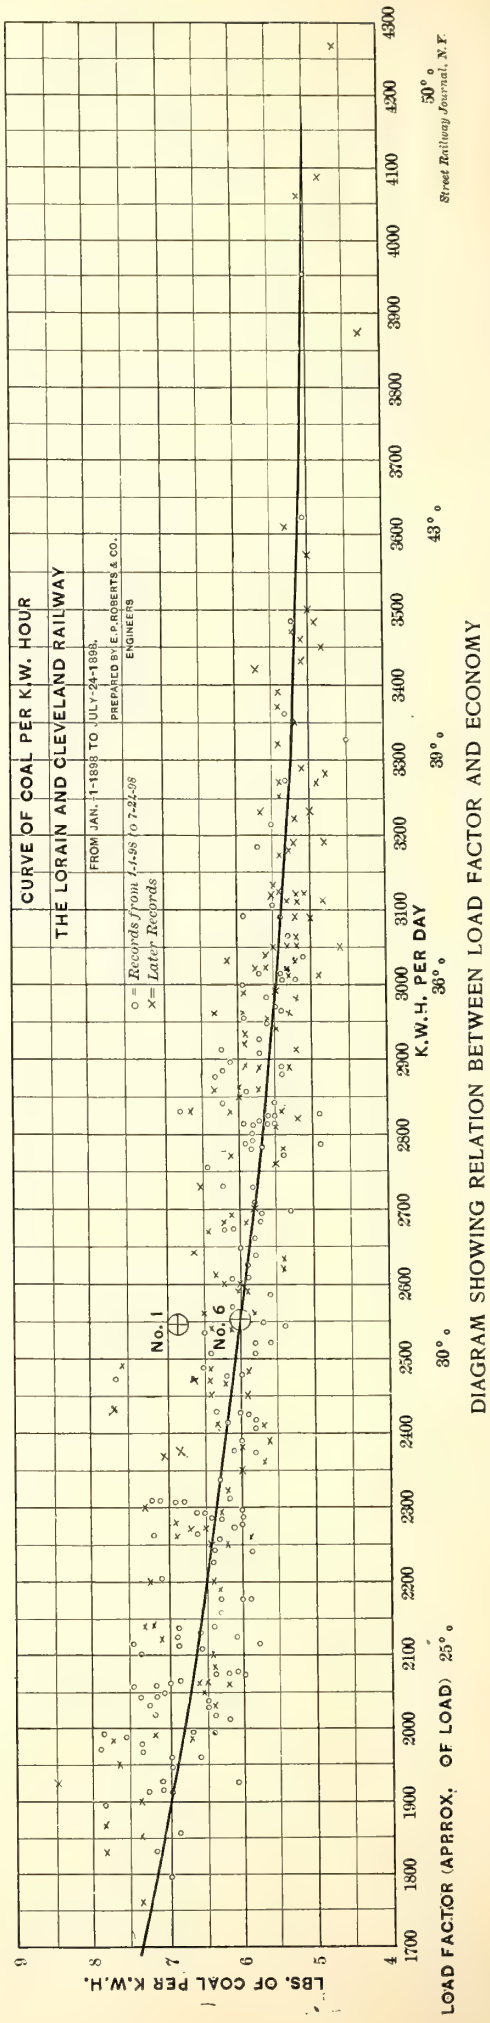
It should be noted that 1100 amps. is 100 per cent overload.

THE RELATION OF THE LOAD FACTOR TO ECONOMY

The tests given above were made to determine the exact economy of the station under conditions as they existed upon two particular days, but the company has also maintained a continuous system of keeping records showing the relation between the coal consumption and kw.-hour output on different days. The coal is weighed, as stated, as it is fed into the hoppers, and the kw. hours taken from the wattmeter on the switchboard. The form in which these records are kept is given below, showing, as will be seen, the coal per kw. hour and per h.p. hour. The records for every twenty-four hours from Jan. 1, 1898, to July 24, 1898, were then plotted on a diagram, as shown on this page by O's. Later records are shown by X's. From the O records a mean line was drawn as giving the average consumption of coal per kw. hour with different load factors. This line is also a fair mean of the X points, as will be seen from its inspection, unless possibly that the line should dip a little more for large loads. To secure uniformity in records, all points are reduced to feed water at 210 deg. F. Point No. 1 was that determined by the test on Feb. 12, 1898, with a variable load, as given above. Point No. 6 is the same record, but with feed water reduced to 210 deg., and as will be seen, it lies directly on the average line. The following points, determined by a test on Feb. 15, 1898, were not put on the diagram owing to lack of room.

No. of Tests.	Character of Load.	Kw. H.	Feed Water 39 degs. F., lbs. per kw. h.	Feed Water reduced to 210 degs. F., l bs per kw. h.
1.	Combined variable and steady..	451.2	4.39	3.74
2.	Steady (engine load only).....	451.2	3.37	2.72
3.	Limit for full load (engines and pumps) calculated as stated under discussion of results..	.....	.....	3.32

It will be noted from the chart that the best result yet obtained is 50 per cent in excess of that which would be obtained at full load. The poorest (from the curve) is 120 per cent, and the average about 81 per cent. The variation in records for the same output is due, first, to the different amounts of coal in the hoppers and furnaces at the start and finish on different days; second, to the difference caused by the starting up of new boilers; third, to the difference in the character and combustion value of the coal; fourth, to the difference in the character of the load, and fifth, to the fact as to whether the service pump was used or not.



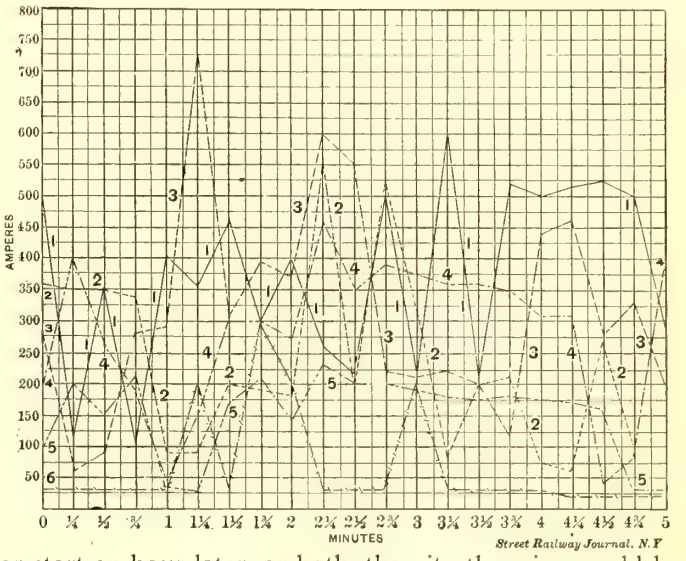


DIAGRAM SHOWING RELATION BETWEEN LOAD FACTOR AND ECONOMY

ECONOMY POSSIBLE FROM STORAGE BATTERIES

The results shown by the above curve will be found of interest to those considering the application of storage batteries to interurban roads. As is well known, the usual practice is to install a battery of sufficient size to take care of the overloads, the battery being charged at the time of underloads, and consequently the engine and generator running at all times at approximately rated load, with the result that the fuel consumption per i.h.p. and per kw. hour is greatly lessened.

One of the advantages derived from a chart and tests of this kind is the ability to determine the possible economy from the use of storage batteries as station regulators. When a plant is originally designed for the use of storage batteries, the steam end should be proportioned differently from when it is designed for exceedingly variable loads without the use of a battery. If the plant in either case were to be compound condensing, the ratio of the cylinders would be much greater for a storage battery plant than for one with variable load, and if batteries were not to be used and the decision were against compounding and condensing, the use of a battery might so modify the conditions as to make compounding and condensing advisable. In a similar way it might make advisable the use of economizers and induced draft in cases where otherwise it would not be advisable, or, at least, would be very questionable. A careful designer will also change the ratio of heating surface to grate surface and possibly the amount of each provided. If, however, the plant is one which is already in operation, as in the case of the Lorain & Cleveland Railway, the question of advisability of installing a battery auxiliary to take care of fluctuations under the present operating conditions, or to allow additional output without adding engines, boilers and generator, it would be considered along the following lines:

For the output now required for both the summer and winter traffic the curve shows the average coal per kw. hour, and the test indicates what result would be obtained if the load were constant. The percentage of saving of fuel would be as indicated by the figures given under "Discussion of Results of Tests," above. Whether such a saving would make it advisable to install a battery depends upon the price of coal, the amount used, the cost of the necessary battery, and the interest and depreciation charges which it is considered proper to allow, also whether any financial value shall be given to providing power which could be used for a short time in case of total break down. As a matter of fact, the importance of the latter consideration in a first-class modern station is small, but a practical economy is often secured by the use of a battery in allowing the station to shut down an hour earlier or start an hour later, or both, than it otherwise would by taking care of the first car out over the line, and the last car in.

It is by obtaining such data as above that exact designing can be accomplished, and both the Lorain & Cleveland Company, as represented by its officers, and engineers have shown a commendable spirit in allowing its publication.

SAMPLE WEEKLY STATION ORDER

Quickly Baked Coils

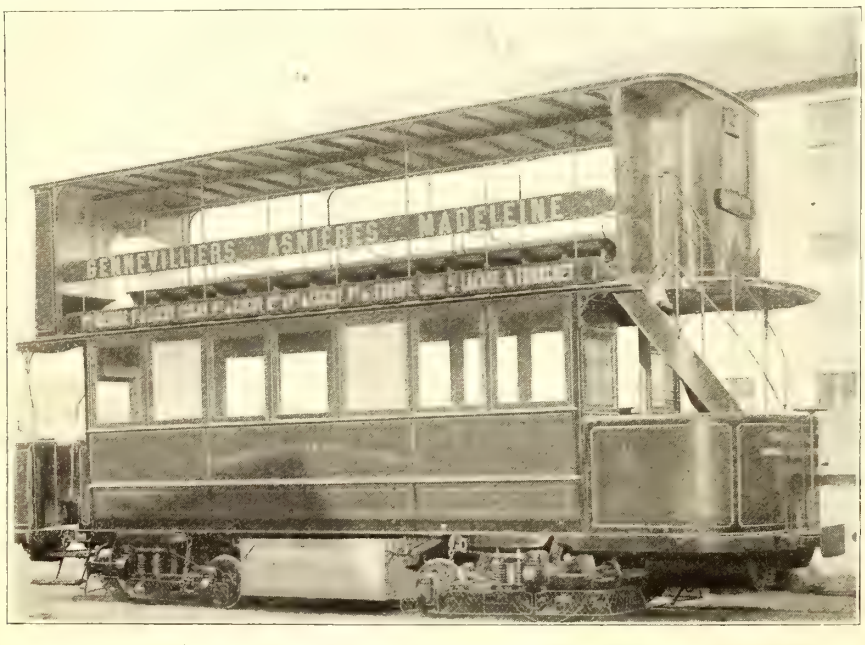
BY J. F. HOBART

In cases where small coils are required for immediate use and there is no time in which to bake the shellac sufficient to hold them in place, they are made ready for instant duty by a method called "burning out" in the very few shops where I have ever seen the method used. Supposing the coil is a four-wire concern to form a part of the winding of an armature. It is wound into shape and held by several small metal clips so that it can be removed from the form on which it is wound and then immediately saturated with thick shellac varnish.

When possible, and that is in most cases, the shellac is applied before the coil is removed from the form, but in either case, after being shellacked, the coil is placed in the heat of a gasoline torch or Bunsen burner, and the shellac heated to the igniting point. It will blaze fiercely, and at just the right time—decided by experience—the blazing coil is removed from the flame and the blaze extinguished. The shellac must not be burned—that would spoil it for the purpose, but just enough of the alcohol is removed to make the shellac hard, but not brittle. A very little practice will determine just when to stop the firing operation, and a good coil can be quickly made ready for use by this process.

Under the average conditions a 22-ft. closed car or an eight reversible seat open car should be the limit for a single truck. Although there are single trucks which will carry a longer body fairly well, yet the increase in maintenance will, in most cases, warrant the use of double trucks. From paper at the Boston Convention, 1898.

Electric Railways in Paris, France



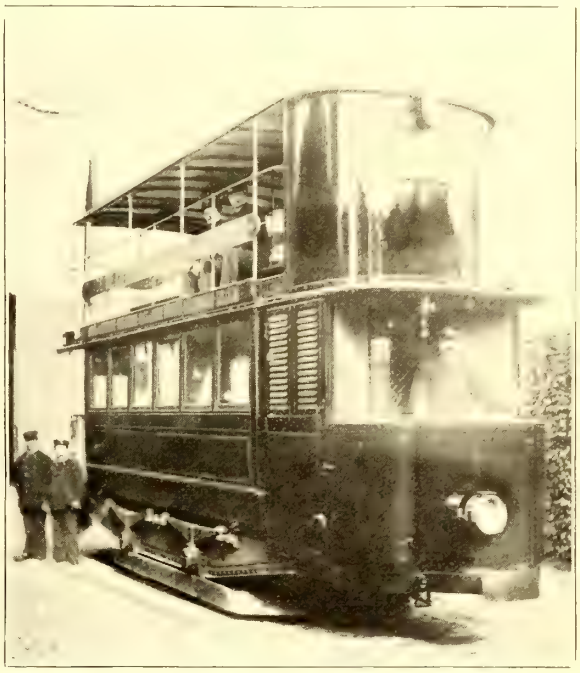
There are three companies which operate electric railways in the city of Paris—the Compagnie des Tramways de Paris et du Département de la Seine, the Compagnie Générale Parisienne de Tramways and the Compagnie du Tramway de Paris à Romainville. The principal line leaves from in front of the Madeleine, in the center of Paris. The power station is situated on the line of the road at Asniéres, and contains three engines, each connected to a Walker 200-kw. generator. Two types of cars are used, a single and double truck, both of which are illustrated herewith. The double-truck car, which is mounted on Brill maximum traction trucks, carries fifty-eight passengers, and weighs, complete, 17,000 kg., made up as follows: weight of car body, 4200 kg.; trucks and motors, 4700 kg.; battery, 3700 kg.; fifty-eight passengers and two employees, 440 kg. A full description of the car, which operates on the mixed trolley and accumulator system, was published in the Street Railway Journal (international edition) for July, 1898.

The Compagnie du Tramway de Paris à Romainville operates cars from the Place de la Republique, at the center of Paris, to the Port de Romainville, and thence to Coté de Noisy-le-Sec. The line was installed in 1896, is equipped with Claret-Vuilleumier surface contact system. The length in Paris is 4 km. of double track, and outside of Paris 3 km. of single track. The minimum curve radius is 25 meters, and the steepest grade is 5½ per cent. The power station is situated at Lilas, about two-thirds of the distance from the Paris terminal. It contains three boilers, four Corliss engines, four generators, and adjoining it is a car house for thirty cars. The cars are capable of carrying fifty-two passengers. They weigh 13,000 kg. loaded, and are operated by two 30-h.p. Walker motors.

The Compagnie Générale Parisienne de Tramways has a line 6.2 km. in length, part of which is operated by the trolley system and part by the underground conduit. There are seventeen motor cars, each equipped with two General Electric motors. The power station contains three Thomson-Houston 200-kw. generators.

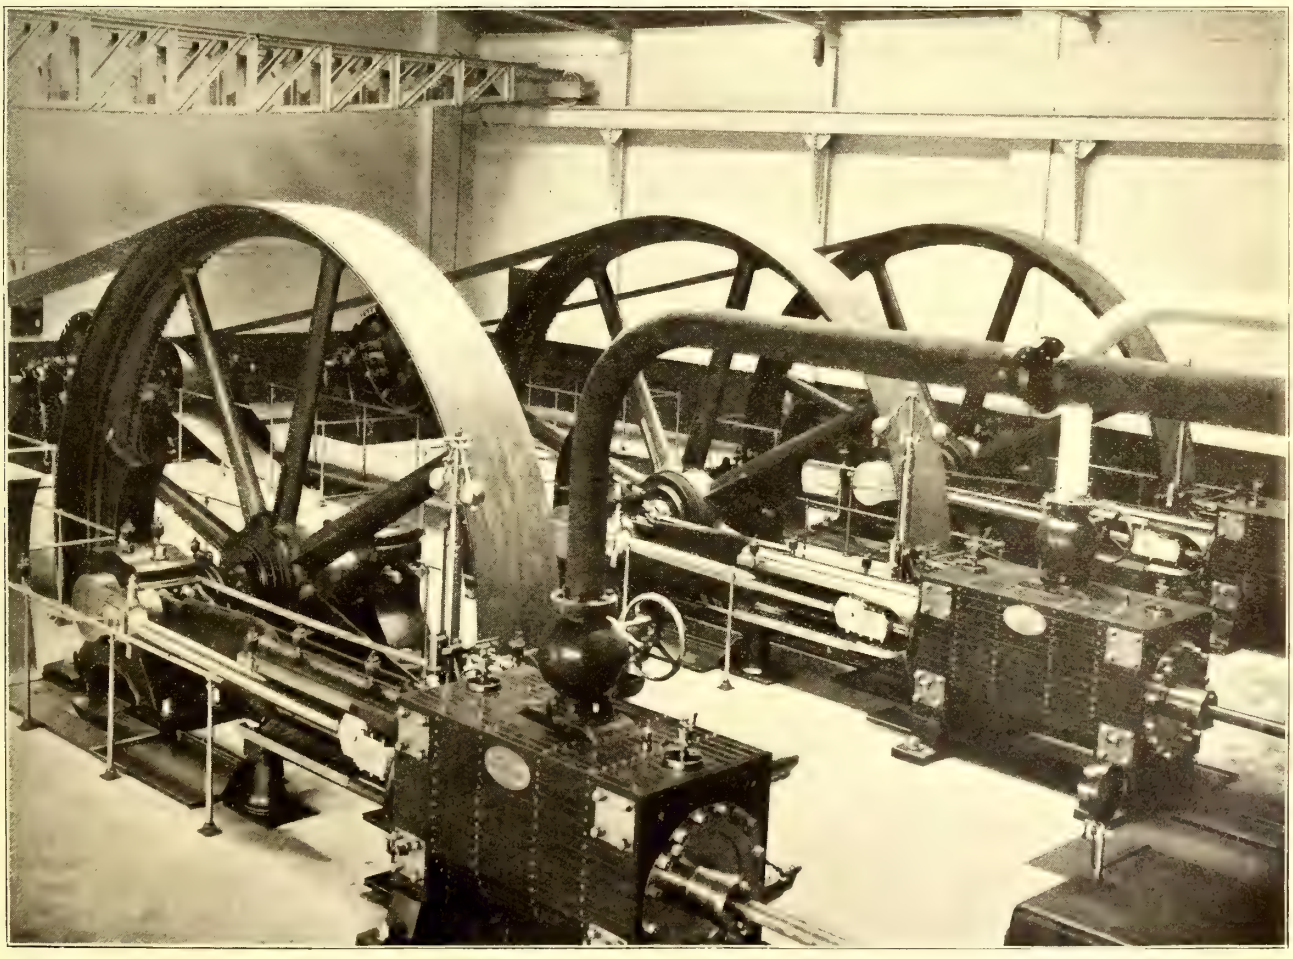
ELECTRIC TRAIN, RAINCY-MONTFERMIEL RAILWAY

DOUBLE DECK STORAGE BATTERY CAR, PARIS



ELECTRIC TRAIN, RAINCY

The Compagnie du Tramway Raincy à Montfermiel, while not in Paris, is not far from it, and it is proposed to extend the road into the city, by way of Romainville. It extends from Romainville to Montfermiel, has a length of 7 km., and is equipped with the trolley system. There are ten motor cars, weighing 12,500 kg. each, equipped with two 25-h.p. Walker motors.



The following summary of the tramway companies in Paris is taken from "Revue des Transports Parisiens." There are nine companies, operating as follows:

1. Compagnie Générale des Omnibus. On Jan. 1 this company had 184.7 km. of track laid with Marsillon rail, 9.3 km. laid with Broca rail, 15 km. laid with Vignole or T rail, and 23.3 km. laid with "American" or strap rail. The company has fourteen Rowan (steam) cars, fifty-four Mekarski (compressed air) cars, fifty-nine Serpollet (steam) cars. The company had 4800 horses on July 1, 1898.

2. Compagnie des Tramways de Paris et du Department de la Seine. This company has 79.9 km. of track laid with Broca rail and 29.7 km. of track laid with Vignole rail, all operated by mechanical power, viz.: Lamm Francq (fireless) locomotives, Serpollet (steam) locomotives, accumulator cars, and, for a short distance in the outskirts of the city, a trolley line. The company has twenty Lamm Francq locomotives, twenty-two Serpollet motor cars, which are being replaced with accumulator cars, fifty-five accumulator motor cars, twenty-eight motor cars for a mixed trolley and accumulator service, and five trolley cars.

CAR ON SURFACE CONTACT SYSTEM, PARIS—ROMAINVILLE

ELECTRIC POWER STATION AT ASNIERES

3. Tramway à Vapeur de Paris à Saint-Germain. This company has seventeen 17-ton steam dummies.

4. Funiculaire de Belleville, the Belleville Cable Railway. This road is 2 km. in length, laid with Broca rails, and has twenty-one cars.

5. Compagnie Générale Parisienne de Tramways. This company has 111.9 km. of track, of which 60.9 km. is laid with Broca rails, 32.4 km. with strap rails, 9.8 km. with Marsillon rails, and 8.8 km. with Vignole rails. This company has 154 cars, all horse cars with the exception of a

short electric line, most of which is trolley, but a short portion is underground conduit.

6. Compagnie du Chemin de Fer de Paris-Arpajon. This company has five compressed air locomotives and

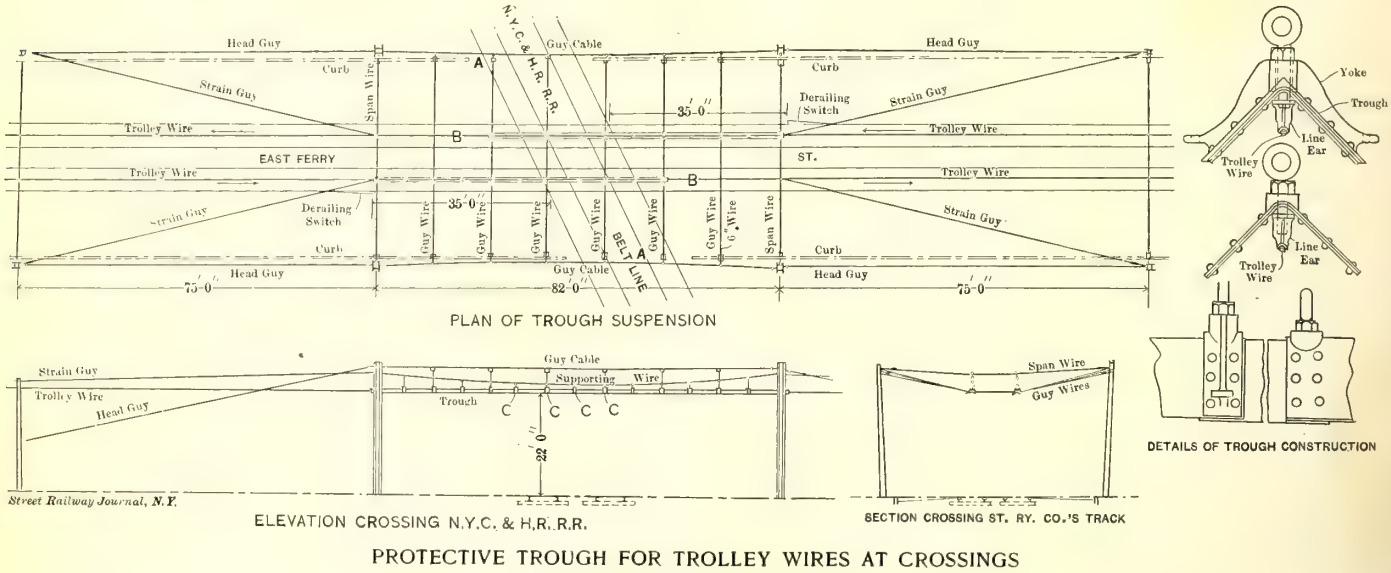
STORAGE BATTERY CAR, PARIS

twenty-one steam locomotives, but is proposing to install an electric system on part of its line. The track is laid with Broca, Marsillon and Vignole rails.

7. Compagnie des Chemins de Fer Nogentais. This company has 17.3 km. of track and owns nineteen compressed air motor cars and ten trail cars.

8. Compagnie des Tramways de Saint-Maur. This company has 12 km., and owns ten compressed air motor cars and eight trail cars. The line will be equipped with the trolley system soon.

9. Compagnie du Tramway de Paris à Romainville. This company has about 7 km. of track, and operates twenty electric motor cars on the Claret-Vuilleumier surface contact system.



In addition an electric line will be started during the year by the North and South Tramway companies. The trolley system will be used outside of Paris, and the conduit system within the city limits.

Trolley Trough for Steam Railroad Crossing

The accompanying engraving shows a protective device for the trolley wire of electric railways at steam railroad crossings to avoid the possible danger of the electric car becoming stalled on the steam railroad track by either a break in the trolley wire or the trolley jumping off the wire at a critical time. The device was suggested by the engineer of the New York State Railway Commissioners and has been adopted by the Buffalo Railway Company at fourteen points where its tracks cross steam railroad tracks on grade. The accompanying drawing, for which the STREET RAILWAY JOURNAL is indebted to Robert Dunning, master mechanic of the Buffalo Railway Company, shows the construction of the device, as well as the method of supporting it.

The trough is constructed of two sheets of hard drawn brass in sections 8 ft. long, riveted together with copper rivets, and attached to heavy yokes, shown in the detail drawings at the right. The trough is not insulated from the trolley wire, but in metallic contact with it. One end of the span wire is attached to the ends of the yokes, and the other end to heavy box-plate poles, which are 33 ft. long, and set 7 ft. in the ground so as to maintain a height of 22 ft. A two-track crossing, such as that shown in the engraving, requires eight poles of this character, four used in supporting the trough, and the other four for the head guys.

The guy cables, shown by *AA* in the plan, are made up of two $\frac{3}{8}$-in. steel cables twisted together, and from these, smaller cables are run to the trough to prevent its swaying. These smaller cables are shown by *CC*, and are insulated from the supporting guys and from the trough. This method of suspension permits the adjustment of the level of the trough to any desired height.

PLAN OF TROUGH SUSPENSION

DETAILS OF TROUGH CONSTRUCTION

ELEVATION CROSSING N.Y.C. & H.R.R.R.

SECTION CROSSING ST. RY. CO.'S TRACK

PROTECTIVE TROUGH FOR TROLLEY WIRES AT CROSSINGS

The angle of some of the tracks of the Buffalo Railway protected in this way is such that a curve on each side of the crossing is necessary, but the engineers have been able to protect the crossings without much trouble. They consider the device a good one, as it is practically impossible for the trolley wire to break, there being no strain upon it, but if it should part, the inverted trough will catch the trolley wheel and afford a metallic circuit to carry the car over the crossing.

The Boston Elevated Railway Company is planning to install a large power station at Lincoln Wharf. It will contain six 3000-kw. units.

Overhead Line Construction I.

BY ALBERT B. HERRICK

The overhead line is one of the most important parts of the equipment of an electric railway, and one in which good construction counts for as much in percentage of first cost as in any other part of the installation. I feel, therefore, that a practical exposition of some of the main principles relating to the erection and selection of apparatus and methods of construction will be of interest to co-workers in the railway field. Taking up the line, the question of poles and of which is the most economical pole line to erect immediately rises. This is largely a matter of local figuring, for in the case of suburban towns wooden poles may often be obtained at such a low price that the line can be renewed once, or perhaps twice, during the life of an iron pole at approximately the same cost.

In a trolley line, where continuity of service depends on the stability of the structure carrying the conductors, the whole overhead construction and trolley wire alignment is dependent upon the rigidity and stability of the poles. Care should be taken, therefore, when deciding between wooden and iron pole construction, to consider not only first cost, but also local climatic conditions, which sometimes seriously affect the life of wooden poles, but which usually have no effect on well-painted steel poles. For instance, the soil in the streets of a large city is usually charged with gas and ammonia, a condition which induces premature rot in wood.

The life of iron poles can be assumed as thirty-three years, provided the poles be painted with a good anti-rust paint every six years, and on this assumption there is an annual depreciation of 3 per cent in an iron pole line. Considering now the life of wooden poles, it should be remembered that there are a number of places in wood where rot starts besides in that part which is buried. Every bolt and nail entering or piercing the wood opens up a place where moisture can enter and rot begin. An average of eleven years' life for *city* and suburban construction is a fair assumption, which gives a depreciation of 9 per cent per year. The investment, based on these figures, presents the following comparison between iron and wooden poles where used for trolley line construction, and shows the profit in using the best material:

With an iron trolley pole, set so as to bear a strain of 600 lbs. at 22 ft. above the ground, and buried 6 ft. 2 ins. in concrete setting, the cost per mile will be as follows: Poles, set 100 ft. apart, 104 poles, at $17.50, will equal $1,820; digging and setting in concrete, at $4.30, will equal $447.20; painting poles, at 30 cents, will give $31.20. The poles should be painted once each six years, which will cost $31.20, making five paintings at $31.20, or a total of $156. The total construction and maintenance per mile will cost $2,454.40, which when divided by the life of thirty-three years, will give a depreciation of $74.37 per annum.

Wooden poles of hard pine, planed and chamfered, will show the following necessary expenditures: One hundred and four poles per mile, to fill the same specifications regarding height as the steel poles—104 poles, at $6.30, will equal $655.20; labor erecting and digging, at $2.65, will equal $275.60; painting poles, at 40 cents, will give $41.60; making a total of $972.40. At the end of six years the painting must be done again at a cost of $41.60, and at the end of eleven years there will be an expenditure for a new pole line, or $972.40. Adding the expense of re-aligning span wires, $240 per mile, will give a total expenditure at the end of thirty-three years of $3,522, and with a depreciation per year of $106.73.

The comparison now stands: Total cost of steel poles for thirty-three years, $2,454.40, and for wooden poles, $3,522. This gives a difference in favor of the steel poles of $1,067.60 per mile. The depreciation rate of $74.37 for steel poles and $106.73 for the wooden poles gives a difference of $32.36 per annum per mile. If interest was charged against the invested amounts for the term of life of property, it would reduce somewhat the showing in favor of the steel pole, but in any method of figuring the relative values from an investment standpoint the showing is greatly in favor of the iron pole line. From an engineer's standpoint the superiority of the iron pole presents many advantages besides the lasting qualities, which directly affect the operation of the road. The item of re-

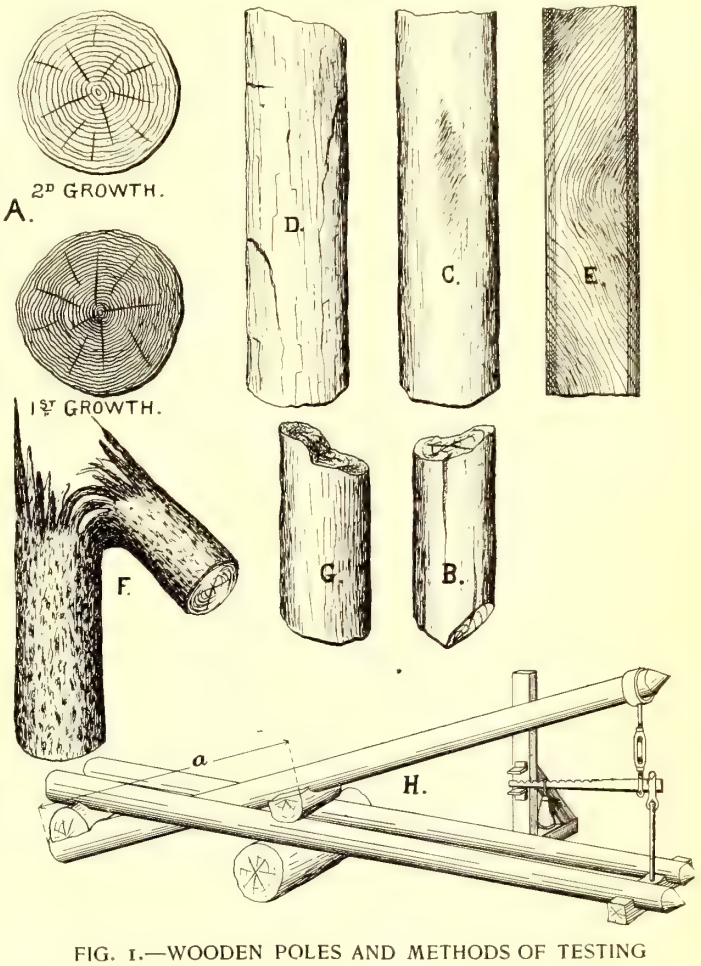


FIG. 1.—WOODEN POLES AND METHODS OF TESTING

equipping and renewing, which involves the adjustment of span wires and trolley wires, is directly contingent on the removal of poles, and should properly be charged against the wooden pole line, since it is obviated by the use of iron poles. The expense of keeping a trolley line taut and in good alignment, which insures the trolley keeping contact with the trolley wire, is largely dependent upon the rigidity of the pole line, and it is well known that eight years ago iron poles were manufactured in order to gain these results.

As previously stated, however, certain local conditions may be favorable to the use of wooden poles, and the essential features of a good wooden pole line will now be considered.

WHAT CONSTITUTES A GOOD WOODEN POLE LINE

Wooden poles are divided into classes dependent on their form, growth and symmetry. The woods usually chosen are chestnut, hard pine and cedar. As a rule, the

dimensions of round wooden poles should bear the relations in the table on page 279. Cedar poles over 47 ft. long should not be used, as the wind and conductor strains are liable to break them down. All first-class chestnut poles should be second growth—that is, a pole grown from an offshoot of a chestnut tree that has been cut down. This can be determined by the annual rings being larger and of a lighter color, as shown at *A* in Fig. 1, or by the knot holes being nearer the top of the pole. If the bark is on the pole the serrations should not be deep in second growth chestnut.

A pole should be fairly round, and not vary more than 10 per cent from true diameter in all around dimensions.

In order that the pole line have a neat appearance, the poles must be straight; no deflection greater than 4 per cent should be allowed from the center line. A pole

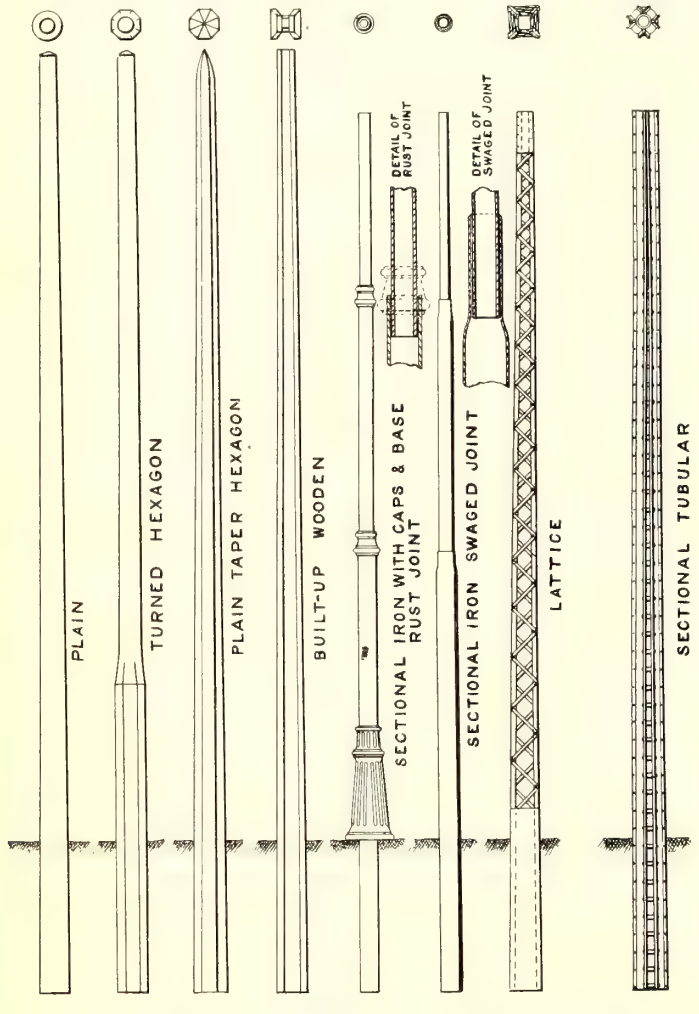

FIG. 2.—SHAPES OF STANDARD AND SPECIAL POLES

should be cut down when the sap is not running, either in midwinter or summer, in order to give the best life, as the sap contains the elements that decompose and start dry and wet rot.

After the pole is cut it should be allowed to stand with the bark on it, if exposed to the sun and weather, to season; otherwise it will be sun-checked—that is, cracks running parallel to the trunk shown at *B*, and exposing the interior of the pole to rot. A wind-shaken pole, shown at *D*, is one which has been subjected to severe wind storms during growth, and which has fractured the fibres and permanently weakened the pole.

Heart rot in second growth chestnut is generally near or at the butt. If a pole is affected by rot where it is exposed after peeling, internal rot will show on the surface of the pole by dark spots over the affected parts; when exposed for any length of time fungi will grow on the outside of the pole over the rotten portions. Knot holes larger than $\frac{3}{4}$ in. within 10 ft. of the butt greatly decrease the strength of the pole, for at this point the greatest strain comes. Knot holes where the core has dropped out or is loose indicate premature decay in poles. These points are given to indicate what to look for in the selection of first-class poles.

Chestnut deteriorates rapidly when the surface sap wood is cut, and for this reason hard pine is usually used where special shapes, such as hexagon, octagon, beveled or turned poles, are required. These are not, as a rule, made longer than 40 ft. In the selection of sawed poles the heart should be central to the axis of the pole. Wavy grain lines, as at *E*, on a sawed pole indicate it was gotten out of a crooked log, and heavy side strains are very liable to fracture such timber.

Cedar has neither the elasticity nor tensile strength of chestnut or hard pine of the same size, the fracture being a sharp one across the fibre, as shown at *G*, while chestnut still maintains its fibrous fracture when broken, as shown at *F*. Cedar, however, can be secured of very uniform sizes, and in some sections the increased size necessary to equal chestnut and hard pine in tensile strength still makes them a cheaper pole.

IRON TUBULAR POLES

Iron tubular poles are made up to 50 ft. high; both the standard pole and the extra strong poles are made to meet the variations in line strains. Taking one length most commonly used, which is 31 ft., they are usually divided into five classes:

	Lateral strain in lbs. to show 6 in. deflection. Pounds.	Pounds which will give permanent set of ½ in. Pounds.
No. 1	350	700
No. 2	500	1,000
No. 3	700	1,200
No. 4	1,000	1,700
No. 5	2,000	2,600

The test should be made when the pole is set in a proper concrete bed 6 ft. deep, and the strain applied to the top of the pole.

The poles should be as nearly round as possible; should not deviate more than $\frac{1}{8}$ in. between maximum and minimum diameter, and thickness of tube should not vary more than 1-32 in.; $\frac{1}{4}$ in. is the greatest deviation that will be allowed from true diameter at the top of the pole. As these poles are made up of sections, some provision should be made to test them where these sections are mechanically connected together. One provision inserted is that the pole should be dropped a distance of 6 ft., butt foremost, on a solid foundation, three times without the joints loosening.

There are two ways of connecting the different lengths—one is by heating the larger pipe, and, while hot, swaging the larger pipe down to the smaller cold pipe, over a length of about four times its diameter; when this joint cools the shrinkage of the outer pipe grips the inner pipe; tests of these joints usually show that they are stronger than either of the single pipes to both compression and lateral strains.

A guard ring slipped over the pole to rest on the earth at its base has been used, but water is retained here, rusting the pole at the point where it has to bear the greatest strain; and these have been removed in a number of cases and the life of the pole prolonged.

The other method is to introduce between the inner and outer pipe a rusting mixture, usually of sal ammoniac and iron filings; in oxidizing this mixture increases its volume, thus expanding and making a union between these sections. In testing this class of pipe for deflection the joints sometimes yield and show more permanent deflection than is caused by the pipe alone. These pipes are usually constructed by uniting three sections of round pipe.

The following weights and lengths are usually carried in stock:

27 ft. long, 240 to 350 lbs., standard; 335 to 560 lbs., extra strong.
28 ft. long, 250 to 610 lbs., standard; 345 to 1,175 lbs., extra strong.
30 ft. long, 270 to 780 lbs., standard; 375 to 1,380 lbs., extra strong.
35 ft. long, 800 to 1,050 lbs., standard; 890 to 1,670 lbs., extra strong.
40 ft. long, 850 to 1,530 lbs., standard; 1,335 to 2,355 lbs., extra strong.
45 ft. long, 1,174 to 1,665 lbs., standard; 1,835 to 2,600 lbs., extra strong.
50 ft. long, 1,345 to 1,800 lbs., standard; 1,995 to 2,835 lbs., extra strong.

DIMENSIONS OF ROUND WOODEN POLES.

Length in Feet of Pole.	At Butt. Cir. in Inches.	At Butt. Diameter in Inches.	At Top. Cir. in Inches.	At Top. Diameter in Inches.
30	33	10⅝	18	5¾
35	36	11½	20	6⅜
41	39	12½	23	7⅜
47	44	14	23	7⅜
52	47	15	23	7⅜
57	50	16	23	7⅜
68	53	16⅞	23	7⅜
73	56	17⅞	23	7⅜
84	64	20⅜	25	8

In the specifications for poles the above points, which are desirable, can be incorporated.

SPECIFICATIONS FOR WOODEN POLES

A selected lot of poles costs more than the run of the stock, yet in ordinary trolley line construction money can be saved by designating exactly how many of each class of pole will be required, the best and most uniform poles being for streets and highways, and the poorer qualities used along the country roads. Corner poles, and where extra span weights are to be supported, should be specially listed in the specifications; also stubs and anchors or foundation timbers. By careful attention in listing what is required for the complete pole line a saving of pole cost and time can be effected.

Specifications are varied for every class of line construction, but the usual clauses which relate to the class of pole to be delivered are as follows:

Round poles, first class.

There are to be (——) poles, (——) ft. long, with an average butt diameter of (——) ins. and an average top diameter of (——) ins., to be a gradual taper from the bottom to the top, to have no deflection bend or twist which will give the pole a greater deflection than (——) per cent from the true axis, that the pole shall be peeled clean of bark and fibre, that sun cracks shall not show on the surface of the pole, neither shall it be wind shaken or checked; no knots over (——) ins. will be passed in this class. The butt shall be sawed square and the top chamfered at an angle of 45 degs., the knots shall all be trimmed close, gains for cross arms to be cut (——) ins. from the bottom of the chamfer, and to be cut (——) ins. deep and (——) ins. wide. These poles will all be of (——) wood and show no signs of dry or wet rot.

For square sawed poles the specifications vary in this way: The pole shall be (——) ins. by (——) ins. at butt and (——) ins. by (——) ins. at the top; shall be planed and chamfered, the heart of the tree shall be central to the long side of the timber; where this pole is to be beveled on the edge the width of the bevel should be given, also where it is to begin, how far from the butt of the pole. In hexagon poles the length of the sides of the hexagon, as well as the diameter of the pole, should be given, as also the taper of the poles. In fancy turned poles the height of hexagon and beginning of turned part of poles should also be given. Built-up poles are special, and need drawings to clearly define the design. The length of a wooden pole may vary within such wide limits that sizes will have to be selected to give ample factor of safety for the line strains thrown on them, and depends on the soundness and preservation of the wood to maintain the line in service. A pole that has been thoroughly weather cured standing is stronger than a new pole which is partially green. A green pole shows greater deflection and less tensile strength than one that has been standing some time, so lumbermen do not like to be bound in a specification to the deflection and breaking strains which are applicable to iron poles, and they are not usually inserted.

SPECIFICATIONS FOR IRON POLES.

The weight and dimensions of each section and total length of pole are usually specified. The composition of the metal required may be specified, seamless steel tube now being generally used. The method of putting the sections together may be restricted in the specifications; the tensile strength, as well as the deflection and permanent deflection for different strains, are usually incorporated. To be delivered painted with (——) coats of anti-rusting paint is required both inside and out; also a turned plug of wood driven in at the butt end, and sometimes at the top, are necessary where they are to be handled much in transportation. Collars, flanges and tops are accessories in most cases on the pole. Manufacturers can drill any holes in the pole without any appreciable advance on the first cost. These holes, with their sizes, should be located and specified.

Lattice poles vary so much in the angles and spacing of the lattice, the slope and character of base, that the contractor or manufacturer should indicate what is desired or what will be furnished by a drawing. The pole can be specified regarding its mechanical strength and deflection the same as the round pole.

Fancy and special poles are not standard, and cannot be subject to general specifications, unless the product of a single manufacturer is to be adopted.

For shapes and special poles see Fig. 2.

STRENGTH OF AND METHODS OF TESTING WOODEN AND IRON POLES

The method usually given to test a pole is to set it the proper depth in the ground and apply a tackle to the top and draw it up with a given tension and note the deflection. The way it is usually applied is that the tension is usually put at an angle from the ground; the tension is partly borne by the pole and partly given to springing the pole over; the ratio of the two depends on the angle of application. Any yielding in foundation is liable to be charged to elasticity. If the pole is planted in cement, several days should

be allowed for it to set before the test, which makes the test a lengthy affair. I have found that the following will give all the practical results necessary, and can be readily constructed and calibrated on the spot. (See *H* in Fig. 1.) For this testing rig two of the largest and most symmetrical poles are selected; they are then laid by the side of each other and separated far enough apart to allow any of the poles to be tested to lie between them. They are braced together at two points, the distance *A*, from the bottom of the foot brace to the top of the head brace, to be the depth of setting to be employed in this pole. Sufficient area to these braces should be given so the strain applied will not crush the fibre of the pole under test. A 12-in. turnbuckle, a 1 to 20 steelyard, with a 100-lb. weight, completes the outfit. One arrangement can be made as above. The weight on the steelyard is fixed, and, after the bridle is put over the pole, the turnbuckle is tightened until the steelyard is balanced. When the specified tension is applied the deflection of the pole is measured by a mark on a board opposite the pole under test.

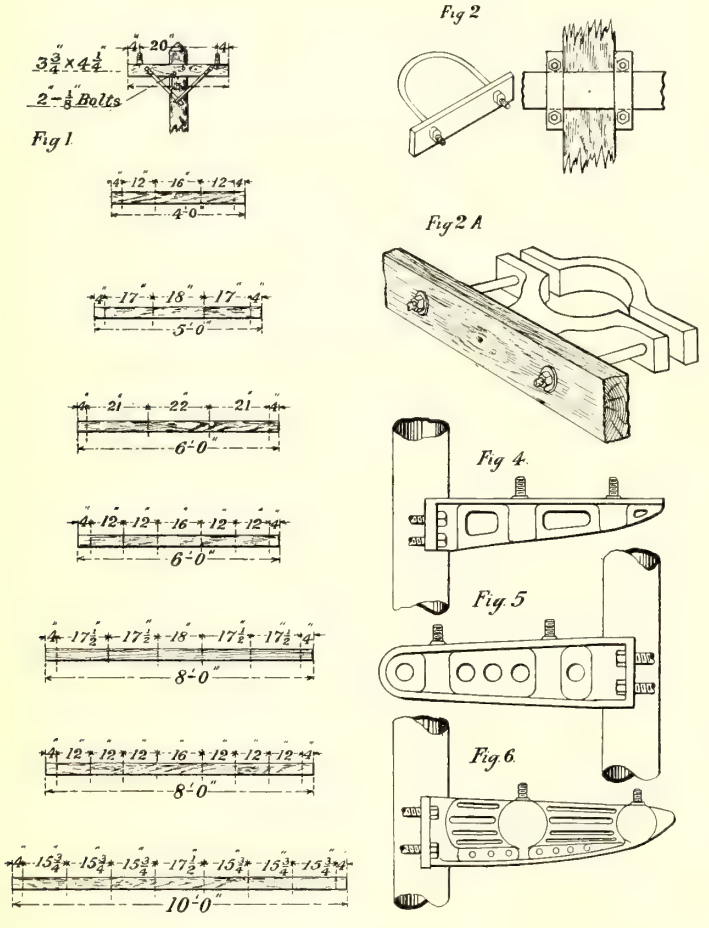

FIG. 3.—CROSS ARMS

This deflection is composed of the yield of the braces and the flexibility of the crib, but the pole on returning will show the permanent deflection, which will be the difference before and after the strain. Iron poles can be tested by the same method by substituting an iron pole for the wood, and the steelyard should be provided with a ratio of weights, so as to reach a 2000-lb. strain where extra heavy poles are to be tested.

The elasticity of wooden poles is approximately as follows where the pole is 30 ft. long and placed 6 ft. in the ground:

Round bottom.	Top.	Deflection.	Chestnut.	Cedar.
10⅝ in.	5¾ in.	7 in.	340 lbs. to 510 lbs.	360 lbs. to 406 lbs.
11½ in.	6⅜ in.	7 in.	405 lbs. to 680 lbs.	432 lbs. to 540 lbs.
12½ in.	7⅜ in.	7 in.	490 lbs. to 935 lbs.	495 lbs. to 675 lbs.

The above was the average of a number of experiments.

CROSS ARMS, SIDE ARMS AND BRACKETS

The standard cross arms usually kept in stock are given in Fig. 3, with the dimensions and spacing for pins Cross arms are usually kept in white or Norway pine or long leaf yellow pine. The tensile strength of Norway pine is approximately 10,700 lbs. to the sq. in., and the breaking cross load for long leaf yellow pine is 21,300 lbs. per sq. in. The breaking cross load for the standard size of cross arm is 5060 lbs. for white pine and 3820 lbs. for yellow pine. Records show that the long leaf pine is 40 per cent stronger, but the yellow is more durable, as it does not rot so readily where the iron bolts pierce the cross arm, which is the point at which the cross arm has to bear the greatest strain. In order to avoid piercing the wood at this point with wood poles and also where wooden cross arms are used on iron poles, straps and plates are employed, as shown in 2, Fig. 3. The pole is gained in the regular way when wooden, but where the pole is iron a saddle is cut into the cross arm to make it fit the pole and thus increase the bearing area of the cross arm. No. 2 A, Fig. 3, shows a cast-iron fitting to attach a wooden cross arm to an iron pole. For securing cross arms to poles in railroad feeder work use ⅝-in. bolts or ½-in. lag screws. The cross arms should be planed straight grained and painted with two coats of Prince's metallic paint, made up in the proportions of 7 lbs. to 1 gal. of pure linseed oil.

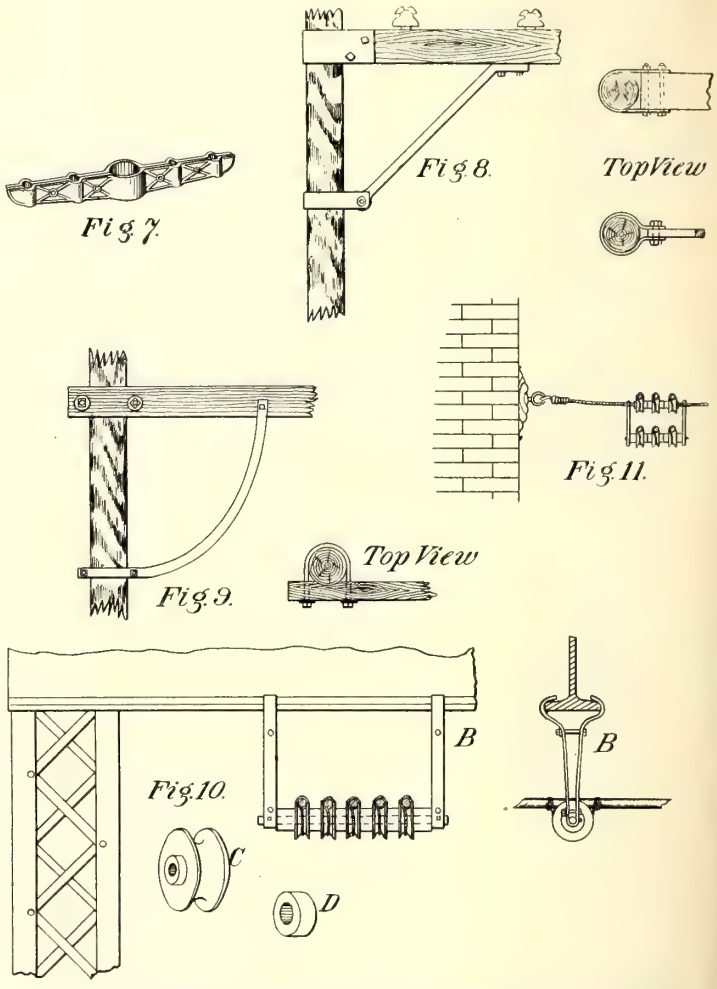

FIG. 4.—CROSS ARMS, SIDE ARMS AND SPECIAL METHODS

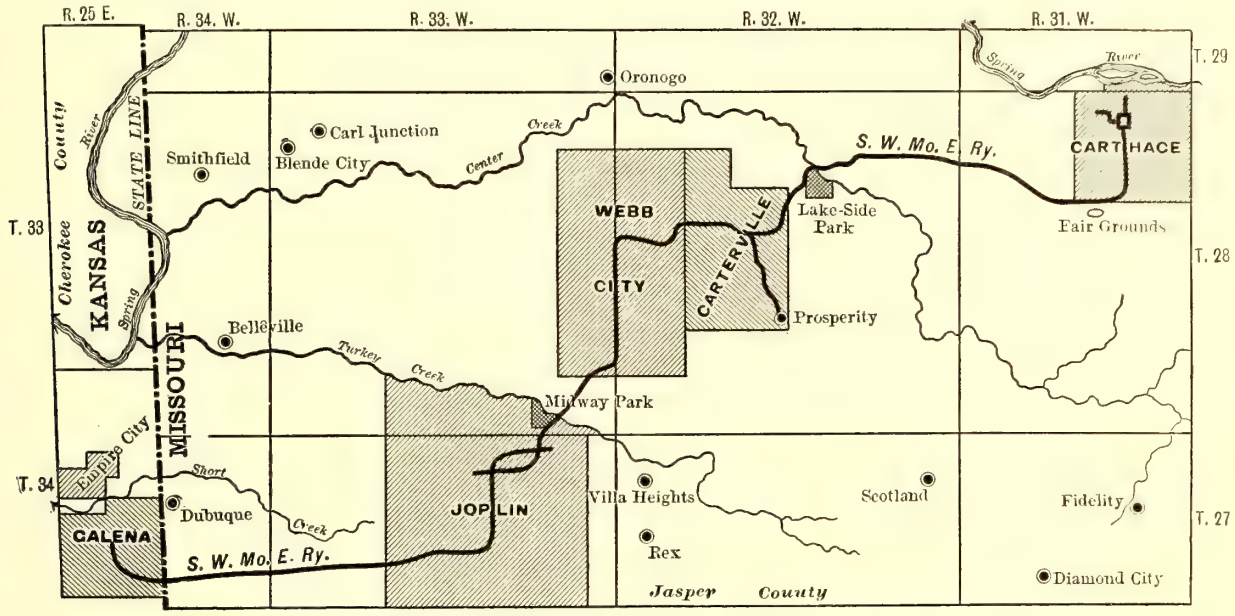
Three designs of split cast iron brackets are shown in 4, 5 and 6, Fig. 3. The two halves clamp the pole by two bolts which pull them together; the threads of the top bolt catch the whole strain in this method of fastening. The diameter of the pole at point of connection with cross arms can only vary 1 in. for this style of fastening. Instead of a cast-iron cross arm a sheet-steel punched cross arm,

made in two duplicate halves, is shown in 7 in Fig. 4. The elasticity of the two halves allows for considerable variation in the size of poles. Four bolts hold the halves together and either iron or wooden insulator pins can be used. Side arms are very useful in dodging trees; where the poles have to be set at a fixed distance from the curb the arm may be swung either side of the pole, and the feeders in this way cleared of tree contacts. Nos. 8 and 9 show the two, three and one pin arm method of fastening.

In some instances the feeders have to be supported on structures. No. 10 shows them carried under an elevated railroad. At *A* is shown the general arrangement, at *B* the suspension irons, at *C* the porcelain insulator, at *D* the spacing washer between insulators. A $\frac{3}{8}$-in. iron pipe threads these insulators; these supports are placed every 12 ft. to 25 ft. and no tie wires are used. No. 11 shows how a wire support is made where house connection can be made, but no pole can be set. The feeders are tied in the insulators in this case, and the span wire is also insulated by strain insulators.



Electric Railway at Amiens, France

The tramway system at Amiens consists of four lines, radiating from a central point and comprising about 18.7 km. of track. The entire system has recently been equipped electrically by the French Thomson-Houston Company, and is now in operation. The track is laid with 36-kg. Broca rails, and there are twenty-eight motor cars, each equipped with two 35-h.p. motors. The cars are divided into two sections, first and second class, each capable of seating ten passengers, while the two platforms together will hold eighteen passengers. The car weighs 8500 kg., and is capable of making speed at 25 km. per hour on a level.

The power station contains three 150-kw. units, with Corliss horizontal simple engines, with cylinder dimensions 560 mm. x 1220 mm., and running at 72 r.p.m. Each engine is belted to a generator of the six-pole type, and running at 400 r.p.m. The Standard overhead trolley system is used, and special attention was given to securing a light-appearing line by the use of ornamental poles.

Large Interurban Electric Railway in Southwestern Missouri

The Southwest Missouri Electric Railway is an evolution from a mule road, the only remaining vestiges of which are a wooden car barn, still used for a car house, and a few of the little cars, now in use as suburban passenger stations and as business quarters for a shoemaker and a newsdealer. The progenitive mule road to which reference is made was built in 1890 by A. H. Rogers, now president of the surviving company. It extended from the west end of Webb City to the east end of Carterville, a distance of $2\frac{1}{2}$ miles, and was operated with mules from Sept. 1, 1890, until March 1, 1893, when it was sold to the present company, reconstructed and extended from its former Webb City terminus south and west to Joplin, a distance of 6 miles, and from its former Carterville terminus east and south a distance of 2 miles to Prosperity, a rich mining camp.

MAP OF SOUTHWEST MISSOURI ELECTRIC RAILWAY

In 1890-'91 an electric railway was built in Joplin, extending from East Joplin to and through Joplin proper and to the suburb of Blendville—just south of Joplin—a distance of 5 miles. This railway was absorbed by the Southwest Missouri Electric Railway Company in 1895, and in 1896 was extended from the Blendville terminus west to Galena, Kan., a distance of 7 miles. In 1895 an electric railway was constructed from Carterville to Carthage, a distance of 12 miles; this property was also purchased in 1896 by the Southwest Missouri Company. Thus, at the present time the Southwest Missouri Electric Railway Company owns and operates an interurban electric railway system, the main line of which connects Carthage, Carterville, Webb City and Joplin, Mo., and Galena, Kan., with branch lines; Carterville to Prosperity, Joplin proper to East Joplin, and Carthage square to the two railway depots. In addition to the interurban service given, a city service is maintained in Joplin and in Carthage. The total mileage is 35.

Carthage, the eastern terminal of the system, is the county seat of Jasper county, and was a town of considerable size long before any of the neighboring mining towns came into existence. It contains many handsome residences, fine churches, good schools, and is enjoying a healthy growth. Carterville and Webb City are twin cities, whose existence is due to the discovery in 1873 of

rich deposits of lead and zinc in Center Creek bottoms, between the two town sites. Both of these places are prosperous, well-built towns. The main office, main power house and car house of the electric railway are in Webb City, as geographically it is in the center of the system. Joplin came into existence in the year 1869 as a mining camp pure and simple, and has grown to be a considerable railroad center, as well as a mining metropolis. Here are located large foundries, machine shops and smelting works, and the city is the headquarters of the zinc interests of the United States. Galena, Kan., is a typical mining town, and a good portion of the town site, as well as its contiguous area, is devoted to mining. The weekly output from the Galena mines alone will average $50,000.

The value of the output of zinc and lead ore from what

POWER STATION AT CENTER CREEK

is known as the Joplin district, for 1898, was $7,500,000; for 1899 it will reach $10,000,000. In 1895 the average price for zinc ore (Jack) was $20 per ton, now it is bringing $43 per ton. The population of Carthage is 12,000; of Carterville, 4500; of Webb City, 7500; of Joplin, 20,000; of Galena, 10,000.

POWER STATIONS

The power houses of the Southwest Missouri Electric Railway Company are two in number; one is in Webb City, the other at Lakeside Park. The Webb City station is of brick, 71 ft. x 140 ft., and the engine room is 71 ft. x 80 ft.

The equipment consists of one G. E. 225-kw. M. P. generator, belted to a single expansion Cooper-Corliss engine, and two Westinghouse M. P. 150-h.p. generators, each belted to a single expansion Cooper-Corliss engine. In addition, this station contains two D-62 generators used as boosters for furnishing power to the Galena section of the road, the extreme end of which is 15 miles from this power house. The boiler room measures 71 ft. x 45 ft., and contains five tubular boilers. Back of the boiler room are the coal bins, into which coal is dumped directly from the car standing on a private switch. Water for this plant is obtained from a well 250 ft. deep, and passes through a Cookson 1000-h.p. heater.

The power plant at Lakeside Park, on the bank of Center Creek, is a combination station and car house. This building is 90 ft. x 115 ft., and is equipped with two condensing Bates-Corliss engines, each driving by rope transmission a Walker M. P. 200 kw. generator. The boiler room measures 45 ft. x 45 ft., and contains two tubular boilers.

The voltage carried at the power house is 600 on the generators and 800 on the boosters. The greatest drop at any place on the line is down to 450 volts, under heavy loads.

The company has three car houses, one at Lakeside Park, as stated, one in Webb City, and one in East Joplin. During the present season an additional car house will be erected at Galena.

TRACK AND ROLLING STOCK.

Cedar poles and No. 0 trolley wire are used in overhead construction, and the track bonding is made up principally of No. 0000 copper bonds, though a number of plastic bonds are also in use. The feed wire comprises nearly 300,000 lbs. of copper. Double poles and span wire overhead construction prevails throughout. The overhead material is General Electric make, and the copper bonds were supplied by the American Electrical Works.

The track is laid with 50-lb. T rails throughout, except on Main Street, Joplin, and Main Street, Galena, where 56-lb. girder rails are employed. These rails are spiked to white oak ties of standard railroad size, and the entire roadbed is ballasted with tailings from the mining plants. These tailings provide a ballast that tamps nicely, and afford an easy-riding and solid track.

The two main streams crossed—Turkey Creek, near Joplin, and Center Creek, between Carterville and Carthage—are spanned by steel truss bridges resting on cut-stone abutments.

The rolling stock consists of ten single-truck cars, twelve double-truck closed cars, eleven double-truck open cars and three trail cars. The cars are heated by electric heaters and Baker hot-water heaters, and all interurban cars carry Wagenhals electric headlights. The motor equipments are made up of S. R. F. 30, G. E. 1200, Walker

STANDARD DOUBLE TRUCK CAR IN JOPLIN

5-A, Westinghouse No. 3, No. 12-A's, No. 49 and No. 38-B motors. The electric heaters are of the American and Consolidated types.

The managers of the company state that they have not yet found any trolley wheel that can always be depended upon to stay on the wire. The main remedy for the trouble of trolleys jumping the wire is found in good line work and attention to the trolley rope by conductors while passing around curves, etc.

Two parks are owned by the company—Midway Park, near Joplin, and Lakeside Park, between Carterville and Carthage. The latter represents an investment of $20,000. At Lakeside the company owns a small hotel, surrounded by a beautiful lawn, for the convenience of its employees

at the Lakeside station and car men whose run is out of the Lakeside car house.

Very little trouble is experienced in the country sections with snow, as the snow does not get deep enough to interfere with the operation of the cars. In the cities, however, it does become an obstruction. The company owns a snow plow of its own manufacture, which is used in cases of deep snows, but for the average storm, where only the city streets are to be contended with, the main reliance is placed upon salt. One salting of the track will not only remove an existing snow, but will also cause the next one that falls to melt rapidly.

CAR SERVICE

The interurban car service is divided into two divisions —the eastern and western. The former is between Joplin and Carthage, and is approximately 20 miles in length. On this division regular cars leave each terminal every thirty minutes from 6 A. M. until 11 P. M., and reach the opposite terminal one and one-half hours later. To this regular service the company added on March 1 a special service of fast electric cars known as the Empire County Express. These cars are operated every ninety minutes from 8 A. M. to 11 P. M., and reduce the running

VIEW OF TRACK BETWEEN JOPLIN AND WEBB CITY

time between Joplin and Carthage from one and one-half hours to one hour flat. Trips have been made by these cars in forty-eight minutes, including the four regular stops and four stops for railroad crossings, making an average running time of 25 miles per hour.

This fast car service, though operated over a single-track road, does not conflict in any way with the schedules of the slower cars, and has worked out to entire satisfaction from the outset. The cars used are new from the shops of Jackson & Sharp Company, and are mounted on Jackson & Sharp trucks. The bodies are 38 ft. over all, are fitted with smoking compartments, and (with motors) weigh about 31,000 lbs. each. They are equipped with hand brakes and heated with electric heaters. The motor equipments are G. E. 1200's and Westinghouse 38-B, one to each truck. The express service has proven a success, and seems to have increased the receipts of every car in service.

The western division is between Joplin and Galena, and is approximately 10 miles in length. On this division regular cars leave each terminal every thirty minutes from 6 A. M. till 11 P. M., and the running time is forty-five minutes from terminal to terminal.

The movement of the cars is regulated by a car dispatcher located at a telephone switchboard in the Webb City office. At each switch and terminal there is a telephone, through which the conductors communicate with the dispatcher and receive orders from him. The rules governing the telephone dispatching system are as follows:

"Cars must run as closely to schedule time as possible, and each conductor must communicate by telephone with the car dispatcher at time of leaving car house and at each passing point and terminal, wherever there is a telephone, and must govern the movement of his car strictly by orders received from dispatcher,

1000 FT. CURVE

proceeding from station to station only on orders. He must not allow his car to go beyond any meeting point without orders, whether he meets another car or not.

"When two cars meet, the conductor of the car first to arrive will report, and repeat orders received, to both his own motorman and to the conductor of connecting car, and the motorman of latter must not proceed till ordered or signalled so to do by his conductor.

"No extra car nor work car must leave the car house without reporting to and receiving orders from the dispatcher, and all such cars must move only in accordance with orders received from dispatcher."

When the express car service was started a great deal of dissatisfaction was manifested by patrons of the line who were accustomed to take the cars at points where the fast

OPEN CAR AT LAKESIDE PARK

cars would not stop, and considerable trouble was experienced in overcoming their objections, but nearly every one has now adapted himself to the new order of things, and peace prevails. This, and similar instances, show that a large amount of diplomacy is required on the part of the manager of an interurban railway in dealing with different communities and adverse personal interests; but it has been shown to be a fact that adherence to principles of equity

and fairness by the management of such an enterprise will silence factious opposition.

FARES

The fare from Joplin to Carthage is 20 cents. Express cars do not stop at any 5-cent collection point, and on these cars fares are collected in two instalments of 10 cents, and are rung up as collected. On other cars between Joplin and Carthage, which stop everywhere, fares are collected from passengers' starting point to destination at one collection, and identification slips are given him, a yellow slip indicating 10 cents, a green slip 15 cents, and a red slip 20 cents. At each regular collection point the conductor starts at the front of the car and rings up one fare for each passenger, gathering up yellow slips on second collection, green ones on third and red ones on fourth.

The fare between Joplin and Galena is 10 cents, and is collected and rung up one fare at each collection point.

The company's rule respecting half fares is given below in full:

"Children over five years of age and under twelve are to be carried for half-fare, but the half-fare privilege is to be strictly confined to children between ages above stated. Conductors will keep a supply of half-fare tickets on hand, and all transactions with half-fare passengers must be with half-fare tickets. Conductors will sell one half-fare ticket for five cents, punching same in presence of passenger from whom the five cents is received; this is not to be rung up, but on next collection the ticket is to be taken up and rung up. A half-fare ticket in possession of a half-fare passenger, if punched with the regulation punch mark, is to be accepted for one half-fare and rung up. Half-fare tickets are to be punched only in presence of passenger, and half-fare tickets when taken up, must not be reissued."

This system has in several years of practice proven that it overcomes all objections to ordinary methods of handling half fares. The conductor buys these tickets at the office for 5 cents each, and issues them as provided in the rule given.

Free transportation is given to those so favored in the form of coupon ticket books—each book containing 100 coupons. These coupons are accepted by the conductor as of the value of 5 cents each, and are rung up as other fares. Virtually no transfer system exists; the number of transfer tickets issued per day by all the conductors will not average more than twenty-five.

No freight is carried except such as can be taken on the front platform of the passenger cars. Each conductor carries a schedule of rates to be charged, and conductors are allowed to retain 20 per cent of all money received from this source, dividing it with his motorman. The charge for a trunk or baby carriage is 25 cents, regardless of distance, and for a bicycle 10 cents. The conductor issues to the passenger a receipt for amount received for carrying his freight, and turns in stubs to office.

Between July 11, 1897, and Jan. 8, 1899, the company maintained a rate war with a parallel steam road, as described elsewhere. The total receipts for the year ending Aug. 31, 1897, were $117,127.53, during this year being free from steam competition up to July 11, 1897—ten and one-half months. The total receipts for the year ending Aug. 31, 1898, were $115,050.11, in spite of fierce steam competition during the entire year, and with rates cut to one-third of the regular amounts after June 5.

The partial restoration of rates on Jan. 8, 1899, had an immediate effect in increasing receipts, and the addition of the rapid service between Carthage and Joplin, inaugurated Mar. 1, had a still further effect—the receipts for March, 1899, exceeding those of March, 1898, by more than $4,000, and were greater than for any previous month in the history of the road, in spite of weather very unfavorable for street railway operation.

Extensive additions and improvements will be made during the present year, particularly along the lines of increased motive power, greater car speed and additional rolling stock and equipments.

The officers and heads of departments of the company are: A. H. Rogers, president and treasurer; E. Z. Wallower, vice-president; A. G. Knisely, secretary; E. J. Pratt, superintendent of motive power; C. E. Baker, superintendent of transportation; J. M. Maret, superintendent of tracks, lines and bridges; H. T. Morrison, superintendent of repair shop.

Electric Railways in Europe

The accompanying table, taken from a recent issue of "L'Industrie Electrique," shows a summary of the length, station capacity and number of motor cars in the different countries in Europe, brought up to Jan. 1, 1899, with the totals at Jan. 1, 1898, for comparison:

Country.	Total Length of Lines in Km.	Total Power Capacity of Stations in Km.	Total Number of Motor Cars.	Character of Equipment.						
				Number of Trolley Lines.	Number of Conduit Lines.	Number of Surface Contact Systems.	Number of Accumulator Lines.	Number of Mixed Lines.		Total Number of Lines.
								Trolley and Accumulators.	Trolley and Conduit.

LETTERS AND HINTS FROM PRACTICAL MEN

Notes on the Standard Rules and Regulations as Reported by the A. S. R. A. Committee, IV

SCHENECTADY RAILWAY COMPANY,
SCHENECTADY, N. Y., April 19, 1899.

EDITORS STREET RAILWAY JOURNAL:

Continuing the comparison and analysis of the "Standard Rules and Regulations" of the A. S. R. A. committee, we wish to know:

10. Are they couched in plain, terse language, so as to be easily understood and remembered and—if necessary—memorized? This point has been partly answered previously (under head No. 5), but something more needs to be said on the subject, as the construction and language of the rules is an important point. The committee appears to have had a dread of "elegant phraseology"—whatever that may mean to them—and to have been led by that dread into phraseology that was inelegant, incorrect and misleading. To go over all the instances of this in the rules would be vexatious and tiring. We will be content with one of the worst specimens—Rule 33 for Conductors, which says:

"Lights: It is your duty to test lights and see that they are in good order before leaving depot, and you also must be very careful and particular that the headlight (in the direction the car is moving) is lighted, and must see that your car is provided with switch light plug before leaving depot."

The actual purpose of this rule of fifty-seven words can be much more clearly, correctly and thoroughly expressed in one of thirty-five words, as follows:

"Car lights: Before his car leaves the depot he will, by actual test, make certain that *all* lights are in good order, and that the necessary chimneys, the incandescent lamps and fuse links (or fusible plugs) are in their place on car."

The rule as given by the committee states that "it is your duty to, etc." This is entirely unnecessary, for if a certain instruction or command is placed in the rules, it goes without saying that it *is* the employee's "duty" to obey it, and—if it is addressed to one employee or class of employees—it is the "duty" of that employee or class of employees only. The same remarks apply also to the phrase "you also must be very careful and particular," and, in addition, this phrase is easily capable of a double meaning, either of which may be correct. As written, "you *also* must be very careful, etc.," it means that some one besides the conductor "must be very careful, etc.," whereas the true meaning of the phrase is "you must *also* be very careful, etc." In either case the language is unhappy, and if it means what it says, that the conductor is to be responsible for the burning of the headlight, that duty has already been placed on the motorman, under "Rule 17 for Motormen." It would certainly be poor discipline to give the motorman a specific duty, and under another head to give the same duty to the conductor. No specific duty capable of *always* being done by *one* employee should ever be divided among two or more. It divides the responsibility into fractions, lessens the interest of each one in that duty, and increases the chances of neglect. If a duty is so important that it must be done at all hazards, and if there is a fear that no one employee can be trusted to do it, it should be made the duty of some *official* to check its performance, but it should not be made the duty of a fellow employee of the same or inferior grade. In this instance the duty referred to is plainly the duty of the motorman—and no one else; for the headlight, whether it be oil or electric, is peculiarly the light of the man who runs the car, and on him should devolve the responsibility of seeing that it is in perfect order before he starts from the depot with it. He should be the one that should make certain that all necessary renewal parts liable to be needed while it is in use are in their place on the car, and on him alone should be the responsibility of its being lit at the proper time, and kept lit when and as long as it is necessary.

If we read the phrase the other way, as calling the attention of the conductor to the headlight as being the especial light to be looked after, it is still unnecessary, the italicised word "all" in the amended rule covering the ground thoroughly. The last part of this rule is unnecessarily verbose, and is also rendered obscure by the use of the local word "switchlight-plug." As this word is used in connection with the lights it is supposed to mean a "fuse-plug," "fusible-plug," or "fuse-link," either of which are better understood names for the article in question.

While a great many of the rules are unnecessarily loaded with words which frequently befog their meaning, others are so curt as to not fully express or explain themselves, or cover the subject of the rule. As has been stated in a previous article, "brevity must be sacrificed to perspicuity." A rule must, above all, be clear as to its meaning, but that clearness must be shown in the fewest and best chosen words; every word and sentence should be scrutinized and its meaning well weighed before it is allowed to go. All unnecessary words and phrases should be cut out—but no more. There is a happy medium between going naked and smothering one's self in unnecessary and clogging garments; and this applies to rules. Few people have the gift of extemporaneously saying the right things in the right words, and almost as few have the gift of writing them. It therefore behooves any one making a rule or order to see that it is first written so as to clearly express its full meaning and intent—that it is both clear and comprehensive—and after that is done to prune out the unnecessary words and phrases—to "boil it down to clear syrup!"

11. Are they arranged in some definite, connected and consecutive manner, and divided into groups having specific relation to certain persons, duties, responsibilities, acts or things? They certainly are not! To speak plainly, they are jumbled together in a very careless manner, and the employee who was compelled to pick out and remember the rules appertaining to him or his department would be entitled to hearty sympathy. While this point is not a vital one, while a set of good rules might be shaken up in a hat, printed as they come out, and possibly no great harm be done, still it would be easier for all concerned to have them in logical shape for better, safer and easier reference and remembrance. It costs very little in labor to put them in such shape if the principles that underlie such an arrangement are defined, understood and followed.

As a beginning, the rules in any one rule book should be consecutively numbered with a single series of numbers. There is no reason for numbering the "Rules for Conductors" with a series of numbers and the "Rules for Motormen" with a similar series, so that there is a "Rule 1" and "2" and "3," etc., for each. If it is desired to have the employee so conversant with the separate rules that they can be called to his attention and memory by number only, it will be just as easy for him to remember the first rule of his department as No. 19 as it will be if it is No. 1. Besides this, it is much easier for the superior officers or officials who have supervision over *all* the rules to remember them and place them if there is only one series of numbers. Finally,

it is much less productive of confusion and mistakes in notices or orders relating to the rules to have only one rule of each number instead of half a dozen "No. 1's" or "No. 9's," which depend for their identification on the name of some department or class being tacked onto them. The only reason for numbering as given by the committee is that it permits the addition of new rules at the end of those applying to each department without breaking the continuity of the numbers or using fractions or letters. In a well-considered and up-to-date set of rules the need of an absolutely new rule that cannot be temporarily added to an existing rule is—or should be—a rare occurrence, and where it does occur frequently it is a pretty sure sign that the rules, as a whole, need readjusting and rearranging. If, however, it is thought probable that there will be a need for additional rules before such a rearrangement is necessary, it is an easy matter and one productive of no evil or confusion to leave a few unoccupied numbers at the end of each section or department, these numbers to be given to the new rules as they are made.

Even worse than the system of numbering as adopted by the committee on some of the rules is the system of no numbers at all, as under "General Rules" and "Depot Masters," the designation of which could only be by "line No. so and so" or "paragraph such and such," a most cumbersome, confusing and impossible arrangement.

The first principle, therefore, in the arrangement of the rules is that all the rules in any one rule book should be consecutively numbered, without regard to departments or any other division.

The next point is to prefix each rule with a short heading, giving the object of the rule or the subject or subjects treated by it. In practice it is wise to have these headings printed in a display type, so as to quickly catch the eye of a person not familiar with the rules.

The next thing is to group the rules under proper heads or sections, relating to the departments, or classes or divisions of employees. As we are now considering only two classes, conductors and motormen, these groups will only number three—one for both and one for each.

The next is to subdivide these groups according to the relations of these two classes of employees. The relations that any traffic employee works under are as follows:

I. To his employer.

II. To his superior officers and officials.

III. To his subordinates.

IV. To fellow employees having the same duties as himself.

V. To fellow employees having different duties from himself, but with whom he will be thrown in working contact.

VI. To the materials, tools, apparatus, appliances or machinery under his charge, or used or operated by him.

VII. To the general public.

VIII. To persons not belonging to, or not having authority from his employer, but who may have relations with or authority over him under laws, ordinances, or general or local customs.

Keeping in mind these separate relations, the grouping of the rules for conductors and motormen naturally divides itself into:

A. An "Introduction" or "General Notice," in which the employer states the general duties, responsibilities, requirements, etc., common to all employees, and the principles underlying the duties of the employees for whom the rules following are made.

B. "General Rules for both Conductors and Motormen," stating fully their relations with their superior officers and officials, and with one another, with the general public and with outside parties in authority, where such relations are *general*, and identical for both conductor and motorman.

C. "Special Rules for both Conductors and Motormen," stating requirements, defining responsibilities and instructing in duties common to both.

D. "Special Rules for Conductor in relation to car."

E. "Special Rules for Conductor in relation to passengers."

F. "Special Rules for Motormen in relation to car."

G. "Special Rules for Motormen in relation to passengers and general public."

H. The bell and gong signals, and the rules specially and solely applicable to them.

I. Specific instruction in regard to special apparatus and localities, or to local customs, laws, ordinances, etc., relating to the employer—as represented by the conductor and motormen—or *directly* applicable to them.

Under these groups the rules should be arranged as much as possible in a natural sequence, taking up the different duties and responsibilities as nearly as possible in the same order as the employee will meet with them in actual practice. The following are given as suggestions for this arrangement:

Rule 1.—General requirements.
Rule 2.—Rules and orders.
Rule 3.—General conduct while on duty.
Rule 4.—"Time" and "Pay."
Rule 5.—Absence from duty.
Rule 6.—Resignation and discharge.
Under "Special Rules for Conductors and Motormen:"
Rule 10.—Uniforms.
Rule 11.—Badges.
Rule 12.—Other company property.
Rule 13.—Taking out and bringing in cars.
Rule 14.—Defects in track, line, etc.
Rule 15.—Articles sent by car.
Rule 16.—Disablement of car.
Rule 17.—Leaving car while on run.
Rule 18.—Disturbances, ejections, etc.
Rule 19.—Accidents.
Under "Special Rules for Conductor in relation to car:"
Rule 25.—Responsibility and authority.
Rule 26.—Care and condition of car.
Rule 27.—Trolley.
Rule 28.—Safety-gates, bars, nets, etc.
Rule 29.—Direction or route signs.
Rule 30.—Grade crossings.
Rule 31.—Place and actions on car.
Rule 32.—Articles left on car.
Rule 33.—Running and schedule.
Under "Special Rules for Conductor in relation to passengers:"
Rule 40.—Non-riders.
Rule 41.—Collection of fares.
Rule 42.—Keeping order on car.
Rule 43.—Conversation with passengers.
Rule 44.—Stopping for passengers.
Rule 45.—Assisting passengers.
Rule 46.—Looking out for passengers.
Rule 47.—Calling streets, etc.
Rule 48.—Platforms and steps.
Rule 49.—Smoking and spitting.
Rule 50.—Intoxicated persons.
Rule 51.—Disorderly persons.
Under "Special Rules for Motormen in relation to car:"
Rule 55.—Responsibility and authority.
Rule 56.—Who may run car.

Rule 57.—Care and condition of machinery and apparatus.
Rule 58.—Special points to be observed in relation to machinery and apparatus.
Rule 59.—Special points to be observed in regard to running.
Rule 60.—Speed.
Rule 61.—Headway.
Rule 62.—Schedule.
Rule 63.—Grade crossings.
Rule 64.—Right of way.
Rule 65.—Block of road.
Rule 66.—Sand boxes.
Rule 67.—Headlight.
Rule 68.—Track signals.
Rule 69.—Use of foot-gong.

Under "Special Rules for Motormen in relation to passengers and the general public:"

Rule 75.—Looking for passengers.
Rule 76.—Blocking of track.
Rule 77.—Ambulances, fire wagons, processions, etc.
Rule 78.—Alarms and warnings.
Rule 79.—Danger and risks.

After these may be placed the bell signals and all rules relating *exclusively* to them. Also, copies of, extracts from, or directions in regard to laws, ordinances, etc., to be observed, or peace or other officers to be obeyed or reported to.

Under each one of the above—or similar—headings should be grouped everything appertaining to the subject contained in that heading that applies to that particular employee or class of employees. The different divisions of this subject had best—for easy reference—be paragraphed. For instance, under "Rule No. 41.—Collection of Fares," should be stated in separate paragraphs the following points:

The different kinds and amounts of fares to be collected.
When and how they are to be collected.
When and how they are *not* to be collected.
When and how they are to be registered, or otherwise publicly recorded.
When and how they are to be privately recorded.
When and to whom they are to be "turned in."
Regarding errors in regard to collection of fares or of making change.
Regarding disputes concerning same.
Regarding errors in registering or recording fares.
Counting and checking passengers.
Instructions in regard to setting, changing, handling, etc., of registers or other recording or checking devices.
Change.
Tickets.
Full instructions in regard to transfers.
Free riders other than employees.
Riding of employees.
And any other specific instructions as to local or special procedure or customs regarding fares.

The above classification, grouping and paragraphing may seem like an appalling and unnecessary mass of detail, but nothing has been suggested but what is necessary to make the rules quick and easy of reference and easily remembered—surely two very important points. As to the number and title of heads, or rules, given, there are few but what are general and can be used in full by the smallest of roads, while a road much larger or more complex would very probably have to add considerably to their number.

H. S. Cooper.

(To be Concluded.)

Heavy Snows in Montreal

Montreal Island Belt Line Railway,
Montreal, April 11, 1899.

Editors Street Railway Journal:

On the introduction of electric railways into Canada it was prophesied that snow would be an insurmountable

DEEP SNOW NEAR MONTREAL

difficulty. I inclose a couple of photographs of "difficulties" on our line. This drift was so hard that it would hold a shovel so firmly that the latter could be broken off, and it would quite easily bear a man's weight.

This storm was fought with shovels and a Ruggles ro-

A TYPICAL DRIFT

tary plow, equipped with four G. E. 1200 motors. The plow alone would handle a considerable amount of soft snow, but banks of this description are not to be overcome by such mild persuasion. Some of our cars are furnished with noses, but are not of much use when the snow is too deep.

I may say that we have some 12 miles of track, on which the snow fell on March 28 to a varying depth of from 2 ft. to 10 ft., and all hard packed.

While the difficulty was not insurmountable, I think all will admit that it was a difficulty.

Our Lady of the Snows.

The Breakage of Car Axles

St. Louis Car Wheel Company,
St. Louis, Mo., April 14, 1899.

Editors Street Railway Journal:

I have read with interest the discussion in your columns on the breakage of car wheel axles, and think a large factor in accidents of this kind is the condition of the track. Where the railway has light T rails and bad joints, some disasters of this kind must be expected with light or low grade axles. It is also necessary to have the wheels properly adjusted to the track gage, for if too narrow between flanges they impinge on guard rails, in frogs and at crossings, and if too wide are grinding continually against the inside of the rail heads, all of which produces undue strains upon the axle. With 18-ft. closed cars bodies or ten-bench open cars, 33-in. wheels, good track and a speed not exceeding 12 miles an hour, an axle of $3\frac{3}{8}$ ins. diameter, if of good material, should stand all the proper strains that are likely to come upon it in service. We have fitted many hundred of wheels, a large proportion of which have been 36-in. wheels, upon axles of that size made of hammered steel, and I do not remember of a single breakage except in collision or derailment. It is supposed that the axles are properly trammed when under the cars; if not, that will cause another strain on the axle.

Our experience with rolled steel for axles has been most unsatisfactory, so much so that we have abandoned its use for axles entirely and use hammered steel instead, as mentioned above, and have found it most satisfactory. Again, a good many car builders and street railway superintendents (or their truck men) when pressing street car wheels on the axles leave them wide in the gage, making the flange run close to the rail in order to prevent lateral play on the car as much as possible. This is very good practice when the tracks are kept in first-class condition, straight and level, and when the rail joints are well kept up, but if otherwise, a close working flange is pretty severe on the axle, as the crowding of the flange, when added to the strain of the load bearing on journals outside of the wheels, tends to bend it continually.

Our practice in pressing on is to leave a little lateral play between flange and rails, and having received no "kicks" from our customers we consider the practice a good one. Alexander Magee, Foreman.

A Method of Increasing the Life of Gears and Trolley Wheels

Denver, Col., April 10, 1899.

Editors Street Railway Journal:

During the early and dark days of the electric railway we used a trolley wheel of about one-half the diameter of those required by modern practice, and pressed harder against the wire. When made of brass they would not last over three days, but the metal was gradually made harder, until finally we used steel, tempered file hard. These wheels proved to be desirable, electrically, and quite durable.

In later experiments with motors and boxed gearing, of my own design, to deaden the noise and lubricate the gears we supplied them liberally with common bar soap and oil. This proved to be quite desirable for the purpose intended. and besides it showed another remarkable feature. The face of the teeth of the gearing were soon covered with a thin scale of foreign material, which prevented the metal from wearing. This material became flint hard, and required a cold chisel to remove it.

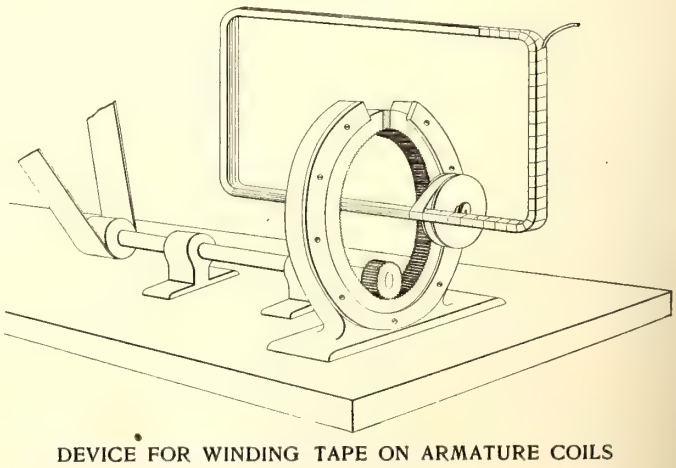
The writer is of the opinion that trolleys which will last ten times as long as those in common use, and car gearing that will not become noisy and wear, are within reach. I do not supply the exact specifications, but leave room for a little study and experimenting on the part of the railway master mechanic. John C. Henry.

Babbitt Melting Forge

Brooklyn, N. Y., April 4, 1899.

Editors Street Railway Journal:

In many shops it is customary to melt babbitt metal in the smith's forge—a very wasteful and vicious method, when it is considered that the forge fire gives too intense a heat for properly melting babbitt, and that babbitt metal injures the working of the forge whenever any of the metal finds its way into and remains in the tuyre. Lead there will effectually prevent the welding of iron as long as it is exposed to the action of the vapor of the lead.



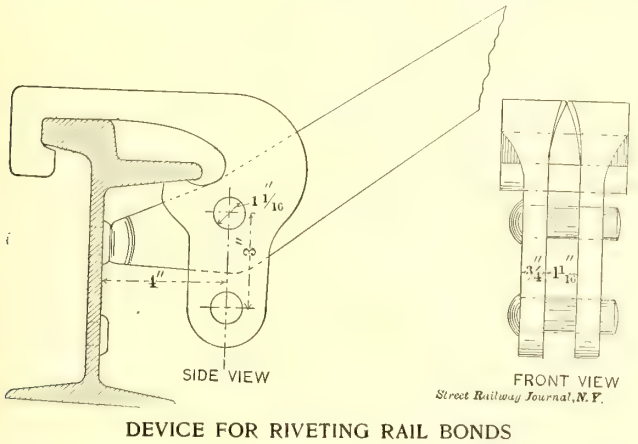
A much better way, and a cheaper one, too, is to rig up a little gas bench for the melting of small lots of babbitt. When a quantity of it is to be handled a furnace similar to that used for melting out—and melting in, too—the lining of axle and motor boxes will do. But, the gas bench, that is made of one or two heavy gas burners similar to those used in kitchens for cooking. They are placed in an iron bench, and proper iron bearers rigged for holding the ladles in place. With this rig the heat can be regulated at will, and there is no danger of melting out the bottom of the ladle before the workman is aware that it is even red hot and before the babbitt is fairly warmed through.

James Francis.

Quick Method of Winding Tape on Armature Coils

The winding of armature coils is a tedious and rather expensive job, on account of the labor required to wind the tape on the coil. Mr. Sheldon, of the Indianapolis Railway Company, has made a very ingenious and simple winding device by which the coil of tape is reeled around the armature coil. The accompanying engraving shows the general construction of this tool. The large external gear was cast from a lawn-mower casting, and gave very excellent results.

The spool on which the tape is wound is secured to a



DEVICE FOR WINDING TAPE ON ARMATURE COILS

stud projecting from the rotating internal gear wheel. In order to introduce this coil into the center of the rotating ring, a diagonal slot is cut across the gear, and when the slot is opposite the opening in the containing bearing for this ring the coil can be introduced into the center of the ring. The device is then started up, and the tape is wound

on the coil as it is fed along through the center of this rotating ring. More or less tension can be given to the spool containing the tape by increasing or decreasing the pressure on the friction surfaces. The ring makes about 60 to 100 r.p.m., depending upon the character of the coil. It gives excellent results, and labor can be cut down about two-thirds by the use of this machinery instead of hand work. The perspective drawing of this arrangement is shown in the engraving, and details can be changed to suit any conditions which the repair man may consider desirable.

Device for Riveting Rail Bonds

On the Cleveland Electric Railway an ingenious method of holding the rail bonds in place while they are being riveted is employed. This consists of a hook lever, which is

DEVICE FOR RIVETING RAIL BONDS

placed over the head of the rail, and to which is connected a long bar which can be brought with heavy pressure against the head of the lug. This holds the rivet firmly while the riveting takes place. The arrangement is shown in the accompanying diagram.

Accident Instructions

The New Orleans Traction Company has recently issued such a set of instructions for government of its employees in case of accident, which gives in concise form the rules to be followed in case of accident. These instructions are printed on a large sheet, and have been posted in all the stations of the company.

The company has adopted the custom of teaching the employees topically by large cards of this kind, each referring to some special field of their work, rather than to embody the rules governing their duties in a book. This practice has been adopted because it has been noticed that by posting in the conductors' and motormens' rooms separate cards for the several sub-divisions of their duties discussion is more likely to be provoked, and this seems to breed greater familiarity with the subjects presented.

The company has been giving some special attention to the matter of accidents, with the result that its record during the past year has shown about 33 1-3 per cent improvement as compared with the previous year, with a 26,000 car-mile daily run.

ACCIDENTS

The term ACCIDENT includes injury to PERSONS or PROPERTY, COLLISIONS, BREAKAGES of all kinds to the CARS, EJECTIONS, PERSONAL TROUBLE in car between EMPLOYEES and PASSENGERS, or between PASSENGERS, and any event of any name or nature occurring upon a trip, wherein damages occur to PERSONS or THEIR PROPERTY, to CAR, to VEHICLES, or wherein the possibility of damages may arise from any action of EMPLOYEES or PASSENGERS themselves, whether complained of or not.

CONDUCTORS are not permitted to use discretion as to reporting or not any occurrence included in above statement, but must report promptly all matters coming within above list.

Reports must be TRUTHFUL and state EXACT facts, without FEAR, FAVOR or PREJUDICE, and no attempt must be made in a report to SHIELD any employee, or to CONCEAL any of the circumstances surrounding the occurrence reported. Reports must state FACTS which can be SWORN TO IN COURT by the employee reporting or by the party or parties named as witnesses. INFERENCES, OPINIONS and SUGGESTIONS must be stated as such, and not as facts. Report must give:

1st. DATE OF ACCIDENT AND EXACT TIME OF DAY WHEN IT OCCURRED.

2d. EXACT PLACE OF OCCURRENCE; full name and address of party injured, or likely to have been injured, either in person, property or feelings; the owner of property damaged or doing damage to company's property; if vehicle, name of driver, license number and year of issue.

3d. NATURE OF ACCIDENT, and cause of its occurrence. THIS CAUSE MUST BE CAREFULLY ASCERTAINED.

4th. FULL NAME AND ADDRESSES of all passengers, bystanders, and employees, as far as possible, whether they saw how the accident happened or not.

5th. DISTANCE WHERE CAR STOPPED, after the accident happened, from place on the street where accident occurred; measurement to be made by stepping the distance from the front end of car to point of accident. This measurement should be witnessed by a bystander, or some one not connected with the company.

6th. Statement of injuries or damages as well as any expressions of opinion from bystanders regarding the accident.

Above report must be filled out upon blank for that purpose, signed by the conductor and motorman, and left at the station, after turning in the car.

In the event of personal injury, care must be taken to render all the necessary assistance and attention to person injured.

The most TRIVIAL and apparently UNIMPORTANT ACCIDENT or OCCURRENCE in or about the car, even where a person declines to give name, claims no injury, or seems to regard the whole matter as trifling, must be REPORTED with as much care as though the damage or affair was of the utmost importance.

All accidents must be telephoned to general office of company as soon as possible, and especially in the event of a serious accident, the general office must be notified IMMEDIATELY so that prompt aid may be furnished and investigation begun pending the full report.

It is expected that a report will be made of all accidents or injuries that may occur on the track, or within 10 ft. of same, whether the car was concerned in the accident or not.

Attention is specially called to question arising between CONDUCTORS and PASSENGERS, as to the PAYMENT of fare, CHARACTER OF MONEY OFFERED, CHANGE FURNISHED, TRANSFERS or other COMPLAINTS leading to DISORDERLY, or BOISTEROUS conduct, in each of which events conductor must secure POSITIVE PROOF and EYE WITNESSES, so as to be able to clearly substantiate the truthfulness of his report in court, particularly before any EJECTION or ARREST is attempted, and full report of same must be promptly made in accordance with above rules. NO EJECTION must be made without FIRST REFUNDING FARE.

Conductors or other employees MUST NOT TALK about, or GIVE ANY INFORMATION WHATEVER concerning an accident to any person, other than the proper officer or person delegated with the authority of the company to investigate the occurrence, and all questions asked of any employee of company, except by person or persons above named, must be answered by directing the questioner to general office for information.

Employees must not VISIT an INJURED PARTY, or FAMILY, to make inquiries or discuss accident without authority of company.

The above rules must be STRICTLY OBSERVED, and too much stress cannot be laid upon their importance. If any doubt as to their meaning in any respect exists in the minds of employees, they should consult, for their own protection and the company's, their station foreman.

C. D. WYMAN, General Manager.

New Orleans, La., April, 1899.

Cars should be sponged off daily with clear water, and any accumulation of dirt removed as far as possible with a chamois skin and sponge—care being taken to rinse off the grit before rubbing with sponge or chamois. Once every thirty days the car should be thoroughly washed down, using a good grade of soap. From paper at the Boston Convention, 1898.

STREET RAILWAY JOURNAL

MAY, 1899.

PUBLISHED MONTHLY BY

In all Foreign Countries, per annum.....$6.00 / 25l / 31 fr

Subscriptions payable always in advance, by check (preferred), money order or postal note, to order of C. E. WHITTLESEY, Treasurer.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

The theorists and social reformers who claim to represent the enlightened and progressive element of the people of New York, but who certainly do not speak for the millions of "strap hangers" who suffer daily discomforts in the travel to and from their business, have succeeded in influencing Governor Roosevelt to take a somewhat decided stand against the granting to the Rapid Transit Commission of the City of New York the power to confer a perpetual franchise upon the group of capitalists which was prepared to spend $60,000,000 in bringing about genuine rapid transit in the boroughs of Manhattan and The Bronx. The offer to expend this money has therefore been withdrawn, the Metropolitan syndicate stating in a characteristically direct and candid manner their unwillingness to appear before the public as a "grabber of franchises," and their equal unwillingness to expend so large a sum of money upon a short tenure of privilege. It is hardly to be believed that so favorable an opportunity to secure a great public benefit at private expense and risk should be allowed to pass away, but it is impossible not to see that the growing tendency in municipal administration is to drive the hardest, sharpest bargain possible with public service companies, obtaining for the city treasury the last penny of profit, and leaving to the companies little margin for the larger improvements and extensions which are often unprofitable at first, but which the future would justify were the conditions more secure and the bargain more equitable. The people will inevitably suffer in the long run from a narrow money-making policy of this kind, but the latter is popular, and enables astute politicians to court and win public favor and office.

* * * * * *

The really incredible thing is that a man so broad-minded and sensible as Governor Roosevelt should be impressed with so superficial a view of the true interests of the city of New York as is taken by the "reformers," and should be so deceived by the sophistry of their arguments. Again and again have the opponents of a perpetual franchise urged the impossibility of making a bargain to-day which would properly protect the city's interests one hundred years hence. Again and again have they calmly ignored the workings of the Metropolitan syndicate's proposition to pay 5 per cent of the gross receipts to the city, and have wilfully or carelessly asserted that the city would get no more in future than at present. What are the real facts of the case? They are, obviously, that, as the travel increases with increase of population, the city's revenue increases in the same ratio. Moreover, this 5 per cent of the *gross receipts* really means a far larger percentage of the *net profits*—a percentage so large as to amount to a very profitable "special partnership" obtained by the city in the rapid transit enterprise. As we do not remember to have ever seen the real character of this "special partnership" clearly brought out and explained in the many discussions in different cities about the proper basis of franchise remuneration, it is worth while here to show in some detail exactly what "5 per cent of the gross receipts" really means in this particular case.

Clauses 7 and 8 of the Metropolitan syndicate's proposition read as follows:

7. The city to receive as compensation, in addition to the services rendered and in lieu of all other charges upon the franchise granted hereunder, an annual rental equal to 5 per cent on the gross receipts from the operation of the new road, provided that whenever any such payment shall leave the receipts insufficient to pay the rental of 5 per cent on cost of construction and the operating expenses, including taxes, the percentage to be paid shall be abated accordingly.

8. The real and personal property forming part of said railway to be exempt from taxes until it pays 5 per cent, as provided in section 15 of the rapid transit act, with the amendments proposed by the commission in the bill now pending before the Legislature.

If the new tunnel railway earns, in competition with the present surface and elevated lines, $7,500,000 gross per annum, or nearly as much as the present Manhattan elevated system is earning, and expends 50 per cent of this sum in operating expenses proper, it will turn over to the public treasury, in the form of taxes on real and personal property and agreed rental to the city not less than 10 per cent of the gross receipts, or $750,000, and will have left for its stockholders their 5 per cent guaranteed rental upon

their $60,000,000 investment, or $3,000,000. In other words, $7,500,000 is the minimum gross earning power of the tunnel railway by which its projectors will be able to make 5 per cent interest upon their investment and pay all the city's rental and taxation charges as agreed. Under these circumstances, and assuming this $3,000,000 to be merely "interest," and not in any sense "profits," the public would obtain all the "profits," leaving nothing for the controlling syndicate; or, put in another way, the public would obtain 20 per cent of the entire earnings from operation applicable to return on investment without itself making any investment whatsoever. Now, what may be expected of the future? Suppose that with the increase of population there comes a proportionate increase in traffic, such that fifty or one hundred years hence the tunnel railway will earn $25,000,000 gross. It cannot, of course, do this without making constant additions to its capital account in the way of extensions, increase of equipment, etc., and we will be well within limits in taking the aggregate investment account for a $25,000,000 gross earning power at $80,000,000. Let us see, then, what proportion of the earnings from operation and of the true profits the public would obtain at various stages of development between these maximum and minimum limits:

Investment.	Gross Earnings.	Operating Expenses.	Interest on Investment.	Rental and Taxes 10 per cent.*	Profit to Private Capital Above. Interest on Investment and Taxes.
$60,000,000	$7,500,000	$3,750,000	$3,000,000	$750,000	———
65,000,000	10,000,000	5,000,000	3,250,000	1,000,000	750,000
70,000,000	15,000,000	7,500,000	3,500,000	1,500,000	2,500,000
75,000,000	20,000,000	10,000,000	3,750,000	2,000,000	4,250,000
80,000,000	25,000,000	12,500,000	4,000,000	2,500,000	6,000,000

* The average city and State taxes paid by the Manhattan (Elevated) Railway Company of New York during the last five years amount to 7.2 per cent of the gross receipts.

It appears from this table that, as before stated, on a basis of $7,500,000 gross earnings the public will get all the profit above the interest, and private capital nothing; with $10,000,000 earnings the public will get 57 per cent of the profits and private capital 43 per cent; with $15,000,000 earnings the public will get 37½ per cent of the profits and private capital 62½ per cent; with $20,000,000 earnings the public will have 32 per cent of the profits and private capital 68 per cent; and with $25,000,000 earnings the public will have over 29 per cent of the profits and private capital less than 71 per cent. Even at $50,000,000 gross earnings, assuming $100,000,000 accumulated investment, the public would obtain 25 per cent of the profits above interest. In all cases the public will get 20 per cent of the entire net earnings. Does this partnership seem inequitable or against good public policy? Can the social reformers really hope that a municipal administration can so manage an enterprise of this highly technical character as to surely bring a larger sum into the public treasury, and at the same time to serve the whole public as well as can be done through private enterprise? Can Governor Roosevelt himself, with his intimate knowledge of the way in which public affairs are conducted by politicians, really believe that better results to the public can, in the long run, be obtained by municipal ownership or management?

* * * * * *

There are other phases of the Metropolitan syndicate's proposition which do not seem to be clearly appreciated by the public. The State does not hesitate to grant to a steam railroad company a perpetual franchise and the right of eminent domain, by which it can lay out a route across fields and roads and through cities and towns, as it pleases, and own such route forever. Why, therefore, should private capital be debarred from undertaking the work of constructing a tunnel beneath the surface of a city at an expense per mile enormously greater than any railroad is called upon to bear? Again, one of the chief advantages of the present proposition for rapid transit in New York lies in the surface connections and transfer arrangements, by which the surface system acts as a collecting and distributing agent for the subway. The Metropolitan Street Railway Company's surface franchises are perpetual, and even if a short-time franchise only were granted for the tunnel, with a provision for revaluation at the end of each of successive periods, the city would practically be forced to come to the terms of the surface railways in order to maintain the advantage of the distributing and collecting media. In spite of the withdrawal of the Metropolitan propositions, we sincerely hope that some means may be found to bring about rapid transit in New York at the earliest moment. The tunnel is an inevitable necessity, however long its building be postponed, for it will be wholly impossible five or ten years hence to carry on the surface or elevated lines of the city the people who will demand transportation facilities. The city is growing at so rapid a rate and the lines are, even at present, so congested with traffic, that nothing is more sure than that in some way new facilities must be provided.

It looks as if we were to have a municipal ownership experiment in Detroit, and perhaps another in Toledo. On the whole, we are inclined to welcome the carrying through of such a proposition in a single American city, feeling confident, as we do, of what will be the result. Perhaps it is as well, too, that Detroit is the first city selected to enjoy the benefits of municipal ownership so freely promised by "Pingreeism," for three-cent fares are already established in that city on many of the street railway lines, and we presume that the first decision made by the new owners will be to reduce fares to this figure on all. If a municipality can operate a street railway system on a three-cent fare basis, and make money in doing it, we all want to know it; while the cost of the experiment, if unsuccessful, can be distributed upon the large mass of taxpayers with less individual suffering than upon a smaller group of street railway stockholders. A month hence we hope to know on what basis the purchase is to be made and the possibilities of profit or loss to the city.

It is becoming more and more a recognized fact that electric railway operation is more akin to steam railroad operation than to the former horse car service, so far as the duties and abilities required of the employees are concerned. The modern electric car is a machine, not an omnibus, and all machinery such as that carried on a car should be in charge of persons having a knowledge of its proper maintenance. An example of the increasing similarity of electric cars with steam locomotives, and the necessity of the establishment of a proper system of inspection and supervision is illustrated by the increasing use of air brakes. We believe that where this type of brake is employed good results would be obtained by an extension of the system of training to this part of the equipment.

This is not founded upon the ground that the air brake is a more delicate part of a car equipment than the motors or controller, but as any piece of machinery can be abused by unintelligent handling, there is no more reason why street railway companies should not instruct their employees as to the proper method of handling street car brakes than steam railroad companies. The history of the latter has shown that the best results follow the establishment of schools for instruction of employees as to the operation and inspection of air brakes, and that the outcome warrants the expenditure of the effort has been proved beyond the possibility of doubt.

An exceedingly interesting and able argument in rebuttal of the excessive claims for taxation of street railway companies by municipalities was recently presented by John W. Boyle, president of the Utica Belt Line Street Railroad Company, in an attempt in that city to compel a railway to pay for the cost of pavement between its tracks and for two feet outside. The question is discussed from both a legal and a moral standpoint, and while Mr. Boyle takes occasion to point out a number of the popular fallacies and prejudices under which the railway company has to labor, he shows that while more beneficial to a city than a manufacturing establishment employing the same number of persons, it differs from the latter in that when overtaxed and persecuted it cannot shut down or remove its plant to another city, and for this reason is made the target of all kinds of oppressive measures. The pavement tax is particularly onerous in that the railway company is probably the only taxpayer which does not use one foot of the pavement, but furnishes and keeps in repair, at its own expense, that portion of the street on which its wheels revolve; in fact, a good pavement is a detriment to the railway company, if it exercises any effect upon its business. The usual argument, Mr. Boyle contends, for assessing railway companies is that they occupy the streets, and have thus a valuable franchise. While it is true that the cars are on the streets, this also applies to other vehicles, the only difference being that a car occupies, in proportion to the number of persons carried, a very much smaller proportion of the street than do the other vehicles, and that, while on the street, they have no exclusive right of way, but are bound under the most strict penalties, in the way of damages from accidents, to avoid collisions with other occupants. No one ever rides in an electric car under compulsion, or for the benefit of the railroad, but solely for his own convenience, and if a person decides the convenience is not worth the nickel, he keeps the nickel and walks. It is no answer to this to say that many ride from necessity, because the exigencies of their business demand it, and pay the fare under protest. There are people who pay under protest for the food they eat and the clothes they wear; but when the food has been furnished them at the lowest market price, and the clothing for less than any other merchant of the city sells it, the protest carries little weight. If people ride from necessity, then the railroad becomes a necessity to the city, which is what the railway companies claim. Altogether, the argument, which is printed in pamphlet form, will be found most readable and valuable.

It is not often that the engineering public has the privilege of reading and digesting such a clear, intelligent and convincing report on the electrical equipment of a large city tramway system as has just been presented to the Glasgow Corporation by H. F. Parshall, its consulting engineer, a full transcript of which appeared in our columns last month. Not only are such reports in this country presented to the directors of private companies and jealously withheld from the public, but electric traction in this country has been more a matter of development in each city than of the intelligent laying out of complete plans beforehand. Great Britain is fortunate in having an opportunity of drawing upon the world's experience in the construction of municipal and private plants, and we have no doubt that the opportunity will be taken advantage of in a majority of cases. Mr. Parshall's experience has been so wide and his practice so uniformly successful that his recommendations to the Glasgow Council have peculiar weight, and may well be studied by street railway managers in America, as well as in Europe. His most important recommendation is that a high tension three-phase main generating station, with several rotary transformer sub-stations, forms a system of generating and distributing power more economical than is that of several separate 500-volt direct-current generating stations. This is undoubtedly the best engineering practice of to-day, as shown by the decisions in its favor made by the Metropolitan and Third Avenue companies in New York, by the Edison Electric Lighting Company of Brooklyn, and by the Central London Underground Railway. The advantages are a less capital expenditure in buildings, generating plant and real estate; greater latitude allowed in the selection of a power station site, where coal and water can be obtained at minimum cost; less working cost for labor and repairs, due to the minimizing of the skilled force necessary for operating the plant, and to the economy always found in the operation of large instead of small units; the greater flexibility of the system with respect to future extensions, and the placing of new sub-stations wherever desired; and the relatively shorter time taken in constructing the plant, by which the superior economy of electric traction over horses can be more quickly realized. Mr. Parshall's estimates of the relative investment costs and operating expenses of the two forms of generating and distributing plants is interesting. For the three-phase rotary converter plan, the investment cost is placed by him at $1,580,000, while for the five separate generating stations it will be $1,950,000, these figures not taking into account cost of ground and railway connections, which, if included, will bring about a result much more favorable to the single generating station. The total power operating expenses for the three-phase system, exclusive of maintenance, depreciation, interest, insurance and taxes, are estimated by Mr. Parshall at $.0046 per kw. hour, and including maintenance and fixed charges, at $.0106; while the power operating expenses proper for the direct current generating stations would be $.0075, and including depreciation and fixed charges, $.0147. These figures do not include interest on the cost of sites and railway connections. The annual estimated saving in Glasgow in using the tri-phase distribution, based on a 600-car plant, is estimated by Mr. Parshall at over $100,000.

A Formula for Train Resistance

BY HENRY GRAFTIO

The question of train resistance is one that has attracted the attention of many prominent engineers. Besides the high scientific interest which the subject posseses, it has also a practical value of the highest importance, for a more accurate knowledge of all the factors of train resistance can only contribute to the finding of means to diminish them. As the STREET RAILWAY JOURNAL has been paying particular attention to this subject during the past few months, it may be of interest to its readers to have given briefly some of the results secured abroad in investigating this problem.

During the last few years some very interesting and complete tests on the resistance of trains and locomotives have been made in France. Some of these tests indirectly, and some directly, are likely to confirm the opinion expressed by Mr. Angus Sinclair, of "Locomotive Engineering," and of Mr. Lundie, that at high speeds the resistance of trains seems to increase as the first power of the speed. For a long time the general opinion prevailed that the resistance of trains must follow a parabolic law. This was due in a large measure to the general adoption of the well-known formula of Newton.

$$R = k S v^2$$

for the resistance of a moving plane surface in free air. But all evidence now seems to prove that this theory is wrong. As it is quite impossible to find an expression for air resistance on moving bodies by pure mathematical deductions in the present state of our knowledge of aerodynamics, it is manifestly wrong to admit *a priori* for air resistance, a theoretical expression similar to that of Newton's, or by finding by experiment within restricted limits—coefficients more or less accurate to extend their application to limits outside of the experiments.* Only experiments made on very large scale can be considered as reliable.

Among the experiments on air resistance those of Mr. Crosby occupy in the mind of the writer one of the first places, being conducted on a very large scale and with bodies that were really moving in the air. Mr. Crosby's curves† are represented in Fig. 1. Some experiences on air resistance made in France seem to contradict these results; but this is due almost entirely to the fact that in investigating the laws of air resistance Newton's formula was adopted *a priori*, and all efforts were directed to find the most probable value for k. Thus M. Poncelet expressed the opinion that up to 50 km. the resistance of air on a parallelopiped body is practically expressed by Newton's formula by putting k. = 0.08. Messrs. Cailletet and Colardeau, from experiments made on the Eiffel Tower, consider this value to be too large and within the limits 0 km. to 90 km. per hour, consider k. = 0.07. But here was another cause for error, viz.: the fact that the velocity of the wind was measured by anemometers, and therefore not in so accurate a manner as by the speed of moving bodies as in Mr. Crosby's tests.

The noteworthy and most reliable experiments made on train resistance in the United States by a great specialist on this subject, Mr. Angus Sinclair, invariably showed at high speeds the relation

$$R = a + bv$$

between the limits of 60 km. and 120 km. per hour, and the no less remarkable experiments made in France seem fully to confirm the theory that the resistance of trains is rather a hyperbolic function of the speed, and at high speeds can be expressed by the equation of a straight line. In confirmation of this may be cited the tests of the well-known and eminent engineer of the state railways of France, M. Desdouit, the inventor of the pendulum apparatus for measuring acceleration. From exceedingly careful experiments made on the lines of the French state railways this engineer found that the resistance of the locomotive,

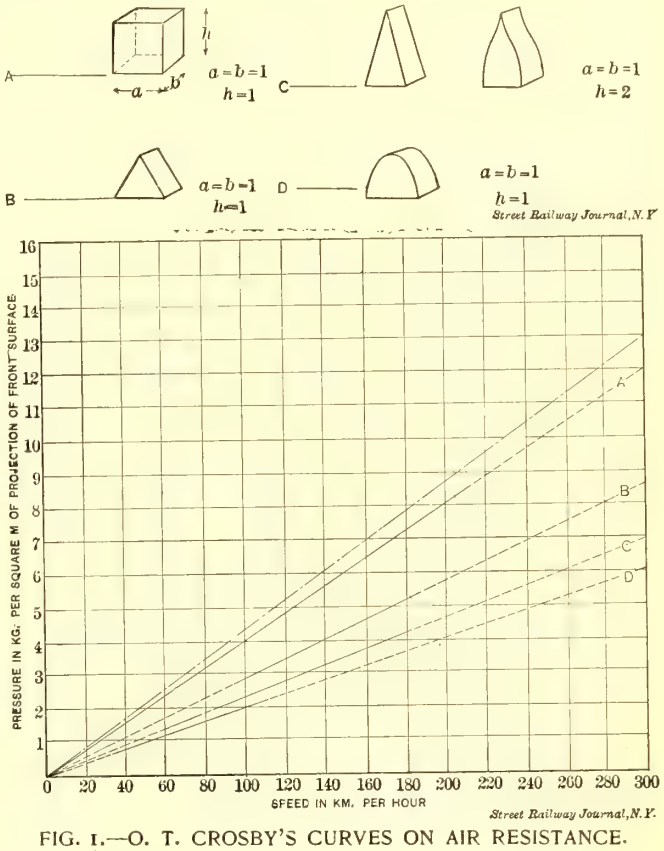

FIG. 1.—O. T. CROSBY'S CURVES ON AIR RESISTANCE.

with the tender, within the limits from starting up to 80 km., increased very nearly as a hyperbolic function of the speed of the form

$$R = a + \sqrt{b + cv^2}$$

The curve represented by this formula for a passenger locomotive weighing, with its tender, 55 tons (36 tons + 19 tons), and running with the steam shut off, is plotted as No. 1‡ in Fig. 2. As can be easily seen, at speeds higher than 40 km. the resistance increases very sensibly as a linear function of the speed.

On the same sheet is plotted another curve, No. 2, connecting three points, and also based on M. Desdouit's data. This curve seems to indicate that at high speeds the resistance of the locomotive increases with, but not so rapidly as, the speed. I do not consider this curve as improbable.

On the same sheet are plotted two curves, No. 3 S and No. 3 β, that are deduced from experiments made on the Paris-Lyons-Mediterranean line with new compound cylinder express locomotives by M. Privat, the engineer of that railway. These experiments were carried out by M. Privat in a very reliable manner, and were published partially in the "Revue Generale des Chemins de Fer" in 1896. In his very interesting article M. Privat discusses principally

* Given a certain number of points representing in an approximate manner (as is the case here) values of a function, as found by experiment, it is possible to plot many curves that will be more or less accurate within the small limits, but when extended will prove absolutely wr ong.

† See transactions of "American Institute of Electrical Engineers," February, 1891, and STREET RAILWAY JOURNAL, April, 1891.

‡ This curve represents the resistance on level track and in a perfectly calm atmosphere. M. Desdouit especially insists on the latter condition. The resistances expressed by the above curve include all elementary resistances due to vertical and horizontal shocks on the rails, friction of journals, friction of wheels on rails produced by the manner in which the wheels are fixed to the axle, side friction of flanges of wheels, resistance of the different parts of the mechanism, and finally, air resistance. Pneumatic effects of pistons in cylinders were practically eliminated by using such admission valves that the effect of vacuum due to the cut-off was practically nil; but all these resistances are considered by M. Desdouit to be small, as compared to air resistance.

the working of the compound system at different speeds, admissions in high and low pressure cylinders and the work performed. He plotted a series of curves showing the total amount of indicated power developed by the locomotive in hauling trains at various speeds and ratios of admission in the two cylinders. All these curves were reduced to the case of moving on a level and with no acceleration. Deducing the power required for hauling the train, he found curves showing the power required for moving the locomotive and tender alone, for the case of a level track and no acceleration.

I have plotted these curves in Fig. 3. The heavy lines here correspond to the case of an admission of 0.7, and the light lines to admissions of 0.4-0.5,in the *low* pressure cylinders. Numbers 0.2, 0.3, 0.4, 0.5 on both series of curves show ratios of admission, viz.: 0.2, 0.3, 0.4 and 0.5 in the *high* pressure cylinders. It is easy to see that the ratio of

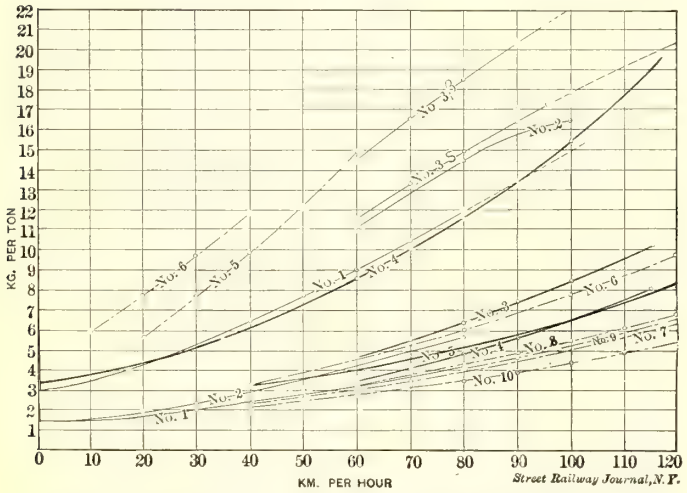

FIG. 2.—GROUP OF CURVES FOR RESISTANCE OF LOCOMOTIVES (WITH TENDER) AND FOR CARS ONLY.

Upper curves for locomotive and tender only.

Nos. 1 and 2.—Desdouit [French State Railways]. L = 55.

No. 3 β.—Maximum resistance deduced from M. Privat's experiments [French P. L. M. Ry]. L = 84.2.

No. 3 S.—Minimum resistance deduced from M. Privat's experiments [French P. L. M. Ry]. L = 84.2.

No. 4.—Barbier [French Northern Ry.] L = 93.5.

Nos 5 and 6.—Gen. Petroff.

Lower curves for cars only.

No. 1.—Desdouit [French State Railways] Q = 75, n = 8.
No. 2.— " " " " Q = 75, n = 3.
No. 3.—Barbier [French Northern Ry.] Q = 206, n = 15.
No. 4.— " " " " Q = 296, n = 7.
No. 5.—French Western Ry.
No. 6.—French Northern Ry., from Gen. Petroff's formula, Q = 206, n = 15.
No. 7.— " " " " " " Q = 206, n = 7.
No. 8.—Canadian Pacific " " " " " Q = 152, n = 5.
No. 9.—Pennsylvania Ry, " " " " Q = 162, n = 5.
No. 10.—Russian Railway, " " " " Q = 390, n = 13.

admission in the low pressure cylinders has a visible influence on the resistance of the locomotive.

Taking the mean of each group of light and heavy curves we obtain the probable average power required for moving the locomotive and tender under most favorable and most unfavorable conditions of resistance in functions of the speed. These mean curves are plotted in Fig. 4, and are slightly curved.

Without making a great mistake we can *a priori* assume them to be of the form

$$W = a + b\,v + c\,v^2$$

and find most probable values for a, b and c. Doing this we have very nearly

$$W_{min} = -40.2 + 1.64\,v + 0.0437\,v^2$$
$$W_{max} = -135 + 4.5\,v + 0.0375\,v^2$$

but only within the limits from 60 km. to 95 km.

Now if we put R as the resistance of the locomotive and tender (weighing 84.2 tons*) in kg. per ton of weight we shall have

$$W = \frac{R \times 84.2 \times v}{75 \times 3.6}\text{; whence}$$
$$R = \frac{3.2}{v} W$$

or, substituting values for W_{max} and W_{min}, we have

$$R_{min} = 5.24 + 0.14\,v - \frac{129}{v}$$
$$R_{max} = 14.38 + 0.12\,v - \frac{432}{v}$$

again only in limits from 60 km. to 95 km.

These two curves are shown by No. 3β and No. 3S in Fig. 2. While perhaps not being absolutely accurate, they

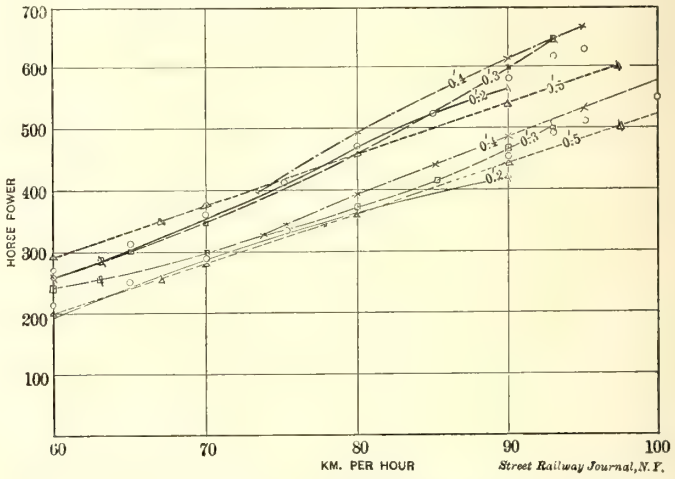

FIG. 3.—CURVES SHOWING POWER (NUMBER OF I.H.P.) REQUIRED FOR HAULING THE LOCOMOTIVE AND TENDER AT DIFFERENT RATES OF ADMISSION.

The lower curves show power required at most favorable ratio of admission, *i. e.* 0.7 in low pressure cylinders and the following ratios in high pressure cylinder.
———————— = 0.2.
———— ———— ———— = 0.3.
— . — . — . — = 0.4.
— — — — — — — — = 0.5.

The upper curves show power required at unfavorable ratio of admission *i. e.* 0.4 to 0.5 in low pressure cylinder and the following ratios in high pressure cylinder.
———————— = 0.2.
———— ———— ———— = 0.3.
— . — . — . — = 0.4.
— — — — — — — — = 0.5.

can be considered characteristic and in a certain accord with M. Desdouit's opinion. Of course, between these two limiting curves we could plot a multitude of others, more or less inclined, depending on the ratios of admission in the high and low pressure cylinders. But in the case of the continuous use of an admission of 0.7 in the low pressure cylinders we have the limiting curve No. 3S, that seems to indicate that the resistance of the trial locomotive, when well governed, increases rather more slowly than the speed, or, at least, very nearly as a linear function of the speed, again within limits from 60 km. to 95-100 km.

In the same diagram is plotted the curve, No. 4, found by M. Barbier during a very extended set of experiments made recently on the French Northern Railway with two new, fine four-cylinder compound express locomotives, designed by M. Du Bousquet. A very complete report of these tests, made by M. Barbier, appeared in a series of articles published by the "Revue Generale des Chemins de Fer" in 1897-1898. The curve No. 4, which is taken from this paper, has a slightly parabolic form.

$$R = a + b\,v + c\,v^2$$

The very low resistances given by this curve are due largely to the fact that the weight of the tender was considerable (43 tons) as compared to that of the locomotive (50 tons).**

Also in Fig. 2 are plotted two curves, Nos. 5 and 6,

* By "tons" in this article, the metric ton = 2200 lbs., is intended.

** The writer is not disposed to criticise in any way M. Barbier's very complete and reliable experiments and deductions, but may not a curve of a hyperbolic form, if taken a *priori*, instead of a parabolic one, prove no less accurate and concordant with the series of points found by experiment?

given by General Petroff, now Assistant Minister of Ways of Communication. Both are represented by the parabolic equation

$$R = a + b\,v + c\,v^2$$

Curve No. 6 represents the resistance of a freight locomotive, and No. 5 that of a passenger locomotive. The points for these curves were established at comparatively small speeds. For high speeds they give too large results, and General Petroff himself admits that in the case of the curve No. 5 at speeds from 80 km. to 100 km. the resistances given by this curve must be reduced by about 20 per cent.

All these considerations seem to strengthen the opinion that at high speeds the resistance of the locomotive increases very nearly with the speed. The latest experiments on air resistance seem to prove that this factor increases as the first degree of speed, and air resistance is the largest part of the total resistance of the locomotive. On the other hand, the friction in journals diminishes at high speed, because of a better oiling, but as the coefficient of friction is very small,* it need not be taken into account when considering the resistance of locomotives.

Before passing to the resistance of trains of cars and of complete trains the writer thinks it may be interesting to point out a well-known way, if adopted in the right manner, of lessening the resistance of air to the motion of the locomotive.

Some years ago shields for reducing the air resistance were tried on the Paris-Lyons-Mediterranean Railway. These shields were of about the same size and shape as an ordinary nose snow plow, but were carried higher on the locomotive, partly hiding the stack. It was found, however, that the useful effect of these shields in reducing air resistance was not considerable, and they were abandoned. Such an arrangement lessened the front pressure, but as it was open at the back, it had as an effect the forming of a vacuum at the rear of the shield with consequent eddy currents, increasing the resistance. If completed to the back part of the locomotive the shield would have proved far more efficient. Experiments made on the French Western Railway with the first Heilmann electrical locomotive in 1894 seem to confirm this opinion.

RESISTANCE OF THE CARS FOLLOWING THE LOCOMOTIVE

The resistance of the cars only of a train, that is, the total resistance of the train minus that of the locomotive, is plotted in the lower series of curves in Fig. 2. It will be remembered that the resistance curve of a locomotive is generally of a hyperbolic form, and in some cases the curve is concave on the axis of X (such as shown from M. Privat's test). On the other hand, almost all curves for resistance of the cars are of a well-marked parabolic form. These latter curves seem to be reliable, as the resistance of the cars can be measured accurately by means of a dynamometric car, and consequently the values can be found more accurately than that of the resistance of the locomotive alone or of the complete train.

It is easy to see from a glance at Fig. 2 that these curves for car resistance do not coincide in shape. This is caused by the fact that the respective importance of each of the different factors which make up the resistance varies with the number of cars in the train, the distances between the cars, the load on each axle, and the number of axles per car, as well as within certain limits with the conditions of track, weight of rails, size and number of ties. The influence of the latter factor can be appreciated by considering that the effect of the forward wheels upon an elastic track is to produce a continuous wave immediately in front of the wheels. This factor, of course, affects the resistance of the locomotive more than that of the cars, on account of its greater weight. Most of the existing formulæ do not include all of these various factors.

In the lower series of curves plotted in Fig. 2, Nos. 1 and 2 are those of M. Desdouit. Both of these are for a train weighing 75 tons, the first for a train of eight four-wheel cars, and the second for a train of three eight-wheel cars. It is easy to see that the second curve shows a lower resistance. This is due mainly to the fact that the number of spaces between the cars is less, and, therefore, that the resistance of the air in the shape of eddy currents and partial pressures on the fronts of the cars is less, there being fewer car fronts. It is also due, however, to the fact that the running was smoother with bogie trucks, horizontal shocks on the rails being fewer and

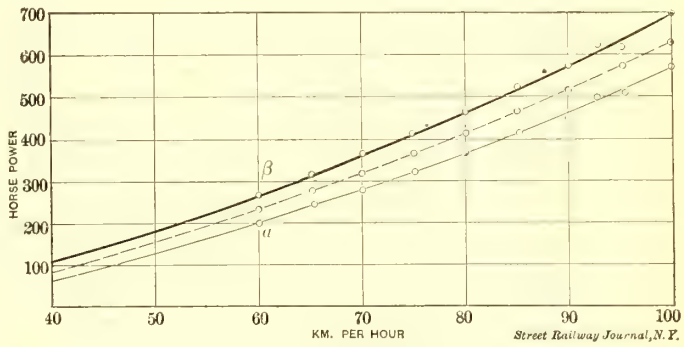

FIG. 4.—MEAN OF CURVES SHOWN IN FIG. 3.

(β) Mean of upper curves shown in Fig. 3.
(α) " " lower " " " Fig. 3.
" " α and β

smaller. So far as the first factor is concerned, a vestibuled arrangement between the cars would have reduced the resistance; and so far as the second factor is concerned, it is needless to say that every side shock involves a loss of energy in the form of *vis viva*.

So far as the friction of the journals is concerned, there is practically no difference, whether the cars are mounted on bogies or on two axles, like a single-truck electric car, or some of the freight cars in Europe, since, as has been already stated, the coefficient of journal friction is very small (only about 0.005). This disposes, by the way, of the question of roller bearings on cars, showing that they have no value from a practical standpoint.

Curves Nos. 3 and 4 are due to M. Barbier, and are the result of very extensive tests made by him several years ago on the French Northern Railway.* Here, again, the influence of the trucks and number of cars is very marked; curve 3 corresponding to a train of fifteen four-wheel cars, and curve 4 to a train formed by seven eight-wheel cars mounted on bogie trucks. The weight was the same in both cases, *i. e.*, 206 tons. Curve No. 5 was found in 1897 by a test of trains made up of four-wheel cars running on the French Western Railway. All of these five curves do not differ materially from each other. Finally, curves Nos. 6, 7, 8, 9 and 10 were plotted from a formula suggested by General Petroff.

While most of the other formulæ are of the shape

$$R = a + bv + cv^2$$

and therefore can be applied only in cases similar to those for which the constants a, b and c were established, General Petroff's formula for *resistance of cars only* is

$$R = 1.2 + \frac{0.6n}{Q}v + \frac{0.03}{Q}(1 + 0.004n)\,v^2$$

where

* The coefficient of friction is generally taken = 0.05, but General Petroff considers 0.005 a closer valuation.

* See "Revue Générale des Chemins de Fer," 1897.

R = resistance in kg. per ton (metric) of train (cars only)
Q = weight of the train (cars only) in tons (metric)
n = number of cars
v = speed in km. per hour.

This formula was found by means of a very careful and scientific study of *all* the causes for resistance, and as the air resistance is not so large a factor in the total resistance of the cars of a train as it is in the resistance of a locomotive running independently, this formula gives much closer results for all cases than the Petroff formula for the resistance of a locomotive. This latter, as has been previously stated, is not quite correct, because of the narrow limits of speed between which the tests were made, and because of the false assumption that Newton's formula for air resistance, *i. e.*, $R = k S v^2$, is correct.

Having once established the general form of his equation for the resistance of cars, General Petroff found the most probable values of coefficients from a very large number of experimental data. Curves Nos. 6 and 7 in Fig. 2 correspond to the case of a train on the French Northern Railway, such as used by M. Barbier's experiments. The weight of the train (cars only) in both cases was 206 tons, number of cars, fifteen for curve No. 6, and seven for curve No. 7. It is easy to see General Petroff's formula gives results somewhat lower than those found by M. Barbier. Curve No. 8 corresponds to a train on the Canadian Pacific Railway, weighing 152 tons, and composed of five cars. Curve No. 9 shows the resistance of a train on the Pennsylvania Railroad, weighing 162 tons, and composed of five cars. Curve No. 10 is that of a train on the Russian Nicolaievski Railway, running from St. Petersburg to Moscow. This train weighs (cars only) about 390 tons, and the number of cars was thirteen.

RESISTANCE OF COMPLETE TRAIN, INCLUDING LOCOMOTIVE, TENDER AND CARS

Finally, in Fig. 5, I have plotted some curves showing resistances of complete train, including locomotive, tender and cars. In plotting these curves the maximum and minimum resistances of the locomotive and tender are taken from the maximum and minimum values as given in curves No. 3β and 3S in Fig. 2, as found from M. Privat's experiments. For the resistance of cars General Petroff's formula is used. The two values are then combined by the following formula:

$$R_m = \frac{R_{loc} \times L + R_t \times Q}{L + Q}$$

in which
R_m = resistance of total train in kg. per ton
R_{loc} = resistance of locomotive and tender in kg. per ton
R_t = resistance of train (cars only) in kg. per ton
L = weight of locomotive and tender in tons
Q = weight of train (cars only) in tons.

Thus, in Fig. 5 curves Nos. 1 and 2 correspond to the case of the train used in the experiments made by M. Barbier, in which L = 93 tons, Q = 206 tons, n = 7; in the upper curve the formula for the maximum resistance of the locomotive is used, and in the lower one the minimum. The two curves No. 1′ and No. 2′, lying quite close to curves Nos. 1 and 2, correspond to the case of a train on which experiments were made on the Austrian Ferdinand Northern Railway. Here L = 96 tons, Q = 203 tons, n = 5. Curves Nos. 3 and 4 correspond with a train on the Pennsylvania Railroad; L = 82 tons, Q = 162 tons, n = 5. Curves Nos. 5 and 6 correspond with a train on Russian Nicolaievski Railway. L = 91 tons, Q = 390 tons, n = 13.

As will be seen, within the limit of speed from 60 km. up to 120 km., all these curves are practically straight lines. Finally, curves S and V represent, respectively, the resistances of trains as found by Mr. Sinclair, and quite recently by Mr. Vauclain, of the Baldwin Locomotive Works. Mr. Sinclair's formula, expressed in kg., tons metric and km., is R = 1 + 0.075 v. That of Mr. Vauclain, expressed in kg., tons metric, and km., is R = 1.5 + 0.052 v. These last two formulæ give for resistance of trains (locomotive and tender included) straight lines too, with limits from 50—60 km. up to 120 km. (*)

Having all these curves before us, it seems interesting to see how they agree with data found directly from experiments.

(1) On the Russian Nicolaievski Railway it was found

that new high-speed locomotives, weighing, with tender, 91 tons, were capable of hauling continuously trains of 390 tons at a uniform speed of 80 km. on the level, and of 48 km. on a 0.8 per cent grade. From curve No. 5 we learn that the locomotive was obliged to develop about 915 i.h.p. in the first case, and 860 i.h.p. in the second. These data do not differ materially. As the locomotive was designed for high speeds it was naturally able to develop more power when running at 80 km. than at 48 km.

(2) On the Austrian Ferdinand Northern Railway a locomotive weighing, with tender, 96 tons, when running with a train of 203 tons on a grade of 0.26 per cent at a uniform speed of 80 km. developed about 1027 i.h.p. From curves Nos. 1′ and 2′ we obtain, respectively, maximum power, 1000 i.h.p., and minimum power, 890 i.h.p.

(3) On the Pennsylvania Railroad a locomotive weighing, with tender, 82.5 tons, when running with a train of 162 tons on a level at a uniform speed of 104 km., developed about 1120 i.h.p. From curves Nos. 3 and 4 we obtain respectively, maximum power, 1080 i.h.p., and minimum power, 945 i.h.p.

The writer has at his disposal too small a quantity of similar data to carry this investigation further, but it would be of interest if persons who have made tests of this kind should try and combine, in the manner shown above, the

* A final reason for a lower coefficient of resistance at high speeds can be found in a reduced coefficient of track resistance due to a better alignment of the cars on the track. This can be deduced analagously from some experiments conducted by M. Barbier on the French Northern Railway on the resistance of trains on grades. If the track resistance were the same on level tracks and grades, it would be natural to assume an increase of 1 kg. per ton for every 0.1 per cent of ascending grade and a decrease of 1 kg. per ton for the same per cent of descending grade. The tests made showed, however, that the increase when ascending was only 0.9 kg., instead of 1.0 kg., and the reduction on the descending grade was 0.9 kg., instead of 1.0 kg. This difference in the case of the ascending grade is attributed to the greater tension of the train, by which the axles are kept more closely at right angles with the rails. As a result, there is less flange wear, and the track friction is reduced to a minimum. Conversely, the increase in resistance on down grade is due to a relaxation of the tension, permitting the cars to get out of alignment, increasing the wheel and track resistance.

curves for resistance of locomotive and tender, as found from M. Privat's experiments, and those of General Petroff for the resistance of trains (cars only), finding thus a curve for the resistance of a complete train, including locomotive, tender and cars in different cases, and obtaining the i.h.p. of the locomotive as developed from the formula

$$W = \frac{R_m \times (L+Q) \times v}{75}$$

R_m = resistance in kg. per ton of complete train
L = weight of locomotive and tender in tons
Q = weight of cars in tons
v = speed in meters per second
W = work in i.h.p.

It would be interesting to learn how these values accord with the values of the i.h.p. as obtained directly by indicator diagrams.

While a little outside of the subject of discussion, the writer suggests that the portion of the air resistance which is made up through the creation of a partial vacuum and consequent eddy currents at the rear of the train, a factor which constitutes a certain amount of the total air resistance, could be lessened in a measure, which might be considerable, by placing at the end of the train a car formed somewhat like the inverted stern of a boat, as shown in Fig. 6. It is a well-known fact that the resistance of a

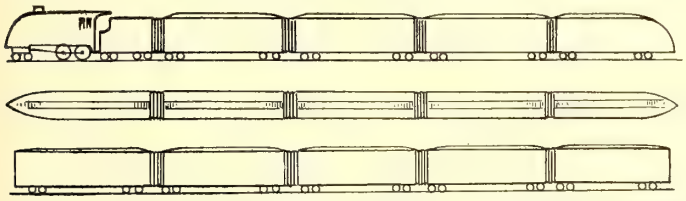

FIG. 6.—PROPOSED FORMS OF ELECTRIC AND STEAM TRAIN FOR REDUCING AIR RESISTANCE.

ship moving at high speeds depends very much upon the form of the stern, even more than upon the form of the bow. If the stern of the vessel is not sufficiently acute, there is a tendency to create a vacuum, and considerable power is lost in eddy currents, and when the train is moving rapidly it is natural to suppose that there is a corresponding depression behind the last car. The writer has no data as to the amount of power that is lost in this way, but it is possible that experiments in that direction will prove interesting and valuable. For high speeds, then, he would suggest trains of vestibuled cars with, in case of an electric train, a pointed motor car and rear car, and with a steam train, a complete protective shield on the locomotive to form a cutting surface.

The Expenses of Mechanical Traction in Paris

The annual report of the Compagnie Générale des Omnibus, the largest street railway company in Paris, has just been published, and from advance proofs the STREET RAILWAY JOURNAL is able to show some of the results secured in operating costs by the different systems of mechanical power employed. The company has four types of mechanical motors, viz.: Serpollet locomotives, Rowan locomotives, compressed air locomotives and compressed air motor cars. The locomotives draw two or three trail cars and the motor cars one trail car. The car mileage made by the different systems last year was as follows: Serpollet motors, 902,968; compressed air motor cars, 640,375; compressed air locomotives, 546,198; Rowan locomotives, 117,685. To these should be added the mileage made on one line (Louvre-St. Cloud) of 354,297, made up of a mixed service of Rowan and compressed air locomotives.

The cost of operation of all the mechanical systems is given below in francs per car km., cents per car mile and gross expenses in francs. The cost of the operation of compressed air motor cars drawing one trail car amounted in 1898 to 0.4815 francs per car km. (15.07 cents per car mile), and for compressed air locomotives capable of drawing several trail cars, 0.5358 per car km. (16.76 cents per car mile). The company is probably the largest tramway company in Europe, and is one of the largest in the world. It operates both tramcars and omnibuses, and in its tramway department alone the operating expenses (including taxes) amounted in 1898 to about $3,400,000, and, including the omnibus service, the operating expenses of the company were over $8,000,000.

Following the table of expenses for mechanical power are given those for horses, so that a comparison of the operating conditions in Paris may be drawn. In this table a franc is considered equal to 19.45 cents, and a kilometer equal to 0.621 miles. The fractional differences account for the difference of one figure in the last decimal place in some cases.

Mr. Sprague on Rapid Transit in New York

The following letter has recently been written by Mr. Frank J. Sprague, to Chairman Orr, of the New York Rapid Transit Commission:

Sprague Electric Company,
New York, April 26, 1899.

Dear Sir—I have read with interest the letter of March 29, 1899, addressed to you by President Stuyvesant Fish, of the Illinois Central Railroad.

Coming from the chief officer of a railroad which has accomplished so much in the way of steam rapid suburban service, its conclusions should, and naturally will, receive serious consideration.

With many of the facts stated and with some of the views promulgated, especially those suggesting guaranteed high schedules, I am in hearty accord, but there are two statements which I will quote *in extenso*, which are in error, or are capable of two readings. These are:

Paragraph I. "The motive power used by the Illinois Central consists of steam locomotive engines, most of which were built many years ago. If the tunnel company is to be tied down to electricity as a power it cannot, in the present state of the science, be required to make the speed of our trains. We believe, however, that before long it may become possible to move trains by electricity on our schedules, and we have been carefully watching developments in that direction for many years."

Paragraph IV. "As yet electricity has not been applied in such a way as to give a service equal in speed to that furnished by the Illinois Central in Chicago by using steam. After the most careful, painstaking and patient investigation, we have been forced to adhere to the use of steam, although anxious on many accounts to substitute electricity. . . . While I believe that electricity can be hereafter so used as to develop schedules about equal to those which we now have in use in Chicago, there is as yet nothing to show that better can ever be done through the use of electricity. Our investigations teach us that with each added unit of speed the cost increases more rapidly where electricity is used than where steam is used."

It is impossible to understand the reason for the conclusions given by Mr. Fish, and I must take exception to them, not only from engineering reasons, but from the record of accomplished facts.

Under any given conditions schedule speed is solely a question of the amount of available power per ton and the proportion of it which can be effectually used. The higher the schedule, the shorter the station intervals and the longer the station stops, the greater will be the amount of power required for moving any given tonnage, and the greater the power thus required, the higher the ratio of weight moved which must be on the driving wheels.

On the local suburban service of the Illinois Central Railroad a five-car train weighing, with its passengers, 105 tons, is driven by a locomotive of 80 tons weight, which can develop from 900 to 1000 effective brake h.p., making the total weight moved 185 tons, 46 of which, that is, 25 per cent, are on the drivers. Or, to epitomize, there is provided a maximum of about 5 h.p. per ton, with 25 per cent of weight moved on the drivers.

Leaving, for the moment, out of all consideration *how* it is to be done, if greater power is applied to a train and a higher percentage portion of the weight on the drivers is utilized during the period of acceleration, higher schedules immediately become possible.

Taking the street railway systems of the country as a precedent, from 80 per cent to 100 per cent, not 25 per cent, of the weight is on the drivers. Adhering to the single car as a unit, and putting all the available power in the motors connected to each of its axles which space permits, it is readily possible to put on motor equipments which will develop not less than 20 h.p. to 22 h.p. per ton moved, and to use 100 per cent of the weight on the drivers. The possibilities of this unit, that is, using the entire weight of a car for traction, and all the power which can be put within the space provided, *is the limit, and absolutely the only limit*, of the possibilities of speed to be attained by an electric car, and it must necessarily exceed that possible to a steam locomotive alone.

Lengthen now this unit, put joints in; that is, aggregate cars into a train, preserve the same ratio of weight on the drivers and the same h.p. per ton, then it matters not what the length of the unit; in other words, no matter what the size of the train, identically the same schedules can be made with a train as with a single car.

In the table of Illinois suburban trains, the local schedules are stated as 18.51 and 18.76 miles an hour, with stations averaging 2900 ft. apart.

On Dec. 23, 1897, a proposition was made to the Illinois Central Railroad by the Sprague Company, which required the use of the entire weight of cars and a very high power equipment, and guaranteed a schedule of 24½ miles an hour on the same runs, but it was not accepted at the time, and I think wisely, in view of the developments which were being undertaken on another road, namely, the South Side Elevated of Chicago, and the opportunity which these would afford for study and natural improvement. This latter road has been in operation for nearly a year. It started with an original equipment of 120 cars, each of which was equipped with two 50-h.p. (hour rating) motors on one truck, or a maximum of about 6 h.p. to 6½ h.p. per ton with average loads, and utilizing from 60 to 62 per cent of the total weight on the drivers, the general equipment being what is known as the Sprague "multiple unit" system, in which each equipped car is a self-contained transportation unit, but so controlled that aggregations in any number or sequence can be made, and the whole controlled from a single point. For weeks, every day, morning and night, with the exception of Sundays, 119 out of 120 equipped cars, pulling 28 or 29 trail cars, thus overloading the general equipment one-third, has run on as hard service as has ever been undertaken on any elevated railroad, and the success of the system from every standpoint has been unparalleled in so novel a departure. This equipment has been followed by thirty more completely equipped cars.

It may be that Mr. Fish referred to this system in speaking of the possibilities of the future, and the limitations spoken of were as to schedule speeds actually accomplished, rather than to methods demonstrated. On the South Side road no attempt was made to equal the schedule of the Illinois Central Railroad. The contract requirement was 15 miles an hour, with existing station intervals, and 16½ miles have been frequently made, but if a higher schedule had been desired all that was necessary to be provided was more power. The general method of application and control is settled for a finality.

It is true that as the schedule increases, the power increases in a more rapid ratio, and equally true whether the power is steam or electricity, but cars equipped and controlled on the system referred to here are already in operation, and taken singly or aggregated into train units, will outrun any possible steam combination which now exists on the local suburban service of the Illinois Central, or any other road, and this fact can be easily demonstrated in this city with existing equipments, so far as permitted by local conditions.

As I have stated, much in the letter meets my hearty assent, but the inferential conclusion that a four-track elevated railroad, however good an engineering proposition in itself, is advisable, because steam can be used on it, whereas electricity only can be used on an underground, is untenable.

A number of years have passed since I publicly offered, at my own expense, to run express trains at 40 miles an hour on an elevated structure in this city with electricity as a motive power, and I am ready to guarantee, in competition with any other known method of train operation, whether for local or express service, practical schedules higher than have ever yet been attempted, and higher than is possible by any combination, steam, air, or electric, which localizes the power in one or two units, and pulls dead cars between or behind them.

It may be pointed out that the actual limit of schedule speed possible on a level railroad, with stations averaged at 2900 ft., as on the Illinois suburban, and with a maximum of 300 lbs. to the ton adhesion, is very nearly 30 miles per hour, as against 18.51 and 18.76 given in Mr. Fish's reference, and these increased schedules are absolutely only possible with electric motor application, and where the motors are distributed throughout the train, every pair of wheels being used as drivers. Of course, this is in fact the aggregation of the car units, such as fill our city streets, except somewhat larger in size, with the addition of a suitable secondary control, which simutaneously governs all cars.

In this connection permit me to call attention to a letter, under date of April 1, 1898, to Mr. John H. Starin, the then chairman of your contract committee, copy of which I inclose herewith. Very respectfully,

FRANK J. SPRAGUE,
Second Vice-president and Technical Director.

LETTER TO MR. STARIN

John H. Starin, Esq.,
Chairman Contract Committee, Rapid Transit Commission,
22 William Street, New York.

APRIL 1, 1898.

Dear Sir—In all the published accounts on the subject of the negotiations between the commission and the Manhattan Elevated Company, as well as with any one else, one of the most important essentials seems to be entirely ignored. Routes, structures, rights of way and penalties are all considered, but the one thing which would do more to relieve congestion does not seem to be insisted upon, and that is the question of motive power.

The time has past when there could be any question as to the advisability of abandoning steam and adopting electricity, and by this agent, and this alone, can the essentials of cleanliness, reduction of noise, smoothness of operation, and, what is most important of all, increase of schedule speed, be obtained.

The elevated railroads now make on way trains a schedule speed of not exceeding 12 miles an hour, including stops, when running with loaded trains. It is possible to increase this to 18 or about 18½ miles, although that is the absolute maximum with station stops as they now exist; but 16½ miles is within the range of practical, reasonable demand.

It would seem, therefore, perfectly proper that the following conditions should be introduced in the granting of any franchise, of any kind whatsoever, and to whatsoever company:

1. That there shall be a change from steam to electricity.
2. That there shall be a schedule speed, including stops at each station, of not less than 16½ miles, whatever the length of train.
3. That there shall be a schedule speed, including stops at limited stations, of express trains of not less than 30 miles an hour.

The above conditions can be met, and it is only reasonable to expect that these increased speeds should be supplied by the railway company if they receive additional privileges.

Very truly yours,
(Signed) FRANK J. SPRAGUE.

The City Council of Bergen (Norway) has refused the proposition to buy and operate the local street railway system.

The Destruction of Old Transfers and Tickets

After transfers and tickets have been used the chief object of the railway company is to so destroy them that they can never be employed again. The usual practice is to have the tickets burned under the oversight of some responsible officer of the company, but this is not the only method employed. The STREET RAILWAY JOURNAL recently made an investigation of the methods in use by a number of companies in this country, and obtained the following particulars as to the practice of a number of companies in destroying tickets.

On the Brooklyn Heights Railroad Company the tickets are chopped in a machine designed for that purpose, and when thus mutilated are sold as waste paper. The company tried burning the tickets under the boilers of one of its power stations, but was obliged to transport the tickets to the power station, which was a considerable distance from the office, and after a short experience found that this was not the safest way of disposing of them.

The Boston Elevated Railway Company has for several years used a ticket cutting machine, located in the office of the auditor of the company and operated by a 1-h.p. motor. The machine was originally built to run by hand, but was altered in such a way that electric power could be used. With this machine the company is able to destroy about three barrels of tickets in two hours. The refuse is sold for a small amount.

The Twin City Rapid Transit Company, of Minneapolis, Minn., has for some time burned all of its canceled tickets under one of the large boilers connected with the general office of the company. This method, however, is not regarded with very great satisfaction, and the company may install a machine similar to that used in Boston and mentioned above.

The North Jersey Street Railway Company, of Jersey City, N. J., disposes of its tickets and transfers by burning them at one of its power stations. The tickets and transfers are in the custody of the cashier, who personally supervises the disposal of them from the time they leave the office until they are consumed in the furnace. Owing to the large number of lines operated, the company has a great many tickets and transfers, and finds that this is the best way to dispose of them.

The Milwaukee Electric Railway & Light Company writes that the practice of that company is to tie the tickets up daily in large paper sacks and then to burn them, a clerk from the accounting department supervising the operation.

The Metropolitan Street Railway Company, of New York, adopts a similar method, except that the tickets are first chopped into very small pieces before being burned.

The New Orleans Traction Company also employs the method of burning its old tickets. The plan has been found very satisfactory.

The Third Avenue Railroad Company, of New York, adopts a similar method, the tickets being deposited in wooden boxes before being taken to the boiler room.

The Union Traction Company, of Philadelphia, Pa., also destroys its tickets by throwing them into the furnace of a boiler room adjacent to the receiver's office. The tickets, however, are first placed in a manila paper bag 33½ ins. long and 11 ins. wide. The operation is conducted in the presence of the receiver, who witnesses their complete destruction.

The United Traction Company, of Pittsburgh, Pa., employs the same method, but keeps the tickets for a short time, usually a few weeks, before burning them in the power-house furnace.

On the Market Street Railway, in San Francisco, the tickets are returned to the accounting office, where they are inspected and checked, and are then deposited in a chute, which conveys them to a locked receptacle in the basement. This receptacle is opened daily after office hours and the tickets, transfers, etc., are emptied into a box truck, wheeled to the engine room and shoveled into the furnace. This is done under official supervision, although there is little opportunity of reusing the tickets, as the transfers are not only stamped with the date, month and year, but are also canceled at the time of being received for fare.

A Steam vs. Electric Rate War in Missouri

Fred H. Fitch, formerly of the Chicago City Railway Company, but more recently interested in the Southwest Missouri Electric Railway, and who is now again located in Chicago, was in New York last month, and gave some interesting particulars of a rate war which occurred when he was connected with the Southwest Missouri Electric Railway. This railway, which is described elsewhere in this issue, connects the important towns of Carthage, Carterville, Webb City and Joplin, Mo., and Galena, Kan.

Previous to 1893 all travel between these centers of population was taken care of by the steam railways, the charge being 3 cents per mile, and trains were run at very infrequent and irregular intervals. The district demanded more frequent and cheaper service, and in 1893 the electric road made its appearance, and by 1896 communication from Carthage through to Galena was had every half hour for eighteen hours during the day, at a cost of about 1 cent per mile. The district felt the healthful effect of it; the people and the press praised the men who had made it possible, and the road prospered.

The St. Louis & San Francisco Railroad Company, familiarly known as the "Frisco," in June, 1897, put on in competition with the electric road an interurban service, running trains consisting of an engine, combination baggage and smoker, and a coach, every hour over one portion of its road, and every two hours over another portion. The steam fares were reduced to meet those of the electric road, and the running time was about two-thirds that required by the electric cars. In order to discount the advantage which the electric road had in running through the streets, the steam railroad managers inaugurated a free hack service between the business portions of the towns and their depots.

In June, 1898, the electric railway company succeeded in obtaining a franchise into the city of Galena, and the "Frisco" managers immediately notified the electric railway company that unless it disavowed all intention of extending its road under the grant obtained that they would cut the rate to 5 cents between any two adjacent towns, and make 10 cents the maximum rate anywhere along the line. This threat was put into execution in June, and meant a cut from 40 and 25 cents to 10 cents, and from 10 cents to 5 cents.

But the "Frisco" did not stop here. For a while, on Sundays and holidays, this new rate was cut in two, and a rate of 10 cents only was charged for the round trip from Carthage to Galena and return, and correspondingly low rates along the line. This made a ride of 60 miles for 10 cents, or 1/6 of a cent per mile. Here is what the lucky populace could do on these occasions: enter a hack at a hotel in Carthage and be taken to the depot; be transported to Galena, 30 miles; enter another hack, and go to a hotel or to the business center; having spent the day in Galena, be driven to the depot, take a train for Carthage, and there take a hack to their homes, all for the great sum of 10 cents.

Mr. Fitch quoted from W. F. Merrill, second vice-president of the Erie Railroad, who said before the New York Railroad Club that it costs the Erie 27 cents per mile to run a train similar to those run by the "Frisco," "and," he added, "while Mr. Merrill didn't say as much, I don't believe the 27 cents included any expense for operating free hacks." Meanwhile, the receipts of the "Frisco" were from 12 cents to 15 cents per train-mile, and they operated 600 miles per day.

On Jan. 8 last an agreement was reached and the rates were restored, although not to the original amounts, for one lesson learned from the rate war was that cheap fares make business, and that an error can be made in making rates too high.

The "Frisco" still maintains its interurban train service, but the electric road is doing a splendid business, greater than ever before, and, having safely and victoriously passed through the bitterest fight that it can probably be the misfortune, or fortune, perhaps, of an interurban electric road to encounter, it no longer looks upon the "Frisco" as a bugaboo.

Southwestern Gas, Electric and Street Railway Association

In consequence of a smallpox epidemic at Laredo, the annual convention of the Southwestern Gas, Electric and Street Railway Association, which was to have occurred on April 19, 20 and 21 at Austin, has been postponed until May 17, 18 and 19. Advantage will be taken of the postponement to elaborate the plans for the meeting, and also for the electrical exhibition to be held in connection with the convention. The exhibition will be held in a well-arranged building, 80 ft. x 120 ft., which is situated near the railroad tracks, and is easily accessible from all parts of the city. The meeting and exhibition promises to be one of the most successful of its kind ever held. The following is a list of the papers which will be presented and discussed at the convention:

"The Item of Depreciation," by W. E. Hamilton, Shreveport, La.

"Meters," by W. E. Holmes, Austin, Tex.

"Transformers," by Harry L. Monroe, Dallas, Tex.

"The Amount and Extent of Legitimate Investment in Electric Lighting Plants of Certain Capacities," by F. Fries, San Antonio, Tex.

"Summer Amusements for Street Railway Companies," by W. H. Steuart, Waco, Tex.

"Art and Science of Selling Gas," by Thomas D. Miller, Dallas, Tex

"A Model Plant Under Model Management; What Both Would Be Like," by J. F. Strickland, Waxahachie, Tex.

"Alternators," by E. Dysterud, Monterey, Mexico.

"The Attitude of a Corporation to the Public," by W. R. Weiss, San Antonio, Tex.

"Means of Encouraging the Diversified Use of Electric Current," by C. L. Wakefield, Dallas, Tex.

Mexican Paper—"Electric Lighting and Application of Electricity to Various Purposes in Mexico," by a Mexican delegate.

"Arc Lamps," by Max Levy, Galveston, Tex.

"Fare Boxes vs. Conductors," by F. E. Scovill, Austin, Tex.

"Transfers," to be assigned.

"Gas for Fuel," to be assigned.

Some Recent Street Railway Parks

LAKESIDE PARK, MO.

The Southwest Missouri Electric Railway Company, with headquarters at Webb City, Mo., operates about 34 miles of track, extending from Carthage, Mo., to Galena, Kan., and passing through a number of towns and villages in its course. Along the line are situated two or three beautiful pleasure resorts, which are well patronized by the population of nearby towns, particularly of Joplin and Webb City. The most extensive of these parks is known as Lakeside, and is situated 7½ miles from Carthage, 3 miles from Webb City, 9 miles from Joplin, and 15 miles from Galena.

It is truly one of nature's parks, being located on the banks of a pretty stream of water, and containing a large and beautiful lake. The park has an abundance of forest trees, making a most delightful shade. As the lake is large and deep, one of the principal attractions is, of course, the boating, a large number of pretty boats of all descriptions being kept in readiness at all times for visitors. Bathing is another of the principal features of this resort. A floating bath house, especially for ladies and their escorts, equipped with all the modern accommodations, such as bathing suits and other necessities, is provided, in addition to a gentlemen's bath house, which is equipped with springboards, swinging ropes, etc. To amuse and entertain the children and young people a large number of swings have been distributed throughout the park.

One of the best appreciated features of Lakeside is the abundance of pure, cold water, there being two 160-ft. wells, that are never-failing, and the quality of the water is equal to the spring water at many of the popular watering resorts.

The grand pavilion, which is shown herewith, is a handsome and costly structure, with a stage and new scenery, and a seating capacity of 1000. It is built without sides, but is provided with curtains around its entire length, so that in case of rain it can be closed in a moment, making it a large and commodious hall. In this pavilion, and also throughout the park, are large tables and seats for picnic parties, etc. At one end of the pavilion are comfortable dressing rooms for ladies and gentlemen, and nothing is lacking in the way of accommodations to visitors. Not less pleasing than the charming scenery and delightful attractions at the park is the enjoyable trip from either direction. The country through which the road passes is one of the finest in the West, and the road itself is one of the best constructed and equipped properties in the United States.

HIAWATHA PARK, OHIO

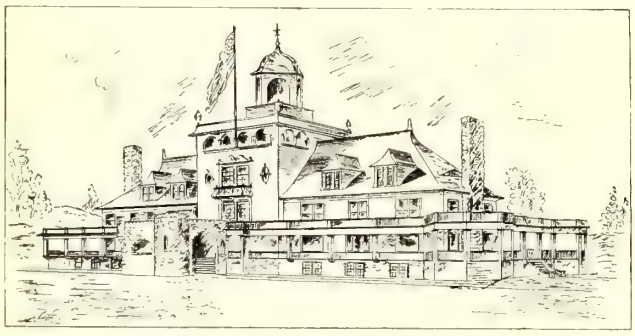
The owners of Hiawatha Park are busily engaged getting the place into shape for the opening exercises, which will occur on Decoration Day. This resort is on the line of the Mt. Vernon Electric Railway Company, of Mt. Vernon, Ohio, and is conspicuous for its pleasing scenery and for the diversity and attractiveness of the amusements that are provided. Three years ago P. B. Chase, president and general manager of the Mt. Vernon Electric Railway Company, took charge of the old county fair grounds, which had not been used for years, and which consisted of a rough, unkept plot of ground with dilapidated buildings and fences. As a result of his planning and energy, this place has been transformed into a beautiful park, and when the changes now under way are fully carried out, this spot will be an ideal pleasure resort.

The fountain is being rebuilt and enlarged, the material used being moss-covered stone. The flower vases have been replaced with large rustic ones of the same material as the fountain, and these will contain growing plants. The floral work about the park will this year be finer and much more extensive than in other years, and will be on an altogether different plan. Formerly large floral plots have been one of the features of the park, but these will be discontinued, and in their place will appear large rustic vases, which will be filled with flowers, the effect being modeled somewhat after that produced at Lincoln Park, Chicago.

VIEWS IN LAKESIDE PARK, MO.

Probably the greatest change in any one of the many attractive features will be made in the grotto, which has always been a favorite place with visitors. In the interior flowing water will drip from crevices in the roof and sides upon plants, ferns and flowers. In front of the grotto stone columns, 3½ ft. square, will be erected, with an old-fashioned arch of moss-covered stone, rustic in appearance. Leading from the columns to the front of a semicircular design will be two stone walls, on the extreme ends of which will be located large vases of flowers. In the stone columns will be cut windows, giving all the appearance of the entrance to an old castle.

One of the principal drawing cards of Lake Hiawatha has been the zoo gardens, and these will be maintained during the coming season on a somewhat extended plan. Additions of rare and interesting birds and animals are to be made.



In addition to the large number of rustic seats on the grounds, about forty swinging seats have this season been placed in shady nooks, where they will be most appreciated. The boathouse will be enlarged, and a toboggan

slide into the lake will be maintained. For the auditorium a large orchestra has been engaged. This orchestra will also furnish music to picnic parties for dances at the park or in the city at reasonable rates. The railway company is a member of the Interstate Vaudeville Association, and the best attractions will be given at this resort. Matinees will be given on excursion days, and performances every evening. The prices for seats are 5 and 10 cents, according to location. A large number of cottages have been built on the grounds, and these will be rented for the summer.

MERRYMEETING PARK, MAINE

Merrymeeting Park is situated near Brunswick, Maine, on the lines of the street railway company, and considerable time and money have been spent in developing it, and it is now one of the most attractive resorts in New England.

The most prominent feature of this park is the casino, which is shown herewith. This building is two and a half stories high, exclusive of the tower. The basement con-

CASINO, MERRYMEETING PARK

tains a kitchen and storerooms, and also accommodations for a large number of bicycles. The first story is divided into a general waiting room, office and a large ball room, with a moveable stage. Here plays and entertainments are given when stormy weather prevents the use of the open-air theater.

The second story is devoted to dining rooms, ladies' parlors, smoking rooms, and a large public dining room. The tower will be used for observation purposes, and also as a roof garden. The building is heated by steam, and brilliantly lighted throughout with electricity. During the summer evenings a special feature will be made of the illumination of the building.

Merrymeeting Park has a frontage of one-quarter of a mile on the Bath road, and extends for nearly one-half a mile along the Androscoggin River. The park has been laid out and the casino built under the direction of Frank M. Blaisdell, of Boston.

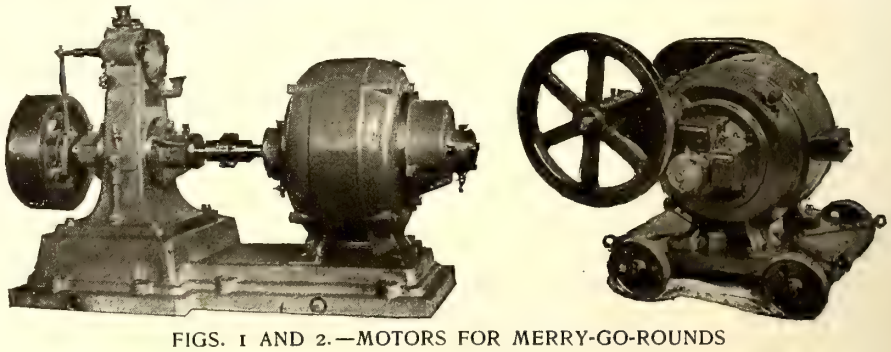
One of the improvements made in the property that is particularly worthy of note is the substitution of a pretty pond for a piece of ground that was formerly an impenetrable alder swamp. This was accomplished by building a dam across a small stream that runs through the park.

In the center of the pond a large pavilion has been placed, which will be used for dancing during the warm summer nights, this arrangement being a particularly agreeable feature. Next winter it is intended to utilize this pond for skating, and arrangements will be made for clearing it of snow and flooding it when the surface of the ice becomes too rough. The grounds have been cleared of a large amount of undergrowth and fallen deadwood, and paths have been laid out in all directions, giving the visitor his choice of a dozen pleasant strolls. Rustic seats and chairs are placed at frequent intervals.

A rustic outdoor theater has been erected in a natural depression in the ground, the seats rising in tiers above the stage. Here the usual out-of-door vaudeville and dramatic amusements will be given. At each side of the stage is a spring of cool water, and attendants serve this water to the spectators during the progress of the plays. This feature is very much appreciated by the public.

The owners of the park have in contemplation numerous other improvements and attractions at this resort, and, during the spring and early summer, lawns, flower beds and shrubbery will be placed in the vicinity of the casino; little ponds will take the place of swampy ravines, summer houses, shelters and observatories will be erected at prominent spots, a large athletic field will be made in the meadow near the river, deer, caribou, moose and elk will be placed in the woods, and swans, ducks and other aquatic birds on the pond and river.

PARK AT ALLENTOWN, PA.



The park of the Allentown & Lehigh Valley Traction Company will open shortly with a large number of improvements and additions. The principal attractions at this place are an open-air theater, where performances are given daily, and a small "zoo." This company has found that a cage of lively monkeys provides one of the most pleasing and amusing attractions that can be found. Crowds will stand and watch the antics of a dozen monkeys for nearly a half-hour, when they would pass by the ordinary park attractions without notice. The company also owns an elephant, which has proven a center of attraction, especially to the children.

ROSS PARK, BINGHAMTON

Ross Park, located at Binghamton, N. Y., opens this year with greater promises than ever before for a successful season. This resort has been laid out on broader lines than the usual run of pleasure resorts, and it is known and patronized by people for miles around. Men have been busy for some time getting the grounds into shape, cleaning up the winter's rubbish and making a number of slight improvements. The company is considering the advisability of building a much larger open-air theater and amusement pavilion, as the present one is not large enough to accommodate the visitors on pleasant days.

Park Attractions

Practically all street railway managers unite in the opinion that there is no better paying attraction for street railway parks than

FIGS. 1 AND 2.—MOTORS FOR MERRY-GO-ROUNDS

merry-go-rounds. The Armitage-Herschell Company, of North Tonawanda, N. Y., is one of the largest manufacturers of machines of this kind in the country, and through many years of experience in the designing and building of merry-go-rounds, has created a very extensive domestic and foreign export trade.

The standard machine built by this concern consists of a steel track, upon which run wheels supporting the machine proper, consisting of sweeps, platforms and lattice work, this in turn supporting four chariots, each capable of seating four passengers, together with the twelve pairs of horses, each of which has an animated and

exhilarating galloping motion. Sixteen chairs are also provided, making the seating capacity of the machine fifty-six persons.

All of the parts of these machines are made in large quantities, by workmen skilled in their particular duties, and upon the interchangeable system. All of the parts are ingeniously fitted and interlocked, so that the whole machine may be assembled in a very short time, and when the various pieces are in place with their bolts turned up, the whole frame work becomes rigid as one piece, thus greatly lengthening the life of the machine by limiting all wear from racking strains.

The rotation of the gallery is obtained by means of a steel cable passing about a groove on the circumference of the machine. This cable is driven by a stationary engine, or where electric power is available by means of an electric motor, either of which is built by this company in the same plant as the gallery, thus assuring that each will be adapted for the other. This method of driving is covered broadly by patents which cover as well the use of the eccentric for giving the horses their galloping motion. The machines can be operated successfully by two men where a permanent stand can be obtained, although it is advisable to have three men when the machine is to be moved from place to place. When, however, the electric motor can be used, one man can operate the gallery successfully, as the electric controller is placed directly upon the machine, so that one man may act as both fare collector and operator, having perfect and absolute control of the motion of the gallery. The motor used for this purpose is shown in Figs. 1 and 2.

As a modification of the standard machine, and to meet a demand for a novelty, a somewhat similar machine is built in which there are three horses abreast instead of two, the number of chariots remaining the same. This increases the capacity of the machine by twelve riders, and increases the earning capacity to the same extent, and is very popular in locations where the capacity of the standard machine is inadequate to the demands for seating capacity.

In addition to the above machines and in order to supply a machine adapted for permanent locations where a large attendance is assured, the "Mountain-Valley" shown in Fig. 3 has been

FIG. 3.—MOUNTAIN VALLEY MERRY-GO-ROUND

evolved and perfected. Upon an undulating track having a rise and fall of 6 ft., are propelled eight gorgeous chariots, each with a seating capacity of twelve passengers. Each chariot is resplendent with massive carving and gorgeous decorations, being studded with beveled mirrors and richly upholstered. The chariots are attached to the portable frame by brass rods and move about a center of magnificent pictures and superb decorations. Over the whole is a canvas top surrounded by a carved valance, resplendent medallion pictures, hand-carved scrolls and beveled mirrors, and supported by heavy brass columns.

With the standard and three-horse abreast machine is furnished an elegant organ about 60 ins. high, 40 ins. long and 25 ins. deep, with trumpets, piccolos and flageolets of very rich and powerful tones, having inside violin and basses, contra basses, and stopped diapason, with two barrels playing eight tunes each of the latest popular airs, also a novelty in the way of a negro image represented as turning the organ which automatically turns its head and bows to the audience as the gallery revolves. The organ furnished with the "Mountain-Valley" is considerably larger and finer than this.

VAUDEVILLE ATTRACTIONS

J. W. Gorman, of Boston, the well-known manager of amusement attractions for parks, states that an increased interest is being felt in the subject of street railway parks this season. Mr. Gorman formed a circuit last year among a large number of street railway parks in the East, and thus gave each one a change of bill every week or oftener, if desired, through the season, with satisfaction to the railway companies. Mr. Gorman has given the subject of entertainments attention for many years, and during this time has made a specialty of out-of-door attractions. After a study of local conditions the only information which he needs from a railway company is how much it is willing to spend on park attractions, and he will then supply the best entertainment for the conditions and prices named. Devoting, as Mr. Gorman does, his entire attention to this one specialty, he is well posted on everything that is needed, and will supply specifications for park theaters or other fittings necessary.

Official Tests of Brakes in New York

The Board of Railroad Commissioners of the State of New York has issued the following notice:

NOTICE TO OWNERS OF BRAKES FOR STREET SURFACE CARS

ALBANY, March 29, 1899.

The board of railroad commissioners of the State of New York will make a test of braking systems for street surface cars, on cars to be furnished for that purpose by the Metropolitan Street Railway Company of New York City. The tests will be made of such braking systems offered as appear to the commission to be practicable. Applications to have braking system tested, and for permits to equip cars for this purpose, must be made on the accompanying blanks. All applications must be accompanied by a drawing, tracing, blue print or photograph showing the system complete; also a full description of the same, setting forth the details of construction, application to car and method of operation.

The cars to be furnished will be eight-wheel cars, with "Brill" maximum traction trucks fitted with G. E. 1000 motors, with non-suspension; driving wheels 30 ins., tread wheels 20 ins. in diameter; length of car-body over all 28 ft; outside measurements of wheel base 17 ft. 6 ins. The railway company will furnish space in its car-house and pit-room for the purpose of fitting up cars, but will not furnish any supplies, labor or machine shop facilities. The general master mechanic of the Metropolitan Street Railway Company will designate the cars to be equipped and the car-house at which the work shall be done.

These tests will be made in any manner the board of railroad commissioners may determine. While the tests are being made only one representative of the applicant will be allowed on the platform on which the brake is operated.

All tests of braking systems for stopping a car will be from a signal on a basis of $\frac{WS^2}{D} = E$.

E = Efficiency of braking system.

W = Weight of car.

D = Distance between point at which signal is given to point of stop.

S = Rate of speed at time of giving signal.

The merits of braking system will be determined on the following points:

First—Emergency stop at —— miles per hour.

Second—Stop at —— miles per hour, without skidding wheels.

Third—Service at —— miles per hour.

Fourth—Ease of manipulation.

Fifth—Reliability of system.

Sixth—Operation of the system by the ordinary motorman.

Seventh—Simplicity of system.

Eighth—Liability of brakes operating when they should not

Ninth—Safety devices in case of failure of any part of braking system.

Distinctive emergency brakes will be tested on their merits and their non-interference with the ordinary brake.

Application for permits to compete and to equip cars should be addressed to C. R. Barnes, electrical expert, railroad commission of the State of New York, Albany, N. Y., and will be received until May 2, 1899.

JOHN S. KENYON.
Secretary State Railroad Commission.

There appear to be three main conditions involved in the "best material" for brake shoes, viz.: that it should be economical in wear itself, economical as regards wear on wheels, and should have a good coefficient of friction. Different men will vary in opinion as to the relative importance of these three conditions.—From paper read at the Atlanta, Ga., Convention, 1894.
